We study photon orbits in the background of (1 + 3)-dimensional static, spherically symmetric geometries. In particular, we have obtained exact analytical solutions to the null geodesic equations for light rays in terms of the Weierstrass function for space-times arising in the context of scale-dependent gravity. The trajectories in the (x, y) plane are shown graphically, and we make a comparison with similar geometries arising in different contexts. The light deflection angle is computed as a function of the running parameter ξ, and an upper bound for the latter is obtained.

I. INTRODUCTION

Light has always been of paramount importance in the history of science. Indeed, over the years considerable progress has been made observing the light reaching our planet from distant sources. To mention just a few, the absorption spectra of chemical elements, the accidental discovery of the cosmic microwave background radiation by Penzias and Wilson [1], and the bending of light during the total solar eclipse in 1919, are only some examples among many others. As far as gravity is concerned, studying the motion of light rays and/or massive test particles in a fixed gravitational background is one of the principal ways to explore the physics of a given gravitational field. For instance, in the case of Einstein’s General Relativity (GR) [2] and Schwarzschild geometry [3], the explanation of the perihelion precession of the planet Mercury around the Sun [4] as well as the bending of light [4] during the total solar eclipse in May of 1919 (for a historical review for the completion of 100 years of that important event and the two British expeditions to Sobral, Brazil, and to Principe Island, Africa, see [5]) comprise two of the classical tests of GR [6].

Moreover, understanding how light propagates through space in the presence of massive bodies is critical to our understanding of the Universe, e.g. to characterize the nature of dark energy and dark matter. Indeed, to understand the gravitational lensing of distant galaxies, we need to know precisely how light bends near the strong gravitational fields of galaxies. This is a central piece of any cosmological model [7], such as the standard ΛCDM model [8].

Despite its beauty and its many successful predictions that have been confirmed over the years, there are still numerous open questions concerning the quantum nature of GR. The quest for a theory of gravity that incorporates quantum mechanics in a consistent way is still one of the major challenges in modern theoretical physics. Most current approaches to the problem found in the literature (for a partial list see e.g. [9–17] and references therein), seem to share one particular property, i.e. the couplings that enter into the action defining one’s favorite model, such as the cosmological constant, the gravitational and electromagnetic couplings etc., become scale dependent (SD) quantities at the level of an effective averaged action after incorporating quantum effects. A posteriori this does not come as a surprise, since scale dependence at the level of the effective action is a generic feature of ordinary quantum field theory.

Due to the complexity of non-linear partial differential equations, analytical methods in most of the cases just cannot work, and most of the gravitational effects can only be understood employing either approximate or numerical methods. Obtaining exact analytic expressions, however, is always desirable for at least two reasons. The first reason is that analytic expressions may serve as test beds for numerical methods, and they are also a good starting point for developing approximate approaches [18]. The second reason is that analytic expressions enable a systematic study of the complete parameter space, and of all possible solutions, the structure and characteristics of which can be explored [18]. This includes the derivation of observable effects, such as the perihelion advance or light deflection. It is only in this case that a systematic study of all effects may be performed.

The orbits of light rays in fixed gravitational backgrounds of certain forms are described by solutions to differential equations of elliptic or hyperelliptic type. The theory of those functions was studied long time ago by Jacobi [19], Abel [20], Riemann [21, 22] and Weierstraß [23]. A review of those achievements as well as a compact description of the complete theory may be found in [24]. In particular, the motion of test particles in the Schwarzschild space-time was completely analyzed by Hagihara using elliptic functions back in 1931 [25]. More recently, over the last 15 years or so, elliptic and hyperelliptic functions have been used to obtain exact analytic solutions to the geodesic equation for well-known geometries, such as Schwarzschild-(anti) de Sitter [26–
the effective energy-momentum tensor is defined by \[ T_{\mu\nu}^{\text{eff}} \]

where \( \Lambda_k \) is the running cosmological constant, while the additional contribution due to the scale-dependent Newton’s constant is computed to be \[ \Delta \mathbf{t}_{\mu\nu} \equiv G_k(\mathbf{g}_{\mu\nu} \Box - \nabla_\mu \nabla_\nu)G_k^{-1}. \]

To close the system of equations, we take advantage of the null energy condition, we accept that \( \mathcal{O}(k(r)) \to \mathcal{O}(r) \), and we only consider the radial variable.

