Random moments for the new eigenfunctions of point scatterers on rectangular flat tori

Thomas Letendre∗ Henrik Ueberschär†

March 3, 2021

Abstract

We define a random model for the moments of the new eigenfunctions of a point scatterer on a 2-dimensional rectangular flat torus. In the deterministic setting, Šeba conjectured these moments to be asymptotically Gaussian, in the semi-classical limit. This conjecture was disproved by Kurlberg–Ueberschär on Diophantine tori. In our model, we describe the accumulation points in distribution of the randomized moments, in the semi-classical limit. We prove that asymptotic Gaussianity holds if and only if some function, modeling the multiplicities of the Laplace eigenfunctions, diverges to $+\infty$.

Keywords: Point scatterer, Poisson point process, Quantum chaos, Random wave model.

1 Introduction

1.1 Background

Let \((M, g)\) be a closed Riemannian manifold. A classical dynamical system on \(M\) is given by a Hamiltonian vector field on the associated phase space \(T^*M\). In this classical description, one tries to understand the flow of the vector field under study. Given such a classical system, it is possible to define a corresponding quantum dynamical system, which is an unbounded self-adjoint operator on \(L^2(M)\), the space of square integrable functions on \(M\). In the quantum description, one is interested in the spectrum of this operator and the properties of its eigenfunctions. A typical example of quantum system is the Laplace–Beltrami operator \(\Delta\) on \(M\), which is the quantum version of the geodesic vector field on \(T^*M\).

Quantum chaos is concerned with the asymptotic behavior, in the semi-classical limit, of the eigenfunctions of quantum systems whose classical counterpart is chaotic. The term semi-classical limit means that we consider eigenfunctions in the regime where the associated eigenvalues tend to infinity. In this regime, one expects features of the classical dynamics to emerge in the properties of the eigenfunctions. An important idea in this field is Berry’s Random Wave Conjecture (see [2]), which suggests that the eigenfunctions of quantum chaotic systems should behave like a random superposition of plane waves. Much effort has been made in recent years to develop a rigorous mathematical formulation for this conjecture and to prove its validity for various types of systems (see [1] and [7], for example). Let us mention that, after the present paper was written, Louis Gass proved that Berry’s Conjecture holds almost surely for Gaussian Random Waves on \(M\), that is for random linear combinations of Laplace eigenfunctions with Gaussian coefficients. His result is valid for both band-limited and monochromatic random waves. For more details, we refer the interested reader to his beautiful paper [5].

A weak form of Berry’s Conjecture states that, for a quantum chaotic system, the value distribution of an \(L^2\)-normalized eigenfunction should converge to a standard Gaussian in the semi-classical limit. By this we mean that, if \(\phi_\lambda\) denotes a normalized eigenfunction associated with the eigenvalue \(\lambda\) and \(X\) is a uniformly distributed point in \(M\), then the random variable \(\phi_\lambda(X)\) converges in distribution toward a standard Gaussian variable as \(\lambda \to +\infty\). In the same spirit, for any \(p \in \mathbb{N}\), the \(p\)-th central moment \(\int_M \phi_\lambda(x)^p \, dx\) of this random variable ought to converge to the corresponding moment of the standard Gaussian distribution as \(\lambda \to +\infty\). Here the integral is taken with respect to the normalized volume measure \(dx\) induced by the Riemannian metric \(g\). In this paper, we are concerned with this question of the asymptotic Gaussianity of the moments of normalized eigenfunctions for a model system: a point scatterer on a flat rectangular torus. Note that the simplest example of quantum chaotic system is the Laplacian on a surface of negative curvature. However, even for hyperbolic surfaces, the eigenfunctions of \(\Delta\) are not explicit enough to compute with, and thus do not provide a good model system for this problem.

In the following, we consider the Laplacian perturbed by a Dirac mass on a flat rectangular torus. This kind of operator is usually referred to as a point scatterer. The underlying classical system is a billiard on the torus, with an obstacle at the point where we put the Dirac mass. Its dynamics is close to integrable, since only a negligible part of the trajectories is affected by the obstacle. However, the eigenfunctions of the point scatterer may display features typical of quantum chaotic systems, depending on the shape of the torus. For example, it is known that point scatterers on the square torus are quantum ergodic [10], while on Diophantine tori their semi-classical measures are scarred along a finite number of directions in phase space [11]. The eigenfunctions of these point scatterers being reasonably explicit, they are good model systems to investigate quantum chaos.

Point scatterers were first introduced by Petr Šeba [17], who formulated several conjectures concerning the statistical properties of their spectra and the associated eigenfunctions. Since then, they have become a popular model to investigate the transition between chaotic and integrable quantum systems and have been studied in numerous papers [10, 11, 12, 15, 19, 20, 21]. In particular, Šeba carried out a numerical investigation of the value distribution of the eigenfunctions on irrational tori, which seemed to suggest that it converged to a Gaussian in the semi-classical limit. Later, Keating, Marklof and Winn [8] argued that this value distribution ought to be non-Gaussian, by comparing this problem with a similar one for quantum star graphs. To the
best of our knowledge, the only rigorous result in this direction was obtained by Kurlberg and Ueberschär. In [12], they proved that the fourth moment of the eigenfunctions of a point scatterer on a Diophantine torus cannot converge to 3, that is the fourth moment of the standard Gaussian. On the square torus, the asymptotics for general moments of the eigenfunctions for point scatterers seem difficult to obtain. This problem is already very hard in the case of Laplace eigenfunctions, where Bombieri and Bourgain managed to prove the asymptotic Gaussianity of the moments (cf. Thm. 14, Rem. 15 and Thm. 17 in [4]). A generalization of their methods to point scatterers has so far proved unsuccessful.

The purpose of the present article is to introduce a probabilistic model for the moments of the eigenfunctions of a point scatterer on a rectangular flat torus, which allows to compute the semiclassical limit of these moments. Our model and the results we obtain are described in Sect. 1.2 below. One of the key ideas in the definition of this random model is to replace the sequence of distinct Laplace eigenvalues on the ambient torus by the values of a Poisson point process. This idea originates in the paper [3] by Berry and Tabor, in which they conjectured that these eigenvalues should behave like a Poisson point process. More precisely, they studied the empirical distribution of the spacings between consecutive Laplace eigenvalues, seen as a statistical series. They argued that it should converge weakly toward an exponential distribution, which is what we expect for a Poissonian sequence. See the survey [14] for more details on this Berry–Tabor Conjecture.

1.2 Random model and main results

Let us now describe the random model we are interested in and state our main results. We consider a point scatterer on a 2-dimensional rectangular flat torus of unit area $\mathbb{T}_\alpha = \mathbb{R}^2 / (\alpha \mathbb{Z} \oplus \alpha^{-1} \mathbb{Z})$, where $\alpha > 0$. A point scatterer is a self-adjoint unbounded operator on $L^2(\mathbb{T}_\alpha)$ that can be intuitively thought of as ‘$\Delta + \delta_0$’, where $\Delta$ is the usual Laplacian and $\delta_0$ is a Dirac potential, say at $0 \in \mathbb{T}_\alpha$. More details about the ambient space we consider and the definition of this operator are given in Sect. 2.1 below.

Non-zero eigenvalues of $\Delta$ remain eigenvalues of the point scatterer. In addition to these “old” eigenvalues, the point scatterer admits a sequence of “new” simple real eigenvalues. Let $\tau \in \mathbb{R}$ denote one of these new eigenvalues. An eigenfunction of the point scatterer associated with $\tau$ is:

$$G_\tau : x \mapsto -\frac{1}{\tau} + \sum_{k \geq 1} \frac{1}{\lambda_k - \tau} \sum_{\xi \in \Lambda_k} e^{2\pi i \langle \xi, x \rangle},$$

(1.1)

where $\langle \cdot, \cdot \rangle$ is the canonical Euclidean inner product in $\mathbb{R}^2$, $(\lambda_k)_{k \geq 1}$ is the sequence of distinct positive eigenvalues of $\Delta$ and, for each $k \geq 1$, $\Lambda_k = \frac{1}{2\pi} \mathbb{Z}^2 \cap (\alpha^{-1} \mathbb{Z} \oplus \mathbb{Z}) \subset \mathbb{R}^2$ is the set of wave vectors associated with $\lambda_k$. Note that $\Lambda_k$ is a finite set which is invariant under reflection with respect to the coordinate axes. Hence the function $G_\tau$ is well-defined and real-valued.

Since $\mathbb{T}_\alpha$ has unit area, $(\mathbb{T}_\alpha, dx)$ is a probability space, where $dx$ stands for the Lebesgue measure inherited from $\mathbb{R}^2$. We denote by $X$ a uniform random variable in $\mathbb{T}_\alpha$ (i.e. the distribution of $X$ equals $dx$). We are interested in the central moments of the random variable $G_\tau(X)$. Its expectation is $\int_{\mathbb{T}_\alpha} G_\tau(x) \, dx = -\frac{1}{\tau}$. Denoting by $f_\tau = G_\tau + \frac{1}{\tau}$ and by

$$M_p^\tau = \int_{\mathbb{T}_\alpha} f_\tau(x)^p \, dx,$$

(1.2)

the $p$-th normalized central moment of $G_\tau(X)$ equals $(M_2^\tau)^{-\frac{p}{2}} M_p^\tau$. It was conjectured by Šeba [17] that, for every integer $p \geq 1$, this quantity converges as $\tau \to +\infty$ to $\mu_p$, the $p$-th moment of a standard Gaussian variable. In the following, we refer to $M_p^\tau$ as the $p$-th moment of $f_\tau$. In this paper, we do not tackle this problem of computing the asymptotics of the deterministic normalized moments $(M_2^\tau)^{-\frac{p}{2}} M_p^\tau$. Instead, we consider the same question for a random model.

Remark 1.1. We do not use the classical notation $E[f_\tau(X)^p]$ for the $p$-th moment of $f_\tau$ and use integral notations instead. The reason is that we wish to avoid any confusion between the randomness coming from the choice of the random point $X$ (that we do not consider, except in the definition of $M_p^\tau$ above) and the randomness coming from the random model introduced below.
As one can see from the definition, for any \( \tau \), the function \( f_\tau \) only depends on the positive spectrum \((\lambda_k)_{k \geq 1}\) of the usual Laplacian on \( T_\alpha \), and the associated wave vectors sets \((\Lambda_k)_{k \geq 1}\). In view of the Berry–Tabor Conjecture [3], a natural random model for the new centered eigenfunction \( f_\tau \) would be the following.

1. Choose \((\lambda_k)_{k \geq 1}\) to be the values of a Poisson point process on \([0, +\infty)\).

2. For each \( k \geq 1 \), define \( \Lambda_k \cap [0, +\infty)^2 \) as a random subset of \( \frac{\sqrt{\pi}}{28} S^1 \cap [0, +\infty)^2 \), and define \( \Lambda_k \) as the closure of this set under reflection with respect to the coordinate axes. For example, one could choose the directions of the points of \( \Lambda_k \cap [0, +\infty)^2 \) to be globally independent, independent of \((\lambda_k)_{k \geq 1}\), and uniformly distributed in \([0, \frac{\pi}{2}]\).

