Casas-Ibarra Parametrization and Unflavored Leptogenesis

Abstract

The Casas-Ibarra parametrization is a description of the Dirac neutrino mass matrix $M_D$ in terms of the neutrino mixing matrix $V$, an orthogonal matrix $O$ and the diagonal mass matrices of light and heavy Majorana neutrinos in the type-I seesaw mechanism. Because $M_D^\dagger M_D$ is apparently independent of $V$ but dependent on $O$ in this parametrization, a number of authors have claimed that unflavored leptogenesis has nothing to do with CP violation at low energies. Here we question this logic by clarifying the physical meaning of $O$. We establish a clear relationship between $O$ and the observable quantities, and find that $O$ does depend on $V$. We show that both unflavored leptogenesis and flavored leptogenesis have no direct connection with low-energy CP violation.

Very compelling evidence for finite neutrino masses and large neutrino mixing angles has been achieved from solar [1], atmospheric [2], reactor [3] and accelerator [4] neutrino oscillation experiments. This exciting breakthrough opens a new window to physics beyond the standard electroweak model, because the standard model itself only contains three massless neutrinos whose flavor states $\nu_\alpha$ (for $\alpha = e, \mu, \tau$) and mass states $\nu_i$ (for $i = 1, 2, 3$) are identical. A very natural and elegant way of generating non-zero but tiny masses $m_i$ for $\nu_i$ is to extend the standard model by introducing three right-handed neutrinos and allowing lepton number violation. In this case, the $SU(2)_L \times U(1)_Y$ gauge-invariant mass terms of charged leptons and neutrinos are given by

$$-\mathcal{L}_{\text{mass}} = \overline{l_L} Y_l H E_R + \overline{l_L} Y_\nu \tilde{H} N_R + \frac{1}{2} \overline{N_R} M_R N_R + \text{h.c.} ,$$

where $\tilde{H} \equiv i\sigma_2 H^*$, $l_L$ denotes the left-handed lepton doublet, and $M_R$ is the mass matrix of right-handed neutrinos. After spontaneous gauge symmetry breaking, we are left with the charged-lepton mass matrix $M_l = Y_l v$ and the Dirac neutrino mass matrix $M_D = Y_\nu v$, where $v \simeq 174$ GeV is the vacuum expectation value of the neutral component of the Higgs doublet $H$. The scale of $M_R$ can be much higher than $v$, as right-handed neutrinos belong to the $SU(2)_L$ singlet and are not subject to electroweak symmetry breaking. It is therefore natural to obtain the effective mass matrix for three light neutrinos [5]:

$$M_\nu \approx -M_D M_R^{-1} M_D^T .$$

Such a relation is commonly referred to as the type-I seesaw mechanism. Let us denote the mass states of three right-handed neutrinos and their corresponding masses as $N_i$ and $M_i$ (for $i = 1, 2, 3$), respectively. Then Eq. (2) implies $m_i \sim v^2 / M_i$ as a naive result, which explains why $m_i$ is small but non-vanishing. Note that both light and heavy neutrinos are Majorana particles in this seesaw picture. Without loss of generality, one usually chooses the basis with both $Y_l$ (or $M_l$) and $M_R$ being diagonal, real and positive (i.e., $M_l = \text{Diag}\{m_e, m_\mu, m_\tau\}$ and $M_R = \tilde{M}_N \equiv \text{Diag}\{M_1, M_2, M_3\}$). In this basis, Casas and Ibarra (CI) proposed an interesting parametrization of $M_D$ [6]:

$$M_D \approx iV \sqrt{\tilde{M}_\nu} O \sqrt{\tilde{M}_N} ,$$

where $V$ is the $3 \times 3$ neutrino mixing matrix which can be obtained from the diagonalization of $M_\nu$ (i.e., $V^\dagger M_\nu V^* = \tilde{M}_\nu \equiv \text{Diag}\{m_1, m_2, m_3\}$) \footnote{Note that we have tentatively ignored tiny differences between the eigenvalues of $M_R$ (or $M_\nu$) and the physical masses $M_i$ (or $m_i$). See the next section for a detailed discussion.}, and $O$ is a complex orthogonal matrix.

