Glucocorticoid receptors modulate mitochondrial function

A novel mechanism for neuroprotection

Key words: glucocorticoid, nuclear receptor, mitochondria, Bcl-2, steroid, plasticity, mood disorders, neuroprotection

It has become increasingly clear that glucocorticoid (GC) signaling not only comprises classic nuclear receptor binding—that is, glucocorticoid receptors (GRs) to their response element in the nucleus—but also involves rapid, non-genomic efforts to regulate signaling cascades and other cell functions in the cytoplasm as well as other cell organelles. In a recent study, we found that GRs form a complex with B-cell lymphoma 2 (Bcl-2), translocate to mitochondria in response to corticosterone (CORT), and modulate mitochondrial calcium and oxidation in an inverted "U"-shaped manner. It is also well established that steroid and thyroid hormone receptors regulate mitochondrial function to protect cells against various challenges and modulate synaptic plasticity. Here, we explore how such work reveals a fundamental mechanism whereby GCs regulate mitochondrial functions, and provides a mechanistic basis for therapeutic methods to rescue mitochondrial dysfunction during chronic stress or related psychiatric and neurodegenerative disorders.

Glucocorticoids (GCs) act through their nuclear receptors in the brain to influence behavior and physiology.¹,² In addition to their well-known genomic effects on gene transcription, GCs also exert rapid, non-genomic effects on neurons in the brain.³ Accumulating data have also shown that certain receptors traditionally considered to be nuclear receptors, particularly glucocorticoid receptors (GRs) translocate into mitochondria and modulate mitochondrial gene expression.⁴-⁶ However, the molecular mechanism of this regulation remains unclear. Recently, we found that in rat brain cells treated with corticosterone (CORT), GRs latched onto B-cell lymphoma 2 (Bcl-2), a protein that affects cytochrome C and calcium release from mitochondria. This GR/Bcl-2 complex moves into mitochondria and regulates mitochondrial functions in an inverted "U"-shaped manner (Fig. 1). Specifically, short-term exposure to CORT enhanced mitochondrial functions, while high doses or long-term treatment with CORT decreased levels of GRs and Bcl-2 in mitochondria (Fig. 1). Similar results occur in rats exposed to chronic CORT.⁷

Such work suggests that, under physiological conditions, GCs enhance mitochondrial functions to provide cells with more energy for coping with and adapting to acute challenges. However, chronic stress may lead to chronically elevated levels of GCs, which in turn may reduce cell functioning via the interaction between GRs/Bcl-2 and mitochondria (Fig. 1). The decrease in proper cell function may contribute to the pathophysiology of several stress-related mental disorders, including major depressive disorder (MDD), and post-traumatic stress disorder (PTSD).

How Does the GR Protein Complex Translocate to the Mitochondria?

Previous studies have shown that GRs form protein complexes with heat shock protein 70/90 (HSP70/90) and Bcl-2-associated athanogene (Bag-1) in response to GC treatment.⁸-¹⁰ It is also well established that the proteins targeting mitochondria associate with chaperones that help in their mitochondrial translocation. One of the major chaperones in this category is HSP70.¹¹,¹² Based on the signal information in the precursor protein, it could be targeted to any of the four locations: the mitochondrial outer membrane, the mitochondrial inner membrane, the intermembrane space, or the mitochondrial matrix.¹³ Furthermore, Bcl-2 is one of the tail-anchored molecules localized at the outer membrane of mitochondria.¹⁴ In contrast, GRs travel to the matrix of the mitochondria and modulate mitochondria-coded protein expression.¹⁵ It is possible that the GR/Bcl-2 complex shares the machinery for mitochondrial protein translocation by binding to HSP70/90 chaperone proteins, in much the same manner that estrogen receptors (ERs) can.¹⁶
Glucocorticoid receptors modulate mitochondrial function

Bag-1, which binds to Bcl-2, is also a GR chaperone protein. Bag-1 attenuates nuclear translocation of GR, activates the extracellular receptor kinase (ERK) pathway, and potentiates the anti-apoptotic function of Bcl-2. In addition, Bag-1 transgenic mice showed less anxious-like behavior on the elevated plus maze test and more resilience in recovering from learned helplessness behavior and amphetamine-induced manic-like behaviors. Because Bag-1 binds to both Bcl-2 and GRs, its role in GR/Bcl-2 complex translocation to mitochondria becomes a key issue.

Why Are Bcl-2 Family Genes a Key Modulator for Mitochondrial Function and Neuroprotection in Response to GCs?

Bcl-2 family proteins play a key role in apoptosis because of their ability to regulate the integrity of the mitochondrial outer membrane. Proteins such as Bcl-2 and Bcl-xL prevent the release of apoptogenic proteins from mitochondria and therefore protect against outer membrane permeabilization. Pro-apoptotic Bcl-2 family members—such as Bax and Bak—induce outer membrane permeabilization and cause the release of pro-apoptotic factors from mitochondria. The Bcl-2 proteins act either alone or together with other proteins like Bak to regulate the permeability of the outer membrane. Our recent findings indicate that GRs form a complex with Bcl-2 in response to CORT treatment and, furthermore, translocate with Bcl-2 into mitochondria. This may be a critical step in blocking pore formation in the mitochondrial outer membrane. Therefore, calcium and cytochrome C release from the mitochondria would be attenuated (Fig. 1).

Additional findings have shown that Bcl-2 overexpression leads to enhanced mitochondrial calcium levels. Notably, increased calcium levels operate mitochondrial metabolic checkpoints. Specifically, the aspartate/glutamate metabolite carriers are activated by calcium; in turn, recombinant expression of wild-type aspartate/glutamate metabolite carriers enhances adenosine triphosphate (ATP) production in response to cell stimulation.

Conclusion and Future Directions

The regulation of neuronal mitochondrial function by steroids is directly linked to neuroprotection and synaptic plasticity. Furthermore, the central role that mitochondria play in neurodegeneration and psychiatric disorders has become apparent over the last decade as the molecular mechanisms that influence both neuronal death and neuroplasticity have been increasingly elucidated. Accumulating evidence regarding mitochondrial translocation and the function of traditional “nuclear receptors” has revealed interesting and novel mechanisms in mitochondria that are regulated by steroids—particularly GCs—but also estradiol. However, the study of steroid hormone receptor regulation of mitochondrial function is still in its infancy. Future research will be needed to address several unanswered questions. For instance, what is the protective molecule that enhances GR/Bcl-2 trafficking to mitochondria in response to GCs? Is translocation of Bcl-2 family genes to mitochondria necessary for the modulation of mitochondrial functions by GCs? Do other traditional nuclear receptors form protein complexes with the Bcl-2 family of genes? The new knowledge gained from such studies will be instrumental in understanding the protection or dysfunction that steroid hormone receptors may exert via the regulation of mitochondrial functions by GCs.