Finally, the scale-dependent Schwarzschild-de Sitter (SdS) solution is found to be \[ f(r) = f_{\text{SdS}}(r) + \frac{\xi}{2M} \left[ 6M - 2r + \frac{3r\xi}{M} (r - 4M) \right. \]

where \( f_{\text{SdS}}(r) \) is the lapse function of the usual SdS spacetime given by \[ f_{\text{SdS}}(r) = 1 - \frac{2M}{r} - \frac{1}{3} \Lambda r^2 \]

with \( M \) being the mass of the object that generates the gravitational field, \( \Lambda \) is the classical cosmological constant, and \( \xi \) is a dimensionless parameter that measures the deviation from the classical theory.

Assuming that \( \xi \ll 1 \), taking the leading terms in \( \xi \) we obtain the approximate expression \[ f(r) \approx f_{\text{SdS}}(r) - \frac{\xi r}{M} \left( 1 - \frac{3M}{r} \right) \]

Therefore in the following we shall consider static, spherically symmetric geometries of the form \[ ds^2 = -f(r)dt^2 + f(r)^{-1}dr^2 + r^2[\theta^2 + \sin^2 \theta d\phi^2] \]

characterized by a lapse function \( f(r) \) of the general form

\[ f(r) = f_{\text{SdS}}(r) + \gamma r + \eta \]

where the parameters \( \gamma, \eta \) may be either positive or negative. Interestingly enough, it turns out that this is a class of geometries including solutions in contexts other than GR and scale-dependent gravity, such as Weyl conformal gravity [59] and massive gravity [60, 61]. For comparison reasons, in the discussion to follow we shall show the photon orbits in the \((x − y)\) plane for all three space-times.

Here we should keep in mind that a regular scale-dependent black hole solution was first obtained in [62] (see also [63]), and the corresponding lapse function is found to be

\[ F(r) = 1 - \frac{2M}{r} \left( 1 + \frac{M \xi}{6r} \right)^{-3} , \]

where \( M \) is the mass of the black hole, and \( \xi \) is the scale-dependent parameter, which measures the deviation from the classical theory. Expanding in powers of \( \xi \) we obtain an approximate expression at leading order in \( \xi \)

\[ F(r) = 1 - \frac{2M}{r} + \frac{M^2 \xi}{r^2} + \mathcal{O}(\xi^2) \]
Notice that at this level of approximation, the geometry looks like the Reissner-Nordström solution [64] for charged black holes in GR, where \( \xi \) plays the role of the electric charge. The orbits of test particles in the background of RN may be found precisely as in the Schwarzschild case [65]. In the present work, for comparison reasons we shall show the photon orbits for this geometry as well.

**B. Geodesic equations**

As already mentioned before, we assume a fixed four-dimensional static, spherically symmetric gravitational background, which takes the general form

\[
 ds^2 = g_{tt} dt^2 - g_{rr} dr^2 - r^2 [d\theta^2 + \sin^2 \theta d\phi^2] \quad (11)
\]

The equation of motion for test particles is given by the geodesic equation [35]

\[
 \frac{d^2 x^\mu}{ds^2} + \Gamma^{\mu}_{\rho\sigma} \frac{dx^\rho}{ds} \frac{dx^\sigma}{ds} = 0 \quad (12)
\]

where \( s \) is the proper time, while the Christoffel symbols \( \Gamma^\mu_{\rho\sigma} \) are computed by [66]

\[
 \Gamma^\mu_{\rho\sigma} = \frac{1}{2} g^{\mu\lambda} \left( \frac{\partial g_{\lambda\rho}}{\partial x^\sigma} + \frac{\partial g_{\lambda\sigma}}{\partial x^\rho} - \frac{\partial g_{\rho\sigma}}{\partial x^\lambda} \right) \quad (13)
\]