Associated with the above seesaw mechanism, the leptogenesis mechanism [7] may naturally work to account for the cosmological matter-antimatter asymmetry via the CP-violating and out-of-equilibrium decays of $N_i$ and the $(B - L)$-conserving sphaleron processes [8]. The CP-violating asymmetry between $N_i \rightarrow l + H^c$ and $N_i \rightarrow l + H$ decays, denoted as $\varepsilon_i$ (for $i = 1, 2, 3$), has been calculated in the so-called single flavor approximation (i.e., the final-state lepton flavors are not distinguished and are simply summed) [9]:

1
After spontaneous symmetry breaking, the mass terms in Eq. (1) turn out to be
\[ -\mathcal{L}_{\text{mass}} = \bar{E}_L M_I E_R + \frac{1}{2} \left( \nu_L N_R^T \right) \begin{pmatrix} 0 & M_D^T \\ M_D & M_R \end{pmatrix} \begin{pmatrix} \nu_L^T \\ N_R \end{pmatrix} + \text{h.c.}, \] (6)
where \( E \) and \( \nu_L \) represent the column vectors of \((e, \mu, \tau)\) and \((\nu_e, \nu_\mu, \nu_\tau)_L\), respectively. The overall 6×6 neutrino mass matrix in Eq. (6) can be diagonalized by a unitary transformation:
\[ \begin{pmatrix} V \\ S \\ U \end{pmatrix}^T \begin{pmatrix} 0 & M_D^T \\ M_D & M_R \end{pmatrix} \begin{pmatrix} V \\ S \\ U \end{pmatrix} = \begin{pmatrix} \tilde{M}_\nu \\ 0 \end{pmatrix} \begin{pmatrix} 0 & \tilde{M}_N \end{pmatrix}, \] (7)
where \( \tilde{M}_\nu = \text{Diag}\{m_1, m_2, m_3\} \) and \( \tilde{M}_N = \text{Diag}\{M_1, M_2, M_3\} \) have been defined before. After this diagonalization, the flavor states of light neutrinos \((\nu_\alpha \text{ for } \alpha = e, \mu, \tau)\) can be expressed in terms of the mass states of light and heavy neutrinos \((\nu_i \text{ and } N_i \text{ for } i = 1, 2, 3)\), and thus the standard charged-current interactions between \(\nu_\alpha\) and \(\alpha\) (for \(\alpha = e, \mu, \tau\)) can be written as
\[ -\mathcal{L}_{\text{cc}} = \frac{g}{\sqrt{2}} \left( \nu \mu \tau \right)_L \gamma^\mu \left[ V \begin{pmatrix} \nu_1 \\ \nu_2 \\ \nu_3 \end{pmatrix}_L + R \begin{pmatrix} N_1 \\ N_2 \\ N_3 \end{pmatrix}_L \right] W^\mu - \text{h.c.}, \] (8)
in the basis of mass states. So \( V \) is just the neutrino mixing matrix responsible for neutrino oscillations, while \( R \) describes the strength of charged-current interactions between \((e, \mu, \tau)\)
and \((N_1, N_2, N_3)\). \(V\) and \(R\) are correlated with each other through \(VV^\dagger + RR^\dagger = 1\). Hence \(V\) itself is not exactly unitary in the type-I seesaw mechanism and its deviation from unitarity is simply characterized by non-vanishing \(R\).