3. Define \( f_\tau : x \mapsto \sum_{k \geq 1} \frac{1}{\lambda_k - \gamma} \sum_{\xi \in \Lambda_k} e^{2\pi i \langle \xi, x \rangle} \).

Then, one could consider the normalized moments of this random \( f_\tau \) and study their asymptotics as \( \tau \to +\infty \). Of course, one would need to make reasonable choices for the intensity of the Poisson point process \((\lambda_k)_{k \geq 1}\) and for the multiplicities of these mock eigenvalues (i.e. the cardinalities of the random sets \((\Lambda_k)_{k \geq 1}\)).

Unfortunately, this model is a bit too naive and has at least one major flaw. In the deterministic case, \((\Lambda_k)_{k \geq 1}\) are subsets of \( a^{-1}Z \oplus aZ \), which ensures that the complex exponentials appearing in the definition of \( f_\tau \) (resp. \( G_\tau \)) have the right periodicity and define functions on the torus \( T_\alpha \). In the model we just described, no such condition is required of the random sets \((\Lambda_k)_{k \geq 1}\). In particular, the complex exponentials appearing in the definition of the randomized \( f_\tau \) do not define functions on \( T_\alpha \). Thus, \( f_\tau \) is ill-defined as a function from \( T_\alpha \) to \( \mathbb{R} \), and it makes no sense to consider its moments.

**Remark 1.2.** One might be tempted to save this model by working in a rectangle of \( \mathbb{R}^2 \) instead of a torus. This allows to make sense of the randomized \( f_\tau \) and its moments. However, when computing \( M^p_\tau \) in the deterministic case, a lot of terms vanish because of the periodicity of the complex exponentials. These cancellations do not take place for the moments of the randomized \( f_\tau \). Because of this, their computation quickly becomes impractical.

The random model we consider in this paper is built using the same basic ideas as the naive model we just discussed. In order to make these ideas work, we need to randomize the problem in steps. In the remainder of this section, we describe these steps and how they lead to our main result (Thm. 1.22 below). We discuss the various assumptions of our model in Sect. 1.3.

**Step 1: Deterministic expression of the moments.** We first consider the moments of the deterministic functions \( f_\tau \). In this first step, no randomness is involved. We still denote by \((\lambda_k)_{k \geq 0}\) the increasing sequence of distinct eigenvalues of \( \Delta \) on \( T_\alpha \), and by \((\Lambda_k)_{k \geq 0}\) the associated wave vectors sets. For any \( \tau \in \mathbb{R} \setminus \text{Sp}(\Delta) \), we define as above \( f_\tau = G_\tau + \frac{1}{\tau} \), where \( G_\tau \) is the function defined by Eq. (1.1). For any \( p \in \mathbb{N}^* \), we denote by \( M^p_\tau \) the \( p \)-th moment of \( f_\tau \), as in Eq. (1.2). Note that we denote by \( \mathbb{N} \) the set of non-negative integers and by \( \mathbb{N}^* = \mathbb{N} \setminus \{0\} \), the set of positive integers. Let us introduce some additional notations.

**Definition 1.3.** We denote by \( \ell_0 = \{ (a_k)_{k \geq 1} \in \mathbb{N}^{\mathbb{N}^*} \mid \sum_{k \geq 1} a_k < +\infty \} \) the set of sequences of non-negative integers with finite support, indexed by \( \mathbb{N}^* \). For any \( a = (a_k)_{k \geq 1} \in \ell_0 \), we denote by \( a! = \prod_{k \geq 1} a_k! \) and by \( |a| = \sum_{k \geq 1} a_k \).

**Definition 1.4.** Let \( a = (a_k)_{k \geq 1} \in \ell_0 \), we denote by:

\[
N_a = \text{card} \left\{ (\xi_{k,l})_{k \geq 1; 1 \leq l \leq a_k} \in \prod_{k \geq 1} (\Lambda_k)^{a_k} \left| \sum_{k \geq 1} \sum_{l=1}^{a_k} \xi_{k,l} = 0 \right. \right\}.
\]

Here, we use the convention that \((\Lambda_k)^0 = \{0\}\) and \(\prod_{k \geq 1} (\Lambda_k)^{a_k}\) is canonically identified with the finite product \(\prod_{\{k \geq 1 \mid a_k \neq 0\}} (\Lambda_k)^{a_k}\). Thus, if \(0\) denotes the zero sequence, we have \(N_0 = 1\).
The coefficient $N_a$ counts the number of $|a|$-tuples of lattice points in $\alpha^{-1}\mathbb{Z} \oplus \alpha\mathbb{Z}$ summing up to 0, with some additional constraints. In particular, the sequence $(N_a)_{a \in \ell_0}$ heavily depends on the number-theoretical properties of the aspect ratio $\alpha^2$. With these notations in mind, we have the following deterministic expression of the moments, which is proved in Sect. 2.2.

**Proposition 1.5.** Let $(\lambda_k)_{k \geq 1}$ denote the increasing sequence of distinct positive Laplace eigenvalues on $T_\alpha$. Let $p \in \mathbb{N}^*$, let $\tau \in \mathbb{R} \setminus \text{Sp}(\Delta)$ and let $M_p^\tau$ be defined by Eq. (1.2). We have:

$$M_p^\tau = p! \sum_{a \in \ell_0; |a| = p} \frac{N_a}{a!} \prod_{k \geq 1} \left( \frac{1}{\lambda_k - \tau} \right)^{a_k}.$$  

(1.3)

For any $p \in \mathbb{N}^*$ and $\tau \in \mathbb{R} \setminus \text{Sp}(\Delta)$, the expression of $M_p^\tau$ only depends on the sequence $(\lambda_k)_{k \geq 1}$ of positive eigenvalues of $\Delta$, and on the wave vectors sets $(\Lambda_k)_{k \geq 1}$ through the coefficients $(N_a)_{a \in \ell_0}$. It is this expression that we randomize in the subsequent steps. In particular, we define a random model for the moments $M_p^\tau$, but these randomized moments are not defined as the moments of some random function on $\mathbb{T}_\alpha$.

**Step 2: randomization of the wave vectors.** In this second step, we start to introduce some randomness by randomizing the wave vectors sets $(\Lambda_k)_{k \geq 1}$. We assume that we are given an increasing sequence $(\lambda_k)_{k \geq 1}$ of positive numbers and a sequence $(m_k)_{k \geq 1}$ of positive integers. For any $k \in \mathbb{N}^*$, we want to define $\Lambda_k$ as a random finite subset of $\frac{\mathbb{Z}^2}{\mathbb{Z} \Lambda} \subset \mathbb{R}^2$, which is invariant by reflection with respect to the coordinate axes, and such that card $(\Lambda_k \cap [0, +\infty)^2) = m_k$. This amounts to choosing random directions for the $m_k$ elements of $\Lambda_k \cap [0, +\infty)^2$.

Here, the sequence $(\lambda_k)_{k \geq 1}$ can be the positive spectrum of the Laplacian on some rectangular flat torus, or a realization of a Poisson point process on $[0, +\infty)$, or anything else. Similarly, the sequence $(m_k)_{k \geq 1}$ can be the one given by the deterministic wave vectors sets we want to model, or not.

**Definition 1.6.** Let $\eta$ denote the product of the uniform probability measures on $[0, \frac{\pi}{2}]^{\mathbb{N}^* \times \mathbb{N}^*}$, that is the distribution of a sequence of independent uniform variables in $[0, \frac{\pi}{2}]$, indexed by $\mathbb{N}^* \times \mathbb{N}^*$.

**Definition 1.7.** Let $(\lambda_k)_{k \geq 1}$ be an increasing sequence of positive numbers, let $(m_k)_{k \geq 1}$ be a sequence of positive integers and let $(\theta_{k,j})_{k,j \geq 1}$ be a sequence of random variables in $[0, \frac{\pi}{2}]$ whose distribution is absolutely continuous with respect to $\eta$. Then, for any $k \geq 1$, we set:

$$\Lambda_k = \frac{\sqrt{\lambda_k}}{2\pi} \left\{ \zeta^{(1)}(\theta_{k,j}) \mid 1 \leq j \leq m_k, 1 \leq i \leq 4 \right\},$$

where we denoted, for every $\theta \in [0, \frac{\pi}{2}]$:

$$\zeta^{(1)}(\theta) = (\cos(\theta), \sin(-\theta)) = -\zeta^{(3)}(\theta) \quad \text{and} \quad \zeta^{(2)}(\theta) = (-\cos(\theta), \sin(\theta)) = -\zeta^{(4)}(\theta).$$

Working with the randomized $(\Lambda_k)_{k \geq 1}$ introduced in Def. 1.7, we define a random sequence $(N_a)_{a \in \ell_0}$ as in Def. 1.4. Similarly, for any $p \in \mathbb{N}^*$ and $\tau \in \mathbb{R} \setminus \{\lambda_k \mid k \geq 1\}$, we define the randomized moment $M_p^\tau$ by the formula appearing in Prop. 1.5, see Eq. (1.3). Our choice of probability distribution allows us to derive an almost sure expression for $(N_a)_{a \in \ell_0}$, see Lem. 3.3.

This expression is purely combinatorial and only depends on the sequence $(m_k)_{k \geq 1}$. In particular, there is no longer any number theory involved in the problem at this stage. From the almost sure expression of $(N_a)_{a \in \ell_0}$, we deduce an almost sure expression of the randomized moments $M_p^\tau$. In order to give a precise statement, we will need the following definitions.

**Definition 1.8.** Let $p \in \mathbb{N}$, we denote by $\mathcal{P}(p) = \left\{ (\alpha_k)_{k \geq 1} \in \ell_0 \mid \sum_{k \geq 1} k \alpha_k = p \right\}$ the set of partitions of $p$.

**Definition 1.9.** Let $p \in \mathbb{N}^*$, we denote by $P_p$ and $Q_p$ the following polynomials in $p$ variables:

$$P_p(X_1, \ldots, X_p) = \sum_{\alpha \in \mathcal{P}(p)} (-1)^{p - |\alpha|} |\alpha|! \prod_{q \geq 1} (X_q)^{\alpha_q},$$

$$Q_p(X_1, \ldots, X_p) = \sum_{\alpha \in \mathcal{P}(p)} \frac{(-1)^{p - |\alpha|}}{|\alpha|} |\alpha|! \prod_{q \geq 1} (X_q/q!)^{\alpha_q}. $$

5
Remark 1.10. The set $\mathcal{P}(p)$ is finite. Moreover, if $\alpha = (\alpha_q)_{q \geq 1} \in \mathcal{P}(p)$, then for all $q > p$, we have $\alpha_q = 0$. Hence, we can index the products appearing in Def. 1.9 by $1 \leq q \leq p$ instead of $q \geq 1$. Thus, $P_p$ and $Q_p$ are indeed polynomials and their total degree is at most $p$. In fact, for all $p \geq 1$, the total degree of $P_p$ and $Q_p$ equals $p$.