The mathematical treatment is considerably simplified by the observation that there are two first integrals of motion (i.e., conserved quantities), precisely as in the Keplerian problem in classical mechanics. To do that, we recognize that for \( \mu = 1 = t \) and \( \mu = 4 = \phi \) the geodesic equations take the simple form

\[
 0 = \frac{d}{ds} \left( g_{tt} \frac{dt}{ds} \right) \quad (14)
\]

\[
 0 = \frac{d}{ds} \left( r^2 \frac{d\phi}{ds} \right) \quad (15)
\]

Taking advantage of the last two expressions, we can introduce the following conserved quantities

\[
 E \equiv g_{tt} \frac{dt}{ds}, \quad L \equiv r^2 \frac{d\phi}{ds} \quad (16)
\]

The above two quantities, \( \{E, L\} \), are identified to the energy and angular momentum, respectively. Moreover, assuming a motion on the \((x-y)\) plane the geodesic equation corresponding to the \( \theta \) index is automatically satisfied.

Thus, the only non-trivial equation is the one corresponding to \( \mu = 2 = r \) [35]

\[
 \left( \frac{dr}{ds} \right)^2 = \frac{1}{g_{tt}g_{rr}} \left[ E^2 - g_{tt} \left( \epsilon + \frac{L^2}{r^2} \right) \right] \quad (17)
\]

which may be also obtained from [35]

\[
 g_{\mu\nu} \frac{dx^\mu}{ds} \frac{dx^\nu}{ds} = \epsilon \quad (18)
\]

where \( \epsilon = 1 \) for massive test particles, and \( \epsilon = 0 \) for light rays.

At this point is advantageous to introduce an effective potential

\[
 V_{\text{eff}}^2 = g_{tt} \left( \epsilon + \frac{L^2}{r^2} \right) \quad (19)
\]

after which the equation of motion takes the final simple form [35]

\[
 \left( \frac{dr}{ds} \right)^2 = \frac{1}{g_{tt}g_{rr}} \left[ E^2 - V_{\text{eff}}^2 \right] \quad (20)
\]

Finally, the orbit is found obtaining \( r \) as a function of \( \phi \), which is found to be

\[
 \left( \frac{dr}{d\phi} \right)^2 = \left( \frac{dr/ds}{d\phi/ds} \right)^2 = \frac{r^4}{L^2 g_{tt}g_{rr}} \left[ E^2 - g_{tt} \left( \epsilon + \frac{L^2}{r^2} \right) \right] \quad (21)
\]

When the Schwarzschild ansatz is used (as in all cases of interest here), the latter expression is simplified to be

\[
 R(r) \equiv \left( \frac{dr}{d\phi} \right)^2 = \frac{r^4}{L^2} \left[ E^2 - g_{tt} \left( \epsilon + \frac{L^2}{r^2} \right) \right] \quad (22)
\]

The differential equation, since it is of first order, must be supplemented by the appropriate initial condition. Clearly, the precise shape of the orbits depends on i) the background geometry, ii) the values of \((E, L)\), and iii) the initial condition.

**III. EXACT ANALYTIC SOLUTIONS**

In this section, first we shall obtain the general expression for the orbits in terms of the Weierstraß function [23], and after that we shall show graphically the orbits in the \((x-y)\) plane for different values of the photon energy and different initial conditions, and for each geometry separately.

1. Case I

The general case take advantage of the metric components as follows

\[
 g_{tt} = f(r) = 1 - \frac{2M}{r} - \frac{1}{3} \Lambda r^2 + \gamma r + \eta \quad (23)
\]

\[
 g_{rr} = f(r)^{-1} \quad (24)
\]

We recall that the above lapse function arises in several non-standard theories of gravity, such as Weyl gravity.
and scale-dependent gravity [38, 39, 46, 48] at leading order in $\xi$.