Because both \(V\) and \(R\) are well-defined in Eq. (8), they can be used to understand the physical meaning of \(O\) in the CI parametrization. To do so, we first derive the seesaw relation from Eq. (7). The latter yields

\[
V \tilde{M}_\nu V^T + R \tilde{M}_N R^T = 0 ,
\]

and

\[
S \tilde{M}_\nu S^T + U \tilde{M}_N U^T = M_R .
\]

If Eq. (7) is rewritten as

\[
\begin{pmatrix} 0 & M_D \\ M_D^T & M_R \end{pmatrix} \begin{pmatrix} V & R \\ S & U \end{pmatrix}^* = \begin{pmatrix} V & R \\ S & U \end{pmatrix} \begin{pmatrix} \tilde{M}_\nu & 0 \\ 0 & \tilde{M}_N \end{pmatrix} ,
\]

we can directly obtain the exact results

\[
R = M_D U^* \tilde{M}_N^{-1} ,
\]

and

\[
S^* = M_D^{-1} V \tilde{M}_\nu .
\]

Let us substitute Eqs. (12) and (13) into Eqs. (9) and (10), respectively. Then we arrive at

\[
V \tilde{M}_\nu V^T = -M_D \left(U^* \tilde{M}_N^{-1} U^\dagger \right) M_D^T ,
\]

and

\[
M_R = U \tilde{M}_N U^T + \left(M_D^{-1} \right)^* V^* \tilde{M}_\nu V^\dagger \left(M_D^{-1} \right)^\dagger \approx U \tilde{M}_N U^T .
\]

The excellent approximation made in Eq. (15) implies that \(U\) is essentially unitary. Taking \(U\) to be unitary and combining Eqs. (14) and (15), we obtain

\[
M_\nu \equiv V \tilde{M}_\nu V^T \approx -M_D M_R^{-1} M_D^T ,
\]

where \(V\) is also unitary in this approximation. Eq. (16) reproduces the seesaw formula given in Eq. (2). It is obvious that \(R \sim S \sim O(M_D/M_R)\) holds, and thus the seesaw relation actually holds up to the accuracy of \(O(R^2)\) [16].

Now we look at the orthogonal matrix \(O\) in the CI parametrization. Given the basis where \(M_R\) is diagonal, real and positive, Eq. (15) implies that \(M_R \approx \tilde{M}_N\) and \(U \approx 1\) are very good approximations. In this case, we get \(M_D \approx R \tilde{M}_N\) from Eq. (12). Substituting this relation into Eq. (3), we obtain

\[
O \approx -i \sqrt{\tilde{M}_\nu^{-1}} V^\dagger M_D \sqrt{\tilde{M}_N^{-1}} \approx -i \sqrt{\tilde{M}_\nu^{-1}} V^\dagger R \sqrt{\tilde{M}_N} ,
\]

4
which shows that $O$ is definitely dependent on $V$. It is worth remarking that both $V$ and $R$, which are respectively associated with the charged-current interactions of light and heavy Majorana neutrinos, have clear physical meaning. Hence it seems improper to draw the conclusion from Eq. (5) that unflavored leptogenesis is independent of low-energy neutrino mixing and CP violation described by $V$. If Eq. (17) is substituted into Eq. (5), however, we shall arrive at a much simpler expression

$$M_D^\dagger M_D \approx \hat{M}_N R^\dagger R \hat{M}_N.$$  

(18)

This result is actually straightforward, just because of $M_D \approx R \hat{M}_N$. It apparently has nothing to do with $V$. So the question becomes whether unflavored leptogenesis depends on $V$ through $R$. We have known that $V$ is correlated with $R$ via the exact seesaw relation in Eq. (9) and the normalization condition $VV^\dagger + RR^\dagger = 1$. To see this correlation more clearly, one has to adopt an explicit and self-consistent parametrization of $V$ and $R$.