**Definition 1.11.** For any $p \in \mathbb{N}^*$, we denote by $A_p = Q_p \left(1, \frac{1}{\pi^2}, \ldots, \frac{1}{\pi^p}\right)$.

**Definition 1.12.** Let $(\lambda_k)_{k \geq 1}$ be an increasing sequence of positive numbers and let $(m_k)_{k \geq 1}$ be a sequence of non-negative numbers. For any $p \in \mathbb{N}^*$ and $\tau \in \mathbb{R}$, we denote by $S_p^\tau$ the spectral sum:

$$S_p^\tau = \sum_{k \geq 1} \frac{m_k}{(\lambda_k - \tau)^{2p}},$$

where the sum makes sense in $[0, +\infty]$ as a sum of non-negative (possibly infinite) terms.

**Proposition 1.13.** Let $(\lambda_k)_{k \geq 1}$ be an increasing sequence of positive numbers, let $(m_k)_{k \geq 1}$ be a sequence of positive integers. Let $(\Lambda_k)_{k \geq 1}$ be defined by Def. 1.7 and let the corresponding randomized moments $(M^p_k)_{p \geq 1}$ be defined by Eq. (1.3). Then, almost surely, the following holds for all $p \in \mathbb{N}^*$ and $\tau \in \mathbb{R} \setminus \{\lambda_k | k \geq 1\}$.

1. We have $M^{2p-1} = 0$.

2. If $S^\tau_q < +\infty$ for all $q \in \{1, \ldots, p\}$, then we have:

$$M^p_{\tau} = \frac{(2p)!}{p!} P_p(2A_1S^1, \ldots, 2A_pS^p),$$

where the polynomial $P_p$ and the coefficients $A_1, \ldots, A_p$ are defined respectively by Def. 1.9 and 1.11. In particular, $M^{2p} < +\infty$.

Prop. 1.13 shows that, in our model, the odd moments vanish almost surely. This is consistent with the idea that the moments should be asymptotically those of a standard Gaussian. In the following, we only consider even moments. Almost surely, the moment of order $2p$ is the value of some fixed polynomial in $p$ variables, whose coefficients only depend on $p$, evaluated at $(S^1, \ldots, S^p)$. Thus, $M^{2p}$ only depends on $\tau$, $(\lambda_k)_{k \geq 1}$ and $(m_k)_{k \geq 1}$, and this only through the spectral sums $(S^\tau_q)_{1 \leq q \leq p}$.

**Remark 1.14.** In the case of the square torus $(\alpha = 1)$, the deterministic wave vectors sets $(\Lambda_k)_{k \geq 1}$ are also invariant under $(x_1, x_2) \mapsto (x_2, x_1)$. In Sect. 3.1.2, we define a variation on our random model such that the randomized $(\Lambda_k)_{k \geq 1}$ also have this additional symmetry (see Def. 3.6). It turns out that the previous results can be adapted to this alternative model. In particular, the conclusion of Prop. 1.13 remains valid.

**Step 3: randomization of the spectrum of the Laplacian.** In this final step, we start from the expressions of the moments derived in Prop. 1.13, and we randomize the sequences $(\lambda_k)_{k \geq 1}$ and $(m_k)_{k \geq 1}$ in these expressions. Inspired by the Berry–Tabor Conjecture, we replace $(\lambda_k)_{k \geq 1}$ by the values of a Poisson point process on $[0, +\infty)$ (see Sect. A for a quick reminder about these processes). Since it is meant to model the spectrum of the Laplacian on some $T^2$, we tune the intensity of this point process so that it satisfies the Weyl Law in the mean and to leading order. Let us recall this classical result.

**Theorem 1.15 (Weyl Law).** On $T^2$, let $N(\lambda)$ denote the number of Laplace eigenvalues smaller than or equal to $\lambda$, counted with multiplicities. Then, we have $N(\lambda) = \frac{\lambda}{4\pi^2} + O(\sqrt{\lambda})$ as $\lambda \to +\infty$.

Note that, with the random model for the wave vectors introduced in Step 2, what plays the role of the multiplicity of $\lambda_k$ is almost surely $4m_k$. Hence, the intensity of our Poisson process must somehow be related to the sequence $(m_k)_{k \geq 1}$.

**Definition 1.16.** Let $m : [0, +\infty) \to [1, +\infty)$ be a function of class $C^1$. We say that $m$ is a multiplicity function if there exists $\beta > 0$ such that $m(\ell) = O(\ell^{-\beta})$ as $\ell \to +\infty$. 

Definition 1.17. Let \( m \) be a multiplicity function, we denote by \( \nu_m \) the measure on \([0, +\infty)\) admitting the density \((16\pi m)^{-1}\) with respect to the Lebesgue measure.

Definition 1.18. Let \( m \) be a multiplicity function. We define the random sequence \((\lambda_k)_{k \geq 1}\) as the increasing sequence of the values of a Poisson point process on \([0, +\infty)\) of intensity \(\nu_m\). Moreover, for all \( k \geq 1 \), we set \( m_k = m(\lambda_k) \).

It is a classical fact that the sequence \((\lambda_k)_{k \geq 1}\) defined by Def. 1.18 is almost surely a sequence of positive numbers that diverges to \(+\infty\) as \( k \to +\infty \). For the reader’s convenience, we included a proof of this fact in App. A, see Lem. A.2. Note that, as a consequence of Def. 1.16 and 1.18, almost surely the sequence \((m_k)_{k \geq 1}\) is no longer integer-valued at this stage. We will comment further on this issue in Sect. 1.3, where we discuss the features of our random model.

Thanks to Prop. 1.13.1, we are now only interested in moments of even order. Let \( \mu_p = \frac{(2p)!}{4^p p!} \) and \( \mu_{2p+1} = 0 \).

Theorem 1.22. Let \( m \) be a multiplicity function and let \( \tau \in \mathbb{R} \). We sample random sequences \((\lambda_k)_{k \geq 1}\) and \((m_k)_{k \geq 1}\) as in Def. 1.18. Then, for all \( p \in \mathbb{N}^* \), we define the randomized spectral sum \( S_p^\tau \) as in Def. 1.12 and the randomized even moment \( M_p^\tau \) by Eq. (1.4). It turns out that these random variables are almost surely well-defined. The proof of the following result is given at the end of Sect. 3.2.

Lemma 1.19. Let \( \tau \in \mathbb{R} \). Let \( m \) be a multiplicity function, let \((\lambda_k)_{k \geq 1}\) be the associated randomized spectrum, and let \( m_k = m(\lambda_k) \) for all \( k \geq 1 \). Then, almost surely, for all \( p \geq 1 \), the spectral sum \( S_p^\tau \) is finite, and the randomized moment \( M_p^\tau \) is well-defined and finite.

Remark 1.20. There is a small subtlety here. If we sample the sequence \((\lambda_k)_{k \geq 1}\) once and work with the same realization for all \( \tau \in \mathbb{R} \) then, whenever \( \tau \) is equal to one of the \( \lambda_k \), the random variables \((S_p^\tau)_{p \geq 1}\) diverge and the \((M_p^\tau)_{p \geq 1}\) are ill-defined. Here, we work with a fixed \( \tau \), for which the random variables we are interested in are almost surely well-defined by Lem. 1.19. In particular, we can consider the distribution of these random variables for any \( \tau \), and study their limit in distribution as \( \tau \to +\infty \).

We can now state our main result, which describes the asymptotic joint distribution of the even normalized moments \((M_p^\tau)^{-p}M_p^\tau \) for \( p \geq 2 \), as \( \tau \to +\infty \). Note that for \( p = 1 \), for all \( \tau \in \mathbb{R} \), we have \((M_1^\tau)^{-p}M_p^\tau = 1\) deterministically.

Definition 1.21. We denote by \((\mu_p)_{p \geq 0}\) the sequence of moments of a standard real Gaussian variable. Recall that for any \( p \in \mathbb{N} \), we have \( \mu_{2p} = \frac{(2p)!}{2^{2p} p!} \) and \( \mu_{2p+1} = 0 \).

Theorem 1.22. Let \( m \) be a multiplicity function and let \((\lambda_k)_{k \geq 1}\) and \((m_k)_{k \geq 1}\) be associated random sequences as in Def. 1.18. For any \( \tau \in \mathbb{R} \), let the randomized even moments \((M_p^\tau)_{p \geq 1}\) be defined by Eq. (1.4).

For any integer \( p \geq 2 \), there exists a one-parameter family \((R_2(l), \ldots, R_p(l))_{l \in (0, +\infty)}\) of random vectors in \(\mathbb{R}^{p-1}\) such that, if \((\tau_n)_{n \geq 0}\) is a sequence of real numbers satisfying \(\tau_n \to +\infty \) and \(m(\tau_n) \to l \) as \(n \to +\infty\), then the following holds in distribution:

\[
\begin{pmatrix}
\left\langle \frac{M_p^{\tau_n}}{(M_p^{\tau_n})^{2}} \right\rangle, & \left\langle \frac{M_p^{\tau_n}}{(M_p^{\tau_n})^{p}} \right\rangle
\end{pmatrix}
\to (\mu_2 R_2(l), \ldots, \mu_{2p} R_p(l)).
\]

Moreover, the distribution of \((R_2(l), \ldots, R_p(l))\) only depends on \( p \) and \( l \) and satisfies the following.

- If \( l = +\infty \), then we have \((R_2(l), \ldots, R_p(l)) = (1, \ldots, 1)\) almost surely, so that the previous convergence holds in probability.
- If \( l \in (0, +\infty) \), then \((R_2(l), \ldots, R_p(l))\) admits a smooth density with respect to the Lebesgue measure of \(\mathbb{R}^{p-1}\).
- The random vectors \((R_2(l), \ldots, R_p(l))\) and \((R_2(l'), \ldots, R_p(l'))\) are equal in distribution if and only if \( l = l' \).

Remark 1.23. If \( 2 \leq q \leq p \) then, for any \( l \in (0, +\infty) \), the random vector \((R_2(l), \ldots, R_q(l))\) is distributed as the first \( q - 1 \) components of \((R_2(l), \ldots, R_p(l))\). In particular the distribution of \((R_2(l), \ldots, R_q(l))\) is uniquely defined and does not depend on \( p \geq q \).
Remark 1.24. The same proof as that of Thm. 1.22 shows that if $m(\tau) \xrightarrow{\tau \to +\infty} t$ then we have:

$$
\left(\frac{M^4_1}{(M^2_1)^2}, \ldots, \frac{M^{2p}}{(M^2_1)^p}\right) \xrightarrow{\tau \to +\infty} (\mu_4 R_2(l), \ldots, \mu_{2p} R_p(l))
$$

in distribution, see Sect. 3.4, and especially the proof of Lem. 3.17.

Thm. 1.22 is consistent with the deterministic result of Kurlberg and Ueberschär [12]. They proved that on Diophantine tori, the 4-th normalized moment of the new eigenfunctions of a point scatterer is bounded away from $\mu_4$ along a full-density subsequence of new eigenvalues. Our result suggests that, in the deterministic setting, the asymptotic behavior of the normalized moments of the new eigenfunctions mostly depends on the asymptotics of the multiplicities of the eigenvalues of the Laplacian.