Focusing on photon orbits we set $\epsilon = 0$, and making the change of variable $u = 1/r$, the equation for the trajectories $u(\phi)$ is written down as follows

$$
\left( \frac{du}{d\phi} \right)^2 = P_3(u) = b_3 u^3 + b_2 u^2 + b_1 u + b_0
$$

where the corresponding coefficients are computed to be

$$
b_3 = 2M \quad (26)
$$

$$
b_2 = -(1 + \eta) \quad (27)
$$

$$
b_1 = -\gamma \quad (28)
$$

$$
b_0 = \frac{1}{3} \Lambda + \left( \frac{E}{L} \right)^2 \quad (29)
$$

and

$$
\frac{dy}{d\phi} = 4y^3 - g_2 y - g_3 \quad (33)
$$

In order to obtain the solution in terms of the Weierstraß function, $\wp(\phi - \phi_{in}; g_2, g_3)$, first we perform a linear transformation of the form $u(\phi) = Ay(\phi) + B$, where the coefficients $\{A, B\}$ are given by

$$
A = \frac{4}{b_3} \quad (31)
$$

$$
B = -\frac{b_2}{3b_3} \quad (32)
$$

The initial equation $(du/d\phi)^2 = P_3(u)$ takes the form [67]

$$
\left( \frac{dy}{d\phi} \right)^2 = 4y^3 - g_2 y - g_3 \quad (33)
$$

where the Weierstraß cubic invariants $g_2, g_3$ can be found [67]

$$
g_2 = \frac{1}{16} \left( \frac{4b_2^2}{3} - 4b_1 b_3 \right) \quad (34)
$$

$$
g_3 = \frac{1}{16} \left( \frac{b_1^2b_3 - b_0 b_3^2 - 2b_2^3}{27} \right) \quad (35)
$$

To obtain a complete solution of the Weierstraß function, $\wp(\phi - \phi_{in}; g_2, g_3)$, the integration constant, $\phi_{in}$, must be determined. The last can be made by imposing the initial condition $u(\phi_0) = u_0$. The solution to the initial equation is then given by

$$
r(\phi) = \frac{1}{Ay(\phi) + B} = \frac{1}{A \wp(\phi - \phi_{in}; g_2, g_3) + B} \quad (36)
$$

provided that the discriminant

$$
\Delta \equiv g_2^3 - 27g_3^2 \quad (37)
$$

does not vanish, since when $\Delta = 0$ the case is singular [26]. For more details on the Weierstraß function and its properties, the interested reader may want to consult [68]. For those who are more familiar with the Jacobi elliptic functions, the Weierstraß function may be expressed in terms of them, see e.g. [69].

We recall that the formalism used up to now is valid for a family of geometries, which are static, spherically symmetric solutions in massive gravity, in Weyl conformal gravity and in scale-dependent gravity (Schwarzschild-de Sitter with varying cosmological constant and Newton’s constant). To investigate those cases, we will show below in a series of figures both the effective potential for photons as well as the corresponding orbits for each case, varying the energy, the initial angle and the running parameter $\xi$.

In Fig. (1) we show the effective potential for each geometry, for different values of the energy. Subsequently, in Fig. (2) we show the trajectories for the scale-dependent Schwarzschild-de Sitter black hole. Besides, in figures (3) and (4) we show the photon orbits in massive and Weyl gravity, varying the photon energy, $E$, and the initial angle $\phi_{in}$.

We have considered four different values of the energy, and for each one of those, we have assumed three different values of the initial angle. The orbits hit the $(0,0)$ point and then bounce off, exhibiting a cardioid shape, which is deformed varying $E$ and $\phi_{in}$. The deformation becomes more pronounced as the photon energy approaches the maximum of the effective potential.

Finally, in Fig. (5) we show the impact of the running parameter $\xi$ on the shape of the photon orbits (in the case of Schwarzschild-de Sitter geometry) setting $L = 10, M = 1, \Lambda = 0.01, E = 1$, and varying $\xi = 0.01, 0.04, 0.07$ from outwards to inwards.