Here we make use of the parametrization of $V \equiv AV_0^\dagger$ and $R$ advocated in Ref. [17]:

$$V_0 = \begin{pmatrix}
    c_{12} c_{13} & \hat{s}_{12} c_{13} & \hat{s}_{13} c_{13} \\
    -\hat{s}_{12} c_{23} - c_{12} \hat{s}_{13} \hat{s}_{23} & c_{12} c_{23} - \hat{s}_{12} \hat{s}_{13} \hat{s}_{23} & c_{13} \hat{s}_{23} \\
    \hat{s}_{12} c_{23} - c_{12} \hat{s}_{13} \hat{s}_{23} & -c_{12} \hat{s}_{23} - \hat{s}_{12} \hat{s}_{13} \hat{s}_{23} & c_{13} c_{23}
\end{pmatrix},$$  

(19)

and

$$A = \begin{pmatrix}
    c_{14} c_{15} c_{16} & 0 & 0 \\
    -c_{14} c_{15} \hat{s}_{16} \hat{s}_{26} & c_{14} \hat{s}_{15} \hat{s}_{25} \hat{s}_{26} & c_{14} \hat{s}_{15} \hat{s}_{25} \hat{s}_{26} \\
    -c_{14} \hat{s}_{14} \hat{s}_{24} c_{25} c_{26} & 0 & 0 \\
    -c_{14} \hat{s}_{15} \hat{s}_{25} \hat{s}_{26} \hat{s}_{36} + c_{14} \hat{s}_{15} \hat{s}_{25} \hat{s}_{26} \hat{s}_{36} & -c_{14} \hat{s}_{15} \hat{s}_{25} \hat{s}_{36} & c_{14} \hat{s}_{15} \hat{s}_{25} \hat{s}_{36} \\
    -c_{14} \hat{s}_{15} \hat{s}_{25} \hat{s}_{26} \hat{s}_{36} + c_{14} \hat{s}_{15} \hat{s}_{25} \hat{s}_{26} \hat{s}_{36} & -c_{14} \hat{s}_{15} \hat{s}_{25} \hat{s}_{36} & c_{14} \hat{s}_{15} \hat{s}_{25} \hat{s}_{36} \\
    +c_{14} \hat{s}_{14} \hat{s}_{24} \hat{s}_{25} \hat{s}_{35} \hat{s}_{36} & -c_{14} \hat{s}_{14} \hat{s}_{24} \hat{s}_{34} \hat{s}_{35} \hat{s}_{36} & 0
\end{pmatrix},$$

$$R = \begin{pmatrix}
    \hat{s}_{14} c_{15} c_{16} & \hat{s}_{15} c_{16} & \hat{s}_{16} \\
    -\hat{s}_{14} c_{15} \hat{s}_{16} \hat{s}_{26} & -\hat{s}_{15} \hat{s}_{26} + c_{15} \hat{s}_{26} & \hat{s}_{16} \\
    +c_{14} \hat{s}_{24} \hat{s}_{25} c_{26} & -c_{14} \hat{s}_{24} \hat{s}_{25} c_{26} & \hat{s}_{16} \\
    -\hat{s}_{14} c_{15} \hat{s}_{16} \hat{s}_{26} + \hat{s}_{14} \hat{s}_{15} \hat{s}_{25} \hat{s}_{26} \hat{s}_{36} & -\hat{s}_{15} \hat{s}_{16} \hat{s}_{26} + c_{15} \hat{s}_{16} \hat{s}_{26} & \hat{s}_{16} \\
    -\hat{s}_{14} \hat{s}_{15} \hat{s}_{25} \hat{s}_{36} - c_{14} \hat{s}_{24} \hat{s}_{25} \hat{s}_{26} \hat{s}_{36} & -\hat{s}_{15} \hat{s}_{16} \hat{s}_{26} - c_{15} \hat{s}_{16} \hat{s}_{26} & \hat{s}_{16} \\
    -c_{14} \hat{s}_{24} \hat{s}_{34} \hat{s}_{35} \hat{s}_{36} + c_{14} \hat{s}_{24} \hat{s}_{34} \hat{s}_{35} \hat{s}_{36} & 0
\end{pmatrix},$$  