We conclude this section by stating one last result. Let $m$ be a multiplicity function (see Def. 1.16) and let $N(\tau)$ be a multiplicity function (see Def. 1.17) of the Poisson point process $(\lambda_k)_{k \geq 1}$ so that $\mathbb{E}[N_m(\lambda)] \sim \frac{1}{\lambda}$ as $\lambda \to +\infty$, in agreement with the Weyl Law. In fact, we have a much stronger result.

**Proposition 1.25** (Random Weyl Law). Let $m$ be a multiplicity function and let $N_m$ be defined by Eq. (1.5). For all $\lambda \geq 0$, we have $\mathbb{E}[N_m(\lambda)] = 1 + \frac{1}{\lambda}$ and $\text{Var}(N_m(\lambda)) = \frac{1}{\pi} \int_0^\lambda m(t) \, dt$. Moreover, the following holds.

1. (Strong Law of Large Numbers) Almost surely $\frac{1}{\lambda} N_m(\lambda) \xrightarrow{\lambda \to +\infty} \frac{1}{4\pi}$.

2. (Central Limit Theorem) As $\lambda \to +\infty$, the random variable $\frac{N_m(\lambda) - \mathbb{E}[N_m(\lambda)]}{\sqrt{\text{Var}(N_m(\lambda))}}$ converges in distribution toward a standard real Gaussian.

Remark 1.26. In the usual Weyl Law, the error term is of order $O(\sqrt{\lambda})$. Here, the fluctuations around the leading term are of order $(\int_0^\lambda m(t) \, dt)^{\frac{3}{2}}$. Since the values of $m$ are larger than 1, this term is greater than $\sqrt{\lambda}$. On the other hand, using Def. 1.16, one can prove that this term is of order $O(\lambda^\alpha)$ for some $\alpha \in [0, 1)$. In fact, for any $\alpha \in [0, 1)$, we can build a multiplicity function $m$ such that $(\int_0^\lambda m(t) \, dt)^{\frac{3}{2}} \sim \lambda^{\frac{1+\alpha}{2}}$ as $\lambda \to +\infty$.

### 1.3 Discussion of the random model

Let us discuss the various assumptions in our model. The first thing to recall is that we defined a random model for the moments of some function $f_\tau : T_\alpha \to \mathbb{R}$, but the random moments $(M^p_\tau)$ that we study are not the moments of some randomized version of $f_\tau$. In fact, trying to define a random model for $f_\tau$, using the same ingredients as our model leads to some serious difficulties, as discussed in Sect. 1.2.

In Step 1, we compute the deterministic moments of the function $f_\tau$. As one expects, in the course of this computation, a lot of terms vanish for periodicity reasons. This is a typical feature of the problem we wish to model, and it is naturally present in our random model since we start from the deterministic expression obtained at the end of Step 1, in Prop. 1.5.

In Step 2, we assume that the sequences $(\lambda_k)_{k \geq 1}$ and $(m_k)_{k \geq 1}$ are fixed, and we randomize the directions $(\theta_{k,j})$ of the wave vectors. We only ask that the distribution of these directions admits a density with respect to some natural measure. Though this assumption does not seem very restrictive, it is enough to kill all the number-theoretic aspects of the problem. On the one hand, this is what allows us to say something about our model. But on the other hand this means...
that our model is too crude to capture any of the arithmetic subtleties of the deterministic setting. Still, the almost sure result of Prop. 1.13 is very robust, in the sense that it does not depend on the actual density of \( (\theta_{k,j}) \). This shows that there is a lot of flexibility in this random model, and we hope that it is enough for it to say something of the deterministic case.

Let us give some examples of admissible distributions for the sequence \( (\theta_{k,j})_{k,j \geq 1} \). In view of Def. 1.7, we are only interested in the distribution of the subsequence \( (\theta_{k,j})_{k \geq 1; 1 \leq j \leq m_k} \), which must admit a density with respect to the product of the Lebesgue measures. In the following examples, we describe the joint distribution of the random variables \( (\theta_{k,j})_{k,j \geq 1} \) from these, by choosing the remaining terms to be independent uniform variables in \( [0, \frac{\pi}{2}] \).

**Examples 1.27.**
1. The \( (\theta_{k,j})_{k \geq 1; 1 \leq j \leq m_k} \) are independent uniform variables in \( [0, \frac{\pi}{2}] \). The distribution of the corresponding sequence \( (\theta_{k,j})_{k,j \geq 1} \) is then \( \eta \).

2. Let us assume that \( (\lambda_k)_{k \geq 1} \) is the spectrum of \( \Delta \) on some \( \mathbb{T}_\alpha \), and that the associated wave vectors are known, up to some error. Let us say, for example, that the deterministic \( \Lambda_k \) is of the form \( \frac{\sqrt{2\pi}}{2\pi} \{ \langle \beta_{k,j} \rangle \mid 1 \leq j \leq m_k, 1 \leq i \leq 4 \} \), where we know that \( \beta_{k,j} \) belongs to some interval \( I_{k,j} \subset [0, \frac{\pi}{2}] \), for any \( k \geq 1 \) and \( j \in \{1, \ldots, m_k\} \). In this case, we can define \( (\theta_{k,j})_{k \geq 1; 1 \leq j \leq m_k} \) as a sequence of independent variables admitting a density with respect to the Lebesgue measure on \( [0, \frac{\pi}{2}] \), and such that \( \theta_{k,j} \) is supported on \( I_{k,j} \).

3. One can introduce some repulsion between the directions \( (\theta_{k,j})_{k \geq 1; 1 \leq j \leq m_k} \). A naive example is to define the density of the distribution of \( (\theta_{k,j})_{1 \leq j \leq m_k} \) with respect to the Lebesgue measure on \( [0, \frac{\pi}{2}]^{m_k} \) as:

\[
Z_k \exp \left( - \sum_{1 \leq i < j \leq m_k} \frac{1}{|\theta_{k,i} - \theta_{k,j}|^2} \right),
\]

where \( Z_k \) is some normalizing constant. Then take the product distribution over \( k \geq 1 \).

4. One can mix the previous two examples and build admissible distributions such that the \( (\theta_{k,j})_{k \geq 1; 1 \leq j \leq m_k} \) are both localized and repel one another.

Note that the density of \( (\theta_{k,j}) \) can depend on the sequences \( (\lambda_k)_{k \geq 1} \) and \( (m_k)_{k \geq 1} \). Since we obtain an almost sure result independent of this density in Prop. 1.13, there is no coupling issue when we randomize \( (\lambda_k)_{k \geq 1} \) and \( (m_k)_{k \geq 1} \) in Step 3. Note also that our assumption that \( (\theta_{k,j}) \) admits a density with respect to \( \eta \) (cf. Def. 1.6) is a little stronger than what we actually need. It is enough to assume that all the p-dimensional marginal distributions of \( (\theta_{k,j})_{k \geq 1; 1 \leq j \leq m_k} \) admit a density with respect to Lebesgue to prove Prop. 1.13 for the \( p \)-th moment.

In Step 3, we finally replace the sequence \( (\lambda_k)_{k \geq 1} \) by the values of a Poisson point process. Since we want this sequence to model the spectrum of \( \Delta \), it is natural to ask that it satisfies a version of the Weyl Law. As explained in Sect. 1.2, this means that the definitions of the intensity measure of the point process and of the sequence \( (m_k)_{k \geq 1} \) must be intertwined. We define \( m_k \) as \( m(\lambda_k) \) for all \( k \geq 1 \), where \( m : [0, +\infty) \to [1, +\infty) \) is some fixed function. That is, the mock multiplicities \( (m_k)_{k \geq 1} \) depend deterministically on the randomized spectrum \( (\lambda_k)_{k \geq 1} \). This point is fundamental in our approach. It allows us to write the randomized spectral sums \( S^p_m \) (see Def. 1.12), which are the relevant random variables to consider in this problem, as \( \sum_{k \geq 1} g_p(\lambda_k) \) for some function \( g_p \). Then we can study these quantities using Campbell’s Theorem (recalled in App. A, Thm. A.3). The same tools also show that, with our definition of \( \nu_m \) (see Def. 1.17), the sequence \( (\lambda_k)_{k \geq 1} \) satisfies a Random Weyl Law (see Prop. 1.25).

Let us now discuss our choice of the multiplicity function \( m \). One could think of taking \( m \) to be measurable and integer-valued. Instead, we ask our multiplicity functions to be regular enough (cf. Def. 1.16), in order to use some analytic tools. This part of the model is probably the one that seems less natural, because we replace a sequence of integers by the values of a smooth function evaluated at random points. In particular, generically, none of the \( m(\lambda_k)_{k \geq 1} \) is an integer. This is not an issue, because Prop. 1.13 gives an almost sure expression of \( M^p_n \), where the sequence \( (m_k)_{k \geq 1} \) only appears through the spectral sums \( (S^p_{m})_{1 \leq q \leq p} \), and the definition of these sums (Def. 1.12) makes sense as soon as the \( (m_k)_{k \geq 1} \) are non-negative. In fact, the expression of \( S^p_{m} \) hints that what
matters here is the asymptotic behavior of \((m_k)_{k \geq 1}\), or equivalently of \(m\), rather than \((m_k)_{k \geq 1}\) being integer-valued.

The precise condition we ask our multiplicity function to satisfy (cf. Def. 1.16) may seem quite arbitrary. Indeed, to the best of our understanding, it is only a technical condition that allows our proofs to work. This condition can be weakened a bit. In most of this paper, we only need \(m\) to be such that \(m(t) \to +\infty\) as \(t \to +\infty\). The only place where we need a stronger assumption is to prove the Law of Large Numbers part in Prop. 1.25. There, we need to further assume that \(m(t) = O(t^\alpha)\) as \(t \to +\infty\), for some \(\alpha < 1\).

Let us give some examples of admissible multiplicity functions. The first two examples show that defining \((m_k)_{k \geq 1}\) as \((m(\lambda_k))_{k \geq 1}\) allows us to model the average behavior of the deterministic multiplicities of the Laplace eigenvalues on some flat tori.

**Examples 1.28.**

1. On an irrational torus, that is on \(T_{\alpha}\) with \(\alpha \notin \mathbb{Q}\), the multiplicity of a generic deterministic eigenvalue of \(\Delta\) is 4. This suggests to model this case by setting \(m : t \mapsto 1\).

2. On the square torus \(T\), it is known that \(\frac{1}{k} \sum_{i=1}^{k} r_i \sim 4C_0 \ln(\lambda_k)\) as \(k \to +\infty\), where \((\lambda_k)_{k \geq 1}\) are the deterministic eigenvalues of the Laplacian, \((r_k)_{k \geq 1}\) are their multiplicities, and \(C_0\) is some explicit constant. This follows from Landau’s Theorem [13], which gives the counting asymptotics of the Laplace eigenvalues without multiplicities, and Weyl’s Law (Thm. 1.15). This suggests to model this case using the multiplicity function \(m : t \mapsto 1 + C_0 \ln(1 + t)^{\frac{1}{4}}\).