2. Case II

In this case, the corresponding metric components are given by

$$
g_{tt} = F(r) = 1 - \frac{2M}{r} + \frac{M^2\xi}{r^2} \quad (38)
$$

$$
g_{rr} = F(r)^{-1} \quad (39)
$$

Similarly to the previous case, we can use the following change of variable $u = 1/r$, and also setting $\epsilon = 0$, the equation for the trajectories $u(\phi)$ is written down as follows

$$
\left( \frac{du}{d\phi} \right)^2 = P_4(u) = -M^2\xi u^4 + 2Mu^3 - u^2 + (E/L)^2 \quad (40)
$$

with $P_4(u)$ being a fourth degree polynomial in $u$. We can simplify the problem reducing the order of the polynomial if we take advantage of a single root of $P_4(u)$. Thus, we can set $u = (1/z) + 1$ to get a new equation for
FIG. 1: Effective potential for photons in the case of the class of geometries including three space-times considered in the first case setting \( L = 10, M = 1, \Lambda = 0.01 \). We plot, in each panel, the effective potential for photons and different energy regimes: i) **Left Panel**: Scale-dependent Schwarzschild-de Sitter setting \( \xi = 0.05 \). ii) **Middle Panel**: Massive gravity setting \( \gamma = 0.005, \eta = 0 \). iii) **Right Panel**: Weyl conformal gravity setting \( \gamma = 0.005, \eta = -0.15 \).

FIG. 2: Photon orbits in the \((x - y)\) plane \((0 \leq \phi \leq 2\pi)\) in the case of scale-dependent Schwarzschild-de Sitter geometry setting \( L = 10, M = 1, \Lambda = 0.01, \xi = 0.05 \). To show the impact of the photon energy and initial conditions, we take four different energies, and vary the initial angle as follows: i) **Top-left Panel**: \( E = 0.80 \) and \( \phi_{ini} = \{0.5, 1.0, 1.5\} \) (short dashing blue line, dashing red line and long dashing green line, respectively). ii) **Top-right Panel**: \( E = 1.60 \) and \( \phi_{ini} = \{0.5, 1.0, 1.5\} \) (short dashing blue line, dashing red line and long dashing green line, respectively). iii) **Bottom-left Panel**: \( E = 1.85 \) and \( \phi_{ini} = \{0.5, 1.0, 1.5\} \) (short dashing blue line, dashing red line and long dashing green line, respectively). iv) **Bottom-right Panel**: \( E = 2.50 \) and \( \phi_{ini} = \{0.5, 1.0, 1.5\} \) (short dashing blue line, dashing red line and long dashing green line, respectively).

where now the coefficients are computed to be

\[
\left( \frac{dz}{d\phi} \right)^2 = b_3 z^3 + b_2 z^2 + b_1 z + b_0 \quad \quad (41)
\]

\[
b_3 = -4l^3 M^2 \xi + 6l^2 M - 2l \quad \quad (42)
\]

\[
b_2 = -6l^2 M^2 \xi + 6l M - 1 \quad \quad (43)
\]

\[
b_1 = 2M - 4l M^2 \xi \quad \quad (44)
\]

\[
b_0 = -M^2 \xi \quad \quad (45)
\]
The new equation may be now solved exactly as before, and therefore we find for $r(\phi)$ the expression

$$r(\phi) = \frac{A \phi(\phi - \phi_{ini}; g_2, g_3) + B}{1 + l [A \phi(\phi - \phi_{ini}; g_2, g_3) + B]} \quad (46)$$

We then show in Fig. (6) the effective potential for photons, and after that we plot the photon orbits for different values of photon energy and initial angle $\phi_{ini}$, see Fig. (7). Here, too, we have considered four different values of $E$, and three different values of $\phi_{ini}$. All the features observed in the geometries discussed before are observed here as well.