(20)

where $c_{ij} \equiv \cos \theta_{ij}$ and $s_{ij} \equiv e^{i\delta_{ij}} \sin \theta_{ij}$ with $\theta_{ij}$ and $\delta_{ij}$ (for $1 \leq i < j \leq 6$) being rotation angles and phase angles, respectively. One can see that $V_0$ is just the standard parametrization of the unitary neutrino mixing matrix (up to some proper phase rearrangements) [18], and thus non-vanishing $A$ signifies the non-unitarity of $V$. One can also see that $A$ and $R$ involve the same parameters: nine rotation angles and nine phase angles $^2$. If all of them

$^2$Note that none of the phases of $R$ (or $A$) can be rotated away by redefining the phases of three charged-lepton fields, because such a phase redefinition will also affect the phases of $A$ (or $R$), as one can easily see from Eq. (8).
are switched off, we shall be left with $R = 0$ and $A = 1$. In view of the fact that the unitarity violation of $V$ must be very small effects (at most at the percent level as constrained by current experimental data on neutrino oscillations, rare lepton-flavor-violating or lepton-number-violating processes and precision electroweak tests [19]), one may treat $A$ as a perturbation to $V_0$. The smallness of $\theta_{ij}$ (for $i = 1, 2, 3$ and $j = 4, 5, 6$) allows us to make the following excellent approximations:

$$\hat{R} \approx 0$$

and leptogenesis. In this case, Eq. (9) is simplified to

$$\begin{align*}
0 &= \frac{1}{2} \left( s_{14}^2 + s_{15}^2 + s_{16}^2 \right) + \mathcal{O}(s_{ij}^4), \\
0 &= \frac{1}{2} \left( s_{24}^2 + s_{25}^2 + s_{26}^2 \right) + \mathcal{O}(s_{ij}^4), \\
0 &= \frac{1}{2} \left( s_{34}^2 + s_{35}^2 + s_{36}^2 \right) + \mathcal{O}(s_{ij}^4).
\end{align*}$$

with $s_{ij} \equiv \sin \theta_{ij}$ being real. Note that the approximation made in Eq. (15) is equivalent to $A \approx 1$, leading to unitary $V$ and $U$. One may therefore take $V \approx V_0$ when applying the approximate seesaw relation in Eq. (2) or (16) to the phenomenology of neutrino mixing and leptogenesis. In this case, Eq. (9) is simplified to

$$V_0 \bar{M}_\nu V_0^T \approx -R \bar{M}_N R^T. \quad (22)$$

The total number of free parameters in $\bar{M}_\nu, \bar{M}_N, V$ (or $V_0$) and $R$ is thirty (six masses, twelve mixing angles and twelve CP-violating phases). But either Eq. (9) or Eq. (22) can give twelve real constraint conditions. Hence we are left with eighteen independent parameters in the type-I seesaw mechanism.

Given the approximate expression of $R$ in Eq. (21), it is straightforward to obtain

$$\text{Im} \left( R \bar{M}_N R^T \right)_{ij} = -M_1 s_{i4} s_{j4} \sin (\delta_{i4} + \delta_{j4}) - M_2 s_{i5} s_{j5} \sin (\delta_{i5} + \delta_{j5}) - M_3 s_{i6} s_{j6} \sin (\delta_{i6} + \delta_{j6}), \quad (23)$$

where $1 \leq i < j \leq 3$. In comparison, Eqs. (4) and (18) tell us that the CP-violating asymmetries $\varepsilon_i$ (for $i = 1, 2, 3$) in unflavored leptogenesis are associated with

$$\text{Im} \left( R^i R \right)_{12} = \sum_{i=1}^{3} s_{i4} s_{i5} \sin (\delta_{i4} - \delta_{i5}) ,$$

$$\text{Im} \left( R^i R \right)_{13} = \sum_{i=1}^{3} s_{i4} s_{i6} \sin (\delta_{i4} - \delta_{i6}) ,$$

$$\text{Im} \left( R^i R \right)_{23} = \sum_{i=1}^{3} s_{i5} s_{i6} \sin (\delta_{i5} - \delta_{i6}). \quad (24)$$