Note that \(r_k = 8\) for infinitely many \(k \geq 1\). With our definition of multiplicity function, we can only model the average behavior of the multiplicities of the deterministic Laplace eigenvalues.

3. More generally, \(t \mapsto 1 + C \ln(1 + t)^{\alpha}\) is a multiplicity function if \(C \geq 0\) and \(\alpha \geq 0\), and \(t \mapsto 1 + Ct^{\alpha}\) is a multiplicity function if \(C \geq 0\) and \(0 \leq \alpha < 1\).

We conclude this section with a last remark. In Step 1 and Step 2, the even moments \((M_r^2)_{p \geq 1}\) are positive. In Step 3, we redefine these even moments using Eq. (1.4). If the multiplicity function \(m\) is constant, equal to some integer, then a computation similar to the proof of Prop. 1.13 shows that: for all \(\tau \in \mathbb{R}\), almost surely, for all \(p \in \mathbb{N}^*, M_r^2 > 0\). Unfortunately, this kind of computation does not make sense if \(m\) is not integer-valued. For a general \(m\), it is not clear that the even randomized moments are almost surely positive. It is natural to conjecture that this is the case, but we do not know how to prove it at this point.

### 1.4 Organization of the paper

The paper is organized as follows. In Sect. 2, we study the deterministic situation. In Sect. 2.1, we describe the new eigenfunctions of point scatterers on rectangular flat tori, then, in Sect. 2.2, we study their moments. The main result of Sect. 2 is the proof of Prop. 1.5.

In Sect. 3, we introduce and study our random model. Sect. 3.1 is concerned with what we called Step 2 in the Introduction (see Sect. 1.2), that is the randomization of the wave vectors. In this section we prove Prop. 1.13, for our random model in Sect. 3.1.1 and for a variation adapted to the square torus in Sect. 3.1.2. In Sect. 3.2 we conclude the definition of our random model as in Step 3 above. Then, we study the asymptotic distribution of the spectral sums (see Def. 1.12) in Sect. 3.3 and we prove Thm. 1.22 in Sect. 3.4.

Sect. 4 is concerned with the proof of the Random Weyl Law (Prop. 1.25). App. A surveys some basic facts about Poisson point processes, including Campbell’s Theorem (Thm. A.3), which is one of the key tools in the proof of our main results. Finally, we gathered the proofs of several technical lemmas in App. B.

**Acknowledgment.** The authors thank Stéphane Nonnenmacher for his remarks and comments, that helped to improve the exposition of the paper.
2 Moments of deterministic eigenfunctions of point scatterers

The goal of this section is to describe precisely the deterministic setting that we wish to model. In Sect. 2.1, we introduce our framework and recall the definition of a point scatterer on a flat torus. We also study the new eigenfunctions of point scatterers on flat tori and prove these functions are $L^p$ for any $p \in \mathbb{N}^*$. Then, we derive an expression for the moments of any order of these new eigenfunctions and we prove Prop. 1.5 in Sect. 2.2.

2.1 Point scatterers on flat tori

In this section, we introduce our framework and recall the definition of a point scatterer in this setting. Let $\alpha > 0$, we denote by $\mathcal{L}_\alpha = \alpha \mathbb{Z} \oplus \alpha^{-1} \mathbb{Z} \subset \mathbb{R}^2$ and by $\mathcal{L}_\alpha^* = \alpha^{-1} \mathbb{Z} \oplus \alpha \mathbb{Z}$ the dual lattice. We denote by $T_\alpha = \mathbb{R}^2/\mathcal{L}_\alpha$, equipped with the metric induced by the Euclidean inner product on $\mathbb{R}^2$. That is, $T_\alpha$ is the 2-dimensional rectangular flat torus with aspect ratio $\alpha^2$ and total area equal to 1. Here and in the rest of this paper, area is computed with respect to the Lebesgue measure on $T_\alpha$, induced by the one on $\mathbb{R}^2$. When $\alpha = 1$, we simply denote $T = T_1$ for the flat square torus. In the following, we constantly identify points of $\mathbb{R}^2$ with their projection in $T_\alpha$.

Let $\Delta$ denote the Laplace–Beltrami operator on $T_\alpha$. Recall that $\Delta$ is an unbounded, positive, self-adjoint operator on the space $L^2(T_\alpha)$ of square integrable functions from $T_\alpha$ to $\mathbb{C}$. Note that, since we defined $\Delta$ as a positive operator, we have $\Delta = -\frac{\partial^2}{\partial x_1^2} - \frac{\partial^2}{\partial x_2^2}$ in the local coordinates induced by the usual Euclidean coordinates of $\mathbb{R}^2$.

Let $x_0 \in T_\alpha$, and let us define rigorously what a point scatterer at $x_0$ is. Let $\Delta|_{D_0}$ denote the restriction of $\Delta$ to the space $D_0$ of smooth functions from $T_\alpha$ to $\mathbb{C}$ that vanish in some neighborhood of $x_0$. By von Neumann’s theory of self-adjoint extensions, there exists a one-parameter family $(\Delta_\varphi)_{\varphi \in (-\pi, \pi)}$ of unbounded self-adjoint operators on $L^2(T_\alpha)$ that extend $\Delta|_{D_0}$ (cf. [22]). For $\varphi = \pi$, we recover the usual Laplacian. Any element of the family $(\Delta_\varphi)_{\varphi \in (-\pi, \pi)}$ is called a point scatterer at $x_0$. The situation being translation-invariant, from now on we assume that $x_0 = 0$.

For the present purpose, we do not need to go over the details of the definition of the operators $(\Delta_\varphi)_{\varphi \in (-\pi, \pi)}$. In particular, the choice of the parameter $\varphi \in (-\pi, \pi)$ will be irrelevant to us. We refer the interested reader to [15, Sect. 3] for details on this matter.

Let us review the spectral properties of the point scatterers $(\Delta_\varphi)_{\varphi \in (-\pi, \pi)}$. First, recall that the spectrum of the usual Laplacian is $\text{Sp}(\Delta) = \left\{ \frac{4\pi^2}{\alpha^2} (a^2 + \alpha^4 b^2) \mid (a, b) \in \mathbb{N}^2 \right\}$. Its distinct eigenvalues can be ordered into an increasing sequence $(\lambda_k)_{k \geq 0}$ going to infinity. Let $k \geq 0$, denote by:

$$\Lambda_k = \{ \xi \in \mathcal{L}_\alpha^* \mid 4\pi^2 \|\xi\|^2 = \lambda_k \} = \mathcal{L}_\alpha^* \cap \left( \frac{\sqrt{\lambda_k}}{2\pi} \mathbb{S}^1 \right)$$

the set of wave vectors associated with $\lambda_k$, where $\mathbb{S}^1$ denotes the unit circle in $\mathbb{R}^2$. Note that $\Lambda_0 = \{0\}$ and $\mathcal{L}_\alpha^* = \bigsqcup_{k \geq 0} \Lambda_k$. The eigenspace $\ker(\Delta - \lambda_k \text{Id})$ is spanned by the functions $\{ e^{2i\pi \langle \xi, \cdot \rangle} \mid \xi \in \Lambda_k \}$, where $\langle \cdot, \cdot \rangle$ stands for the canonical Euclidean inner product on $\mathbb{R}^2$, and the multiplicity of $\lambda_k$ is $r_k = \dim \ker(\Delta - \lambda_k \text{Id}) = \text{card} \Lambda_k$.

**Remark 2.1.** We have $r_0 = 1$. Besides, $\Lambda_k$ is invariant under the reflections $(x_1, x_2) \mapsto (-x_1, x_2)$ and $(x_1, x_2) \mapsto (x_1, -x_2)$. Hence $r_k$ is even if $k > 0$, and $r_k \in 4\mathbb{N}$ unless $\Lambda_k \cap (\mathbb{R} \times \{0\} \cup \{0\} \times \mathbb{R}) \neq \emptyset$. When $\alpha = 1$, the set $\Lambda_k$ is moreover invariant by $(x_1, x_2) \mapsto (x_2, x_1)$, so that $r_k \in 4\mathbb{N}$ for any $k > 0$ and $r_k \in 8\mathbb{N}$ generically.

Let $\varphi \in (-\pi, \pi)$, in the remainder of this section, we describe the eigenvalues and eigenfunctions of $\Delta_\varphi$. See [15, Sect. 3 and App. A] for more details. For any $k \geq 1$, $\lambda_k$ is an eigenvalue of $\Delta_\varphi$ with multiplicity $r_k - 1$, and the associated eigenspace is:

$$\ker (\Delta_\varphi - \lambda_k \text{Id}) = \{ \phi \in \ker(\Delta - \lambda_k \text{Id}) \mid \phi(0) = 0 \}.$$ 

In addition to the old eigenvalues inherited from $\Delta$, there exists an increasing sequence $(\tau_k^\varphi)_{k \geq 0}$ of new simple real eigenvalues of $\Delta_\varphi$. That is $\text{Sp}(\Delta_\varphi) = \{ \lambda_k \mid k \geq 1 \} \cup \{ \tau_k^\varphi \mid k \geq 0 \}$. Moreover, the sequences $(\lambda_k)_{k \geq 0}$ and $(\tau_k^\varphi)_{k \geq 0}$ are interlaced, in the sense that:

$$\tau_0^\varphi < \lambda_0 < \tau_1^\varphi < \lambda_1 < \tau_2^\varphi < \cdots < \lambda_{k-1} < \tau_k^\varphi < \lambda_k < \cdots.$$
The new eigenvalues of $\Delta_\varphi$ are characterized by the following spectral equation. Let $\tau \in \mathbb{R} \setminus \text{Sp}(\Delta)$, then $\tau \in \text{Sp}(\Delta_\varphi)$ if and only if:

$$
\sum_{k \geq 0} r_k \left( \frac{1}{\lambda_k - \tau} - \frac{\lambda_k}{\lambda_k^2 + 1} \right) = \tan \left( \frac{\varphi}{2} \right) \sum_{k \geq 0} \frac{r_k}{\lambda_k^2 + 1}.
$$

(2.2)

If $\tau \in \mathbb{R} \setminus \text{Sp}(\Delta)$ is a solution of Eq. (2.2), then $\ker (\Delta_\varphi - \tau \text{Id})$ is spanned by the function $G_\tau$ defined below (Def. 2.2). We prove that $G_\tau \in L^2(\mathbb{T}_\alpha)$ in Lem. 2.4.

**Definitions 2.2.** For any $k \in \mathbb{N}$, we denote by $\phi_k$ the function:

$$
\phi_k : \mathbb{T}_\alpha \longrightarrow \mathbb{R}
$$

where $\Lambda_k$ is defined by Eq. (2.1). Moreover, for any $\tau \in \mathbb{R} \setminus \text{Sp}(\Delta)$, we define two function $G_\tau : \mathbb{T}_\alpha \rightarrow \mathbb{R}$ and $f_\tau : \mathbb{T}_\alpha \rightarrow \mathbb{R}$ by:

$$
G_\tau = \sum_{k \geq 0} \frac{\phi_k}{\lambda_k - \tau} \quad \text{and} \quad f_\tau = G_\tau + \frac{1}{\tau} = \sum_{k \geq 1} \frac{\phi_k}{\lambda_k - \tau}.
$$

Remark 2.3. The sets $\Lambda_k$ are invariant by $(x_1, x_2) \mapsto (-x_1, -x_2)$. Hence, $\phi_k$ is indeed real-valued for any $k \in \mathbb{N}$, and $G_\tau$ and $f_\tau$ are real-valued for any $\tau \in \mathbb{R} \setminus \text{Sp}(\Delta)$.