Before we conclude our work, let us briefly discuss some applications and observational consequences based on the formalism used in the present article. In the strong field limit [70, 71] analytic expressions may be obtained, and observables related to gravitational lensing, such as image angle and magnification, are computed in terms of the strong deflection coefficients, see e.g. [63, 72]. For well-known geometries, such as the Schwarzschild and Reissner-Nordström space-times, the expressions for the strong deflection coefficients are shown in the Appendix of [73]. A detailed investigation of the strong field limit for the geometries discussed here lies outside the scope of this work. It would be interesting, however, to address that issue, and we certainly hope to be able to do so in a forthcoming publication.

Finally, in the discussion to follow we shall use the data on the solar eclipse occurred in 1919, which was measured by the Eddington expedition [74], and was reanalyzed much later in [75], to constrain the running parameter $\xi$, which is the only free parameter in scale-dependent gravity as the cosmological constant as well as the solar
mass are known.

The deflection angle is given by [72]

$$\alpha = -\pi + 2 \int_{r_0}^{\infty} \frac{dr}{\sqrt{P_3(r)}}$$  \hspace{1cm} (47)$$

where $r_0$ is the closest distance to the deflecting object, determined by $dr/d\phi = 0$, or equivalently, $P_3(r_0) = 0$.

To compute the integral it is more convenient to introduce a new dimensionless parameter, $z \equiv 1 - r_0/r$. The deflection angle now is given by

$$\alpha = -\pi + \int_{0}^{1} \frac{2r_0 dz}{\sqrt{c_1 z + c_2 z^2 + c_3 z^3}}$$  \hspace{1cm} (48)$$

where the coefficients $c_i$ are found to be

$$
\begin{align*}
c_1 &= -6Mr_0 + 2r_0^2 + \xi r_0^2 (6r_0^2 - r_0/M) \hspace{1cm} (49) \\
c_2 &= 6Mr_0 - 2r_0^2 - 3\xi r_0^2 \hspace{1cm} (50) \\
c_3 &= -2Mr_0 \hspace{1cm} (51)
\end{align*}
$$

The theoretical prediction for the deflection angle as a function of the running parameter, $\xi$, assuming an impact parameter

$$b \equiv L/E = R_\odot = 6.96 \times 10^8 \text{ m}$$  \hspace{1cm} (52)$$

is shown in Fig. (8). The strip from 1.79 to 2.01 denotes the allowed observational range, $\alpha = 1.9 \pm 0.11$ [5]. Our results show that $\xi$ must not exceed the value $\xi_* = 2.6 \times 10^{-12}$. Therefore we obtain for the first time here an upper bound for the running parameter

$$\xi \leq 2.6 \times 10^{-12}.$$  \hspace{1cm} (53)
IV. CONCLUSION

We have studied the orbits of light rays in the gravitational background of (1+3)-dimensional geometries with spherical symmetry arising in theories other than General Relativity, such as scale-dependent gravity, massive gravity and Weyl conformal gravity. In particular, we have obtained exact analytical solutions to the null geodesic equations in terms of the Weierstraß function. The effective potential for photons as well as the trajectories in the \((x-y)\) plane have been shown graphically for several values of the photon energy, the integration constant (initial conditions) and the running parameter. In the case of scale-dependent Schwarzschild-de Sitter geometry, the light deflection angle is computed as a function of the running parameter, and an upper bound for the latter is obtained.

This work opens to us the possibility of testing such classes of alternative theories of gravity at any scale, for instance, around neutron stars and astrophysical black holes, or around super-massive black holes at the center of galaxies. More importantly, it may be used to generalize the gravitational lensing of galaxies, which is fundamental to further understand the content as well as other important aspects of the Universe.

FIG. 8: Prediction for light deflection near our Sun in the case of scale-dependent Schwarzschild-de Sitter geometry. We show the deflection angle (in arcsec) as a function of the running parameter $\xi$. The allowed strip $1.9 \pm 0.11$ is shown as well.

merzahl, Phys. Rev. D 78 (2008) 124018 Erratum: [Phys. Rev. 79 (2009) 029901] Addendum: [Phys. Rev. D 79 (2009) no.2, 029901] [arXiv:0812.2428 [gr-qc]].