We see that there are in general nine independent phase combinations in Eq. (23), while there are only six independent phase combinations in Eq. (24). It is possible to acquire $\text{Im}(R \bar{M}_N R^T) = 0$ by fine-tuning the free parameters in Eq. (23), such that $\text{Im}(V_0 \bar{M}_\nu V_0^T) \approx 0$. 

6
The same conclusion as obtained above is true for \( \alpha \) and \( F \) where the loop function \( R \) phase combinations of an extremely special case means nothing but a very special correlation between one may argue that flavored leptogenesis is linked to the neutrino mixing matrix \( V \) holds (i.e., the neutrino mixing matrix \( V \) can take place. To achieve a direct connection between the CP-violating phases of \( V \) and the CP-violating asymmetries \( \varepsilon_i \), one should switch off as many phases of \( R \) as possible. Such a treatment can be realized in some specific type-I seesaw models [20], in which the texture of \( Y_\nu \) (or \( M_D \)) might get constrained from a certain flavor symmetry in the basis of \( M_R = \hat{M}_N \). But our general conclusion is that there is only indirect connection between unflavored leptogenesis and low-energy observables.

\[ \text{[4]} \]

The same conclusion as obtained above is true for \textit{flavored} leptogenesis. When the mass of the lightest heavy Majorana neutrino is lower than about \( 10^{12} \text{ GeV} \), flavor-dependent effects matter in leptogenesis [21] and have to be carefully handled [22]. In this case, the CP-violating asymmetries \( \varepsilon_{i\alpha} \) between \( N_i \rightarrow l_\alpha + H^c \) and \( N_i \rightarrow l_\alpha^c + H \) decays (for \( i = 1, 2, 3 \) and \( \alpha = e, \mu, \tau \)) depend on the phases of \( M_D \) (or \( Y_\nu \)) in the following way [23]:

\[
\varepsilon_{i\alpha} = \frac{1}{8\pi v^2} \sum_{j \neq i} \left\{ \mathcal{F}(x_{ij}) \frac{\text{Im} \left[ \left( M_D^\dagger M_D \right)_{ij} (M_D^*)_{\alpha i} (M_D)_{\alpha j} \right]}{|(M_D)_{\alpha i}|^2} + \frac{1}{1 - x_{ij}} \frac{\text{Im} \left[ \left( M_D^\dagger M_D \right)_{ji} (M_D^*)_{\alpha j} (M_D)_{\alpha i} \right]}{|(M_D)_{\alpha i}|^2} \right\},
\]

(25)

where the loop function \( \mathcal{F}(x_{ij}) \) with \( x_{ij} \equiv M_j^2/M_i^2 \) has been given below Eq. (4). Taking account of \( M_D \approx R\hat{M}_N \), we find

\[
\text{Im} \left[ \left( M_D^\dagger M_D \right)_{ij} (M_D^*)_{\alpha i} (M_D)_{\alpha j} \right] \approx M_i^2 M_j^2 \text{Im} \left[ (R^\dagger R)_{ij} R_{\alpha i}^* R_{\alpha j} \right],
\]

\[
\text{Im} \left[ \left( M_D^\dagger M_D \right)_{ji} (M_D^*)_{\alpha j} (M_D)_{\alpha i} \right] \approx M_i^2 M_j^2 \text{Im} \left[ (R^\dagger R)_{ij} R_{\alpha j}^* R_{\alpha i} \right].
\]

(26)

It has been shown in Eq. (24) that the quantities \( (R^\dagger R)_{ij} \) (for \( i \neq j \)) rely on six independent phase combinations of \( R \). On the other hand, it is easy to check that the quantities \( R_{\alpha i}^* R_{\alpha j} \) (for \( \alpha = e, \mu, \tau \) and \( i \neq j \)) depend on the same phase combinations. Hence non-vanishing \( \varepsilon_{i\alpha} \) in Eq. (25) and \( \varepsilon_i \) in Eq. (4) originate from the same source of CP violation, no matter whether there are flavor effects or not. This point keeps unchanged even if resonant leptogenesis [22] is taken into account.