In the following, we study the asymptotics as $\tau \to +\infty$ of the moments of $f_\tau$ (resp. $G_\tau$). We will consider any $\tau \in \mathbb{R} \setminus \text{Sp}(\Delta)$, not only the solutions of Eq. (2.2). This way, the problem no longer depends on the parameter $\varphi \in (-\pi, \pi)$, that is on the choice of a self-adjoint extension of $\Delta_{D_\varphi}$. First, we must check that $f_\tau$ (resp. $G_\tau$) is a well-defined element of $L^p(\mathbb{T}_\alpha)$, for any positive integer $p$. This is the purpose of Lem. 2.4 below.

**Lemma 2.4.** Let $p \in \mathbb{N}^*$, for any $\tau \in \mathbb{R} \setminus \text{Sp}(\Delta)$, we have $f_\tau \in L^p(\mathbb{T}_\alpha)$ (resp. $G_\tau \in L^p(\mathbb{T}_\alpha)$). More precisely, the truncated series

$$
\sum_{k=1}^n \frac{\phi_k}{\lambda_k - \tau}
$$

converge in $L^p(\mathbb{T}_\alpha)$ as $n \to +\infty$.

**Remarks 2.5.**

- The proof is adapted from [12], where this result is proved for $p = 4$.

  - For $p = 2$, it is possible to give a simpler proof, using the Hilbert space structure of $L^2(\mathbb{T}_\alpha)$.

  - The series defining $f_\tau$ does not converge absolutely in $L^p(\mathbb{T}_\alpha)$ in general, even for $p = 2$.

**Proof.** Let us fix $p \in \mathbb{N}^*$ and $\tau \in \mathbb{R} \setminus \text{Sp}(\Delta)$. Let $\lambda > 0$ and let $\lambda' \in [\lambda, 2\lambda]$, we denote by $A(\lambda, \lambda') = \{ \xi \in L^p_\alpha \mid \lambda < 4\pi^2 \| \xi \|^2 \leq \lambda' \}$. This set is finite, and we denote by:

$$
\mathcal{h}_{\lambda, \lambda'} = \sum_{\{k \geq 1 \mid \lambda < \lambda_k \leq \lambda'\}} \frac{\phi_k}{\lambda_k - \tau} = \sum_{\xi \in A(\lambda, \lambda')} \frac{e^{2\pi i \langle \xi, . \rangle}}{4\pi^2 \| \xi \|^2 - \tau}.
$$

(2.3)

Since $\mathbb{T}_\alpha$ has unit area, by Jensen’s inequality we have $\| \mathcal{h}_{\lambda, \lambda'} \|_p \leq \| \mathcal{h}_{\lambda, \lambda'} \|_{2p}$, where $\| \cdot \|_p$ stands for the $L^p$ norm associated with the Lebesgue measure on $\mathbb{T}_\alpha$. Then, $\| \mathcal{h}_{\lambda, \lambda'} \|_{2p}$ equals

$$
\int_{\mathbb{T}_\alpha} \int_{\mathbb{T}_\alpha} \mathcal{h}_{\lambda, \lambda'}(x)^{2p} dx = \sum_{\xi_1, \ldots, \xi_{2p} \in A(\lambda, \lambda')} \left( \prod_{j=1}^{2p} (4\pi^2 \| \xi_j \|^2 - \tau) \right)^{-1} \int_{\mathbb{T}_\alpha} \exp \left( 2\pi \sum_{j=1}^{2p} \langle \xi_j, x \rangle \right) dx.
$$

For any $\xi_1, \ldots, \xi_{2p} \in A(\lambda, \lambda')$, we have:

$$
\int_{\mathbb{T}_\alpha} \exp \left( 2\pi \sum_{j=1}^{2p} \langle \xi_j, x \rangle \right) dx = \begin{cases}
1, & \text{if } \sum_{j=1}^{2p} \xi_j = 0, \\
0, & \text{otherwise}.
\end{cases}
$$

12
Moreover, as \( \lambda \to +\infty \), we have \( \prod_{j=1}^{2p} (4\pi^2 \|\xi_j\|^2 - \tau) \sim \prod_{j=1}^{2p} 4\pi^2 \|\xi_j\|^2 \geq \lambda^{2p} \). So that, for any \( \lambda \) large enough, \( \prod_{j=1}^{2p} (4\pi^2 \|\xi_j\|^2 - \tau) \geq \frac{1}{2} \lambda^{2p} \). Besides,

\[
\text{card} \left\{ (\xi_1, \ldots, \xi_{2p}) \in A(\lambda, \lambda')^{2p} \left| \sum_{j=1}^{2p} \xi_j = 0 \right. \right\} \leq \text{card}(A(\lambda, \lambda'))^{2p-1}.
\]

By Weyl’s Law (Thm. 1.15), for any \( \lambda \) large enough and \( \lambda' \in [\lambda, 2\lambda] \), we have \( \text{card}(A(\lambda, \lambda')) \leq \frac{1}{2} \). Hence \( \|h_{\lambda, \lambda'}\|_{2p} \leq \lambda^{-1} \) and \( \|h_{\lambda, \lambda'}\|_p \leq \lambda^{-\frac{p}{2}} \). In particular, this shows that, for any \( p \in \mathbb{N}^* \), for any \( \tau \in \mathbb{R} \setminus \text{Sp}(\Delta) \), we have:

\[
\|h_{\lambda, \lambda'}\|_p = O \left( \lambda^{-\frac{p}{2}} \right)
\]

as \( \lambda \to +\infty \), where the constant involved in the \( O \) notation does not depend on \( \lambda' \in [\lambda, 2\lambda] \).

Let \( n \geq 0 \) and let us denote by \( L = \lfloor \log_2(\lambda_n) \rfloor \). We have:

\[
\left\| \sum_{k \geq n} \frac{\phi_k}{\lambda_k - \lambda} \right\|_p = \left\| \sum_{\ell \geq L} \sum_{k \geq 1} \frac{\phi_k}{\lambda_k - \tau} - \sum_{\ell \geq L} \sum_{k \geq 1} \frac{\phi_k}{\lambda_k - \tau} \right\|_p \\
\leq \|h_{2^\ell, \lambda_n}\|_p + \sum_{\ell \geq L} \|h_{2^\ell, 2^{\ell+1}}\|_p \\
= O \left( (2^L)^{-\frac{p}{2}} \right) = O \left( (\lambda_n)^{-\frac{p}{2}} \right) \underset{n \to +\infty}{\longrightarrow} 0.
\]

Thus, the sequence \( \left( \sum_{k \geq n} \frac{\phi_k}{\lambda_k - \tau} \right)_{n \geq 0} \) converges in \( L^p(\mathbb{T}_\alpha) \), hence is a Cauchy sequence. Therefore \( \left( \sum_{k \geq 1} \frac{\phi_k}{\lambda_k - \tau} \right)_{n \geq 0} \) is also a Cauchy sequence, and converges in \( L^p(\mathbb{T}_\alpha) \).  

### 2.2 Moments of the new eigenfunctions

In this section, we study the central moments of the new eigenfunctions of a point scatterer at 0 in \( \mathbb{T}_\alpha \), where \( \alpha > 0 \). More generally, we study the moments of the functions \( f_\tau \), for \( \tau \in \mathbb{R} \setminus \text{Sp}(\Delta) \) (see Def. 2.2). The main point is the proof of Prop. 1.5, in which we derive an expression of these moments. The content of this section roughly corresponds to Step 1 in Sect. 1.2.

**Lemma 2.6.** For any \( \tau \in \mathbb{R} \setminus \text{Sp}(\Delta) \), we have:

\[
\int_{\mathbb{T}_\alpha} f_\tau(x) \, dx = 0, \quad \int_{\mathbb{T}_\alpha} (f_\tau(x))^2 \, dx = \sum_{k \geq 1} \frac{r_k}{(\lambda_k - \tau)^2},
\]

\[
\int_{\mathbb{T}_\alpha} G_\tau(x) \, dx = -\frac{1}{\tau}, \quad \int_{\mathbb{T}_\alpha} (G_\tau(x))^2 \, dx = \sum_{k \geq 0} \frac{r_k}{(\lambda_k - \tau)^2},
\]

where, as before, \( (\lambda_k)_{k \geq 0} \) is the increasing sequence of distinct eigenvalues of \( \Delta \) and, for any \( k \geq 0 \), \( r_k \) is the multiplicity of \( \lambda_k \).

**Proof.** We give the proof in the case of \( f_\tau \), the proof is similar for \( G_\tau \). Recall that the family \( \{ e^{2i\pi \xi \cdot \cdot} \mid \xi \in \mathcal{L}_\alpha \} \) is a Hilbert basis of \( L^2(\mathbb{T}_\alpha) \). Recall also that:

\[
f_\tau = \sum_{k \geq 1} \sum_{\xi \in \Lambda_k} \frac{e^{2i\pi \xi \cdot \cdot}}{\lambda_k - \tau}.
\]

Denoting by \( \langle \cdot, \cdot \rangle \) the \( L^2 \) inner product on \( L^2(\mathbb{T}_\alpha) \) and by \( 1 \) the constant unit function, we have:

\[
\int_{\mathbb{T}_\alpha} f_\tau(x) \, dx = \langle f_\tau, 1 \rangle = 0.
\]

Besides, by Parseval’s Identity,

\[
\int_{\mathbb{T}_\alpha} (f_\tau(x))^2 \, dx = \|f_\tau\|^2 = \sum_{k \geq 1} \frac{\text{card}(\Lambda_k)}{(\lambda_k - \tau)^2} = \sum_{k \geq 1} \frac{r_k}{(\lambda_k - \tau)^2}. \quad \Box
\]
As we already explained in Sect. 1.2, we are interested in the central moments of the random variable $G_{\tau}(X)$, where $X$ is a uniform random variable in $(T_\alpha, dx)$. With this probabilistic point of view, Lem. 2.4 states that, for any $p \in \mathbb{N}^*$ and $\tau \in \mathbb{R} \setminus \text{Sp}(\Delta)$, both $G_{\tau}(X)$ and $f_{\tau}(X)$ are $L^p$ random variables. Moreover, by Lem. 2.6, the expectation of $G_{\tau}(X)$ equals $-\frac{1}{\lambda}$. Hence, $f_{\tau}(X) = G_{\tau}(X) + \frac{1}{\lambda}$ is the centered random variable associated with $G_{\tau}(X)$. In particular, the central moments of $G_{\tau}(X)$ are simply the corresponding moments of $f_{\tau}(X)$. In the following, we focus on studying the moments of $f_{\tau}(X)$.