If the CI parametrization in Eq. (3) is applied to the description of flavored leptogenesis, then \( V \) will show up in the expression of \( \varepsilon_{i\alpha} \). The reason is simply that the elements of \( V \) cannot cancel out in \( (M_D^\dagger M_D)_{\alpha i} (M_D)_{\alpha j} \), although they can cancel out in \( (M_D^\dagger M_D)_{ij} \). This observation has been used by a number of authors to support the argument that viable flavored leptogenesis may result from \( V \) even in the case of \( O \) being a real orthogonal matrix (see, e.g., Refs. [12–15]). Such an argument is certainly not wrong, but it is not profound either [24]. In view of Eq. (17), we find that \( O \) can be real only when nontrivial CP-violating phases in \( V \) and \( R \) delicately combine to make \( V^\dagger R \) purely imaginary. This extremely special case means nothing but a very special correlation between \( V \) and \( R \). While one may argue that flavored leptogenesis is linked to the neutrino mixing matrix \( V \) in this contrived case, one should keep in mind that both \( \varepsilon_{i\alpha} \) and the CP-violating phases of \( V \) actually originate from \( R \) and their direct connection can only be established when some
(or most) of the phase parameters of \( R \) are switched off. In general, however, “there is no correlation between successful leptogenesis and the low-energy CP phase” [24] 3.

The CI parametrization, in which the neutrino mixing matrix \( V \) and an orthogonal matrix \( O \) are unjustifiably assumed to be independent of each other, has often been applied to the phenomenology of neutrino mixing and leptogenesis in the type-I seesaw mechanism. In the present work, we have clarified the physical meaning of \( O \) by establishing a relationship between \( O \) and the observable quantities in a generic type-I seesaw model without any special assumptions. We find that \( O \) depends not only on \( V \) but also on \( R \), the matrix responsible for the charged-current interactions of heavy Majorana neutrinos. The CP-violating phases of \( R \) govern the strength of CP violation at low energies and that in leptogenesis. We have examined the dependence of unflavored or flavored leptogenesis on \( R \) and analyzed the correlation between \( R \) and \( V \). Our general conclusion is that both unflavored leptogenesis and flavored leptogenesis have no direct connection with low-energy CP violation.

Let us finally give some remarks on \( R \), which makes more sense than \( O \) in the analysis of leptogenesis. If the type-I seesaw mechanism could be realized at the TeV scale, it might be possible to measure or constrain the mixing angles of \( R \) at the Large Hadron Collider and probe the CP-violating phases of \( R \) at a neutrino factory [25]. Because non-vanishing \( R \) is a clean signature of the unitarity violation of \( V \), it can actually lead to rich phenomenology of lepton-flavor-violating and lepton-number-violating processes. In particular, \( R \) bridges a gap between high-energy neutrino physics (e.g., heavy neutrino decays and leptogenesis) and low-energy neutrino physics (e.g., neutrino mixing and neutrino oscillations).

The author would like to thank S. Zhou for many useful discussions. This work was supported in part by the National Natural Science Foundation of China under grant No. 10425522 and No. 10875131.

---

3This conclusion was drawn in Ref. [24] from a very detailed analysis of the sensitivity of leptogenesis to the neutrino mixing matrix \( V \) by using the CI parametrization and allowing the elements of \( O \) to take arbitrary values in the parameter space. Here we arrive at the same conclusion by clarifying the physical meaning of \( O \) in an analytic way.