**Definition 2.7.** For any $p \in \mathbb{N}^*$ and any $\tau \in \mathbb{R} \setminus \text{Sp}(\Delta)$, we denote by $M^p_\tau = \int_{T_\alpha} f_{\tau}(x)^p \, dx$, the $p$-th moment of $f_{\tau}$.

Note that $f_{\tau}$ is not $L^2$-normalized. Indeed, $M^2_\tau = \|f_{\tau}\|_2^2$ is given by Lem. 2.6, and is not equal to 1 in general. We are ultimately interested in studying the asymptotics, as $\tau \to +\infty$, of the normalized moments $(M^2_\tau)^{-\frac{\tau}{2}} M^p_\tau$, for $p \in \mathbb{N}^*$, that is the moments of the normalized function $\|f_{\tau}\|_2^{-1} f_{\tau}$. It is more convenient to work with the sequence $(M^p_\tau)_{p \geq 1}$ for now and only consider the normalized moments later on.

We conclude this section with the proof of Prop. 1.5.

**Proof of Prop. 1.5.** Let $p \in \mathbb{N}^*$ and let $\tau \in \mathbb{R} \setminus \text{Sp}(\Delta)$. For any $l \in \mathbb{Z}$, let us denote by $A_l$ the finite set $A(2^l, 2^{l+1}) = \{ \xi \in \mathcal{L}_\alpha^* \mid 2^l \leq 4\pi^2 \|\xi\|^2 \leq 2^{l+1} \}$ and by

$$h_l = h_{2^l, 2^{l+1}} = \sum_{\{k \geq 1\mid 2^k \leq \lambda_k \leq 2^{k+1}\}} \frac{\phi_k}{\lambda_k - \tau} = \sum_{\xi \in A_l} \frac{\lambda^{2\pi \xi(\xi, \cdot)}}{4\pi^2 \|\xi\|^2 - \tau}.$$  

Note that these functions already appeared in the proof of Lem. 2.4 (see Eq. (2.3)).

Let us denote by $L = \lfloor \log_2(\lambda_1) \rfloor + 1$. Recalling Def. 2.2, we have $f_{\tau} = \sum_{l \geq L} h_l$, where the sum converges absolutely in $L^p(T_\alpha)$ by Eq. (2.4). Then, we have:

$$M^p_\tau = \int_{T_\alpha} \left( \sum_{l \geq L} h_l(x) \right)^p \, dx = \int_{T_\alpha} \sum_{l_1, \ldots, l_p \geq L} \left( \prod_{j=1}^p h_{l_j}(x) \right) \, dx = \sum_{l_1, \ldots, l_p \geq L} \prod_{j=1}^p h_{l_j}(x) \, dx.$$  

We obtain the last equality by exchanging the integral and the sum. This is possible because:

$$\sum_{l_1, \ldots, l_p \geq L} \int_{T_\alpha} \prod_{j=1}^p h_{l_j}(x) \, dx = \sum_{l_1, \ldots, l_p \geq L} \left\| \prod_{j=1}^p h_{l_j} \right\|_1 \leq \sum_{l_1, \ldots, l_p \geq L} \prod_{j=1}^p \left\| h_{l_j} \right\|_p = \left( \sum_{l \geq L} \left\| h_l \right\|_p \right)^p < +\infty,$$

where the middle inequality is Hölder’s, and the finiteness of the last term is a consequence of Eq. (2.4), as we already explained. For any $l_1, \ldots, l_p \geq L$, we have:

$$\prod_{j=1}^p h_{l_j} = \prod_{j=1}^p \sum_{\xi \in A_{l_j}} \frac{\lambda^{2\pi \xi(\xi, \cdot)}}{4\pi^2 \|\xi\|^2 - \tau} = \sum_{(\xi_1, \ldots, \xi_p) \in A_{l_1} \times \cdots \times A_{l_p}} \left( \prod_{j=1}^p \frac{\lambda^{2\pi \xi(\xi_j, \cdot)}}{4\pi^2 \|\xi_j\|^2 - \tau} \right).$$

Since these sums are indexed by finite sets, we have:

$$M^p_\tau = \sum_{l_1, \ldots, l_p \geq L} \int_{T_\alpha} \prod_{j=1}^p h_{l_j}(x) \, dx = \sum_{l_1, \ldots, l_p \geq L} \sum_{(\xi_1, \ldots, \xi_p) \in A_{l_1} \times \cdots \times A_{l_p}} \int_{T_\alpha} \prod_{j=1}^p \frac{\lambda^{2\pi \xi(\xi_j, x)}}{4\pi^2 \|\xi_j\|^2 - \tau} \, dx.$$  

Then,

$$\bigcup_{l \geq L} A_l = \left\{ \xi \in \mathcal{L}_\alpha^* \mid 2^L \leq 4\pi^2 \|\xi\|^2 \right\} = \mathcal{L}_\alpha^* \setminus \{0\} = \bigcup_{k \geq 1} \Lambda_k,$$
where the second equality comes from the fact that \( \lambda_1 = \min \left\{ 4\pi^2 \|\xi\|^2 \mid \xi \in \mathcal{L}_\alpha^* \setminus \{0\} \right\} \). Hence,

\[
M_p^r = \sum_{\xi_1, \ldots, \xi_p \in \mathcal{L}_\alpha^* \setminus \{0\}} \int_{\mathbb{T}_\alpha} \prod_{j=1}^p \frac{e^{2i\pi (\xi_j, x)}}{4\pi^2 \|\xi_j\|^2 - \tau} \, dx
= \sum_{k_1, \ldots, k_p \geq 1} \sum_{(\xi_1, \ldots, \xi_p) \in \Lambda_{k_1} \times \cdots \times \Lambda_{k_p}} \int_{\mathbb{T}_\alpha} \prod_{j=1}^p \frac{e^{2i\pi (\xi_j, x)}}{4\pi^2 \|\xi_j\|^2 - \tau} \, dx
= \sum_{k_1, \ldots, k_p \geq 1} \left( \prod_{j=1}^p \frac{1}{\lambda_{k_j} - \tau} \right)^{a_k} \sum_{(\xi_1, \ldots, \xi_p) \in \Lambda_{k_1} \times \cdots \times \Lambda_{k_p}} \exp \left( 2i\pi \left\langle \sum_{j=1}^p \xi_j, x \right\rangle \right) \, dx
= \sum_{k_1, \ldots, k_p \geq 1} \left( \prod_{j=1}^p \frac{1}{\lambda_{k_j} - \tau} \right)^{a_k} \text{card} \left\{ (\xi_1, \ldots, \xi_p) \in \prod_{j=1}^p \Lambda_{k_j} \left| \sum_{j=1}^p \xi_j = 0 \right. \right\}.
\]

Let \( k_1, \ldots, k_p \geq 1 \), for any \( k \geq 1 \), we denote by \( a_k = \text{card} \{ j \in \{1, \ldots, p\} \mid k_j = k \} \). Then \( a = (a_k)_{k \geq 1} \in \ell_0 \) and \( |a| = p \). Moreover,

\[
\prod_{j=1}^p \frac{1}{\lambda_{k_j} - \tau} = \prod_{k \geq 1} \left( \frac{1}{\lambda_k - \tau} \right)^{a_k},
\]

and, recalling Def. 1.4 and reordering the terms of the Cartesian product, we have:

\[
\text{card} \left\{ (\xi_1, \ldots, \xi_p) \in \prod_{j=1}^p \Lambda_{k_j} \left| \sum_{j=1}^p \xi_j = 0 \right. \right\} = N_a.
\]

Conversely, let \( a = (a_k)_{k \geq 1} \in \ell_0 \) be such that \( |a| = p \). The choice of \( k_1, \ldots, k_p \geq 1 \) such that, for any \( k \geq 1 \), \( a_k = \text{card} \{ j \in \{1, \ldots, p\} \mid k_j = k \} \) corresponds to the choice of a partition of \( \{1, \ldots, p\} \) into subsets of cardinalities \( a_0, a_1, \ldots, a_k, \ldots \). The number of such partitions is \( p! (a!)^{-1} \). Thus,

\[
M_p^r = p! \sum_{a \in \ell_0, |a| = p} \frac{N_a}{a!} \prod_{k \geq 1} \left( \frac{1}{\lambda_k - \tau} \right)^{a_k}.
\]

\section{Random model for the moments of the new eigenfunctions}

In this section, we study the random model introduced in Sect. 1.2 for the central moments of the new eigenfunctions of a point scatterer on a rectangular flat torus \( \mathbb{T}_\alpha \), where \( \alpha > 0 \). We start from the expression of these moments derived in Prop. 1.5, and we randomize first the wave vectors sets \( (\Lambda_k)_{k \geq 1} \), then the spectrum \( (\lambda_k)_{k \geq 1} \) of \( \Delta \). The content of Sect. 3.1 corresponds to what we called Step 2 in the Introduction (Sect. 1.2), that is the randomization of the wave vectors. The main goal of Sect. 3.1 is the proof of Prop. 1.13. In Sect. 3.2, we randomize the spectrum of the Laplacian (Step 3 in Sect. 1.2). In Sect. 3.3, we study the limit distribution of the spectral sums introduced in Def. 1.12. Finally, we prove our main result (Thm. 1.22) in Sect. 3.4.

\subsection{Randomization of the wave vectors}

This section corresponds to the second step in the construction of our random model, that is the randomization of the sets of wave vectors \( (\Lambda_k)_{k \geq 1} \) sets (cf. Step 2 in Sect. 1.2). In Sect. 3.1.1, we work in the setting described in the Introduction (Sect. 1.2) and we prove Prop. 1.13. In Sect. 3.1.2, we consider the special case of the square torus (\( \alpha = 1 \)). In this setting, we define a variation on our random model with some additional symmetries and show that the results of Sect. 3.1.1 remain valid for this alternative model.
3.1.1 Almost sure expression of the moments

The goal of this section is the proof of Prop. 1.13 in the setting described in Step 2 in Sect. 1.2. We assume that we are given an increasing sequence \((\lambda_k)_{k \geq 1}\) of positive numbers. This sequence can be thought of as the spectrum of the Laplacian on some \(T_\alpha\), or its randomized version. We also fix a sequence \((m_k)_{k \geq 1}\) of positive integers. For each \(k \geq 1\), \(m_k\) is meant to model the number of wave vectors associated with \(\lambda_k\) that have non-negative coordinates. Let \((\theta_{k,j})_{j \geq 1}\) denote a sequence of random variables in \([0, \frac{\pi}{2}]\) whose distribution admits a density with respect to the measure \(\eta\) (see Def. 1.6). As in Sect. 1.2, we define the randomized wave vectors sets \((\Lambda_k)_{k \geq 1}\) by Def. 1.7. For all \(k \geq 1\), we denote by \(r_k = \text{card}(\Lambda_k)\), as in the deterministic case.

**Remark 3.1.** Almost surely, for all \(k\) and \(j \geq 1\), we have \(\theta_{k,j} \in (0, \frac{\pi}{2})\). This is true for \(\eta\), hence for any distribution which is absolutely continuous with respect to \(\eta\). In particular, almost surely, for all \(k \geq 1\), we have \(r_k = 4m_k\).

Now that we defined a sequence \((\Lambda_k)_{k \geq 1}\) of random finite subsets of \(\mathbb{R}^2\), we can define a random sequence of integers \((N_a)_{a \in \ell_0}\) by Def. 1.4. Recalling the deterministic expression of the moments obtained in Prop. 1.5, we define the randomized moments as follows.

**Definition 3.2.** In the setting we just described, for any \(p \in \mathbb{N}^+\) and \(\tau \in \mathbb{R} \setminus \{\lambda_k \mid k \geq 1\}\), we define the randomized moment \(M^p_\tau\) by:

\[
M^p_\tau = p! \sum_{a \in \ell_0 : |a| = p} \frac{N_a}{a!} \prod_{k \geq 1} \left(\frac{1}{\lambda_k - \tau}\right)^{a_k}.
\]

Note that it is not clear that the series defining \(M^p_\tau\) makes sense almost surely. We prove that it is the case in Cor. 3.4 below. This result will be a corollary of the following almost sure expression of the sequence \((N_a)_{a \in \ell_0}\).

**Lemma 3.3.** In the setting of this section, almost surely, for all \(a = (a_k)_{k \geq 1} \in \ell_0\) we have:

\[
N_a = a! \prod_{k \geq 1} \left(\sum_{b \in \mathbb{N}^m_{m_k}} \frac{b_j}{\prod_{j=0}^{b_j} (c_j!)} \cdot \left(\frac{1}{c_j} \right)^2\right).
\]

In particular, almost surely, \(N_a\) only depends on \((a_k)_{k \geq 1}\) and \((m_k)_{k \geq 1}\). Moreover, if there exists \(k \geq 1\) such that \(a_k\) is odd, then \(N_a = 0\).

**Proof.** Let \(a = (a_k)_{k \geq 1} \in \ell_0\). Let \((\xi_{k,l})_{k \geq 1, l \leq a_k}\) be such that, for all \(k \geq 1\) and \(l \in \{1, \ldots, a_k\}\), \(\xi_{k,l} \in \Lambda_k\). Then, for any \((k,l)\), there exists a unique \((i_{k,l}, j_{k,l}) \in \{1, 2, 3, 4\} \times \{1, \ldots, m_k\}\) such that:

\[
\xi_{k,l} = \sum_{i=1}^{m_k} \frac{\sqrt{\lambda_k}}{2\pi} \zeta^{(i,1)}(\theta_{k,j_{k,l}}).
\]

Here we used the notation \(\zeta^{(i,1)}(\theta)\) introduced in Def. 1.7. Thus, we have:

\[
N_a = \text{card} \left\{(i_{k,l}, j_{k,l}) \in \prod_{k \geq 1} (\{1, 2, 3, 4\} \times \{1, \ldots, m_k\})^{a_k} \mid \sum_{k \geq 1} \sum_{i=1}^{a_k} \frac{\sqrt{\lambda_k}}{2\pi} \zeta^{(i,1)}(\theta_{k,j_{k,l}}) = 0 \right\}.
\]

Let us consider some sequence \((i_{k,l}, j_{k,l}) \in \prod_{k \geq 1} (\{1, 2, 3, 4\} \times \{1, \ldots, m_k\})^{a_k}\). For any \(k \geq 1\), any \(j \in \{1, \ldots, m_k\}\) and any \(i \in \{1, 2, 3, 4\}\), we denote by:

\[
c_i(k, j) = \text{card} \left\{l \in \{1, \ldots, a_k\} \mid (i_{k,l}, j_{k,l}) = (i, j) \right\}.
\]

(3.1)

Note that \(\sum_{k \geq 1} \sum_{i=1}^{a_k} c_i(k, j) = \sum_{k \geq 1} a_k = |a| < +\infty\). In particular, \(c_i(k, j) = 0\) for all \((k, j, i)\) but a finite number. With these notations, we have:

\[
\sum_{k \geq 1} \sum_{i=1}^{a_k} \frac{\sqrt{\lambda_k}}{2\pi} \zeta^{(i,1)}(\theta_{k,j_{k,l}}) = \sum_{k \geq 1} \sum_{j=1}^{m_k} \frac{\sqrt{\lambda_k}}{2\pi} c_i(k, j) \zeta^{(i)}(\theta_{k,j})
\]

\[
= \sum_{k \geq 1} \sum_{j=1}^{m_k} \frac{\sqrt{\lambda_k}}{2\pi} \left( c_1(k, j) - c_2(k, j) - c_3(k, j) + c_4(k, j) \cos(\theta_{k,j}) \right).
\]
If \((i_{k,l}, j_{k,l})_{k \geq 1; 1 \leq l \leq a_k}\) is such that for any \(k \geq 1\) and any \(j \in \{1, \ldots, m_k\}\) we have:
\[
\begin{align*}
&c_1(k,j) - c_2(k,j) - c_3(k,j) + c_4(k,j) = 0, \\
&c_1(k,j) + c_2(k,j) - c_3(k,j) - c_4(k,j) = 0,
\end{align*}
\]
then
\[
\sum_{k \geq 1} \sum_{l=1}^{a_k} \frac{\sqrt{\lambda_k}}{2\pi} \zeta^{(i_{k,l})}(\theta_{k,j_{k,l}}) = 0
\]
and the sequence \((i_{k,l}, j_{k,l})_{k \geq 1; 1 \leq l \leq a_k}\) contributes to \(N_a\).

On the other hand, let us consider \((i_{k,l}, j_{k,l})_{k \geq 1; 1 \leq l \leq a_k}\) such that one of the relations (3.2) is not satisfied. Let us prove that, in this case, \(\sum_{k \geq 1} \sum_{l=1}^{a_k} \frac{\sqrt{\lambda_k}}{2\pi} \zeta^{(i_{k,l})}(\theta_{k,j_{k,l}}) \neq 0\) for almost every \((\theta_{k,j})_{k,l \geq 1}\), i.e. the sequence \((i_{k,l}, j_{k,l})_{k \geq 1; 1 \leq l \leq a_k}\) almost surely does not contribute to \(N_a\).

Without loss of generality, we can assume that there exists \(k \geq 1\) and \(j \in \{1, \ldots, m_k\}\) such that:
\[
c_1(k_1,j_1) - c_2(k_1,j_1) - c_3(k_1,j_1) + c_4(k_1,j_1) \neq 0.
\]

There are at most \(|a|\) couples \((k,j)\) such that \(c_1(k,j) \neq 0\) for some \(i \in \{1, 2, 3, 4\}\). One of these couples is \((k_1,j_1)\). Let us denote by \((k_2,j_2), \ldots, (k_q,j_q)\) the others. Let \((\theta_{k,j})_{k,j \geq 1} \in [0, \frac{\pi}{2}]^{\mathbb{R} \times \mathbb{N}}\), for any \(l \in \{1, \ldots, q\}\), we denote \(\theta_l = \theta_{k_l,j_l}\), for simplicity. If
\[
\sum_{k \geq 1} \sum_{l=1}^{a_k} \frac{\sqrt{\lambda_k}}{2\pi} \zeta^{(i_{k,l})}(\theta_{k,j_{k,l}}) = 0,
\]
then we have:
\[
0 = \sum_{k \geq 1} \sum_{j=1}^{m_k} \frac{\sqrt{\lambda_k}}{2\pi} \left( c_1(k,j) - c_2(k,j) - c_3(k,j) + c_4(k,j) \right) \cos(\theta_{k,j}) \\
= \sum_{j=1}^{q} \frac{\sqrt{\lambda_{k_j}}}{2\pi} \left( c_1(k_1,j_1) - c_2(k_1,j_1) - c_3(k_1,j_1) + c_4(k_1,j_1) \right) \cos(\theta_{k_1,j_1}) \\
= F(\theta_1, \theta_2, \ldots, \theta_q),
\]
where the last line defines \(F : [0, \frac{\pi}{2}]^q \to \mathbb{R}\). For any \((\theta_1, \ldots, \theta_q) \in (0, \frac{\pi}{2})^q\), we have:
\[
\frac{\partial F}{\partial \theta_1}(\theta_1, \ldots, \theta_q) = -\frac{\sqrt{\lambda_{k_1}}}{2\pi} \left( c_1(k_1,j_1) - c_2(k_1,j_1) - c_3(k_1,j_1) + c_4(k_1,j_1) \right) \sin(\theta_1) \neq 0.
\]
Thus \(F\) is a smooth submersion on \((0, \frac{\pi}{2})^q\), and \(F^{-1}(0) \cap (0, \frac{\pi}{2})^q\) is a smooth hypersurface in \((0, \frac{\pi}{2})^q\).

Hence, \(F^{-1}(0)\) is included in the union of the boundary of \([0, \frac{\pi}{2}]^q\) and a smooth hypersurface of \((0, \frac{\pi}{2})^q\). Since we assumed that the distribution of \((\theta_{k,j})_{k,j \geq 1}\) is absolutely continuous with respect to \(\eta\), then the distribution of \((\theta_1, \ldots, \theta_q)\) is absolutely continuous with respect to the Lebesgue measure on \([0, \frac{\pi}{2}]^q\). Hence, the measure of \(F^{-1}(0)\) equals 0, that is \(F(\theta_1, \ldots, \theta_q) \neq 0\) almost surely. This proves that, if one of the conditions (3.2) is not satisfied, then almost surely
\[
\sum_{k \geq 1} \sum_{l=1}^{a_k} \frac{\sqrt{\lambda_k}}{2\pi} \zeta^{(i_{k,l})}(\theta_{k,j_{k,l}}) \neq 0
\]
and only if the conditions (3.2) are satisfied.

Since \(\ell_0\) is countable, almost surely, for every \(a \in \ell_0\), we have:
\[
N_a = \text{card} \left\{ (i_{k,l}, j_{k,l})_{k \geq 1; 1 \leq l \leq a_k} \mid \forall(k,j), \begin{cases} c_1(k,j) - c_2(k,j) - c_3(k,j) + c_4(k,j) = 0, \\ c_1(k,j) + c_2(k,j) - c_3(k,j) - c_4(k,j) = 0 \end{cases} \right\},
\]
where the \(c_i(k,j)\) are defined by Eq. (3.1). In the following, we only consider the full-measure set on which the \((N_a)_{a \in \ell_0}\) are defined by the previous formula. Let \(a = (a_k)_{k \geq 1} \in \ell_0\) and let \((i_{k,l}, j_{k,l})_{(k,l)} \in \prod_{k \geq 1} \{(1,2,3,4) \times \{1, \ldots, m_k\}\}^{a_k}\).

For any \(k \geq 1\) and \(j \in \{1, \ldots, m_k\}\), we set
\[
b_{k,j} = \text{card} \left\{ l \in \{1, \ldots, a_k\} \mid j_{k,l} = j \right\}.
\]
Then, for any \((k,j), (i_{k,l}, j_{k,l})_{k \geq 1; 1 \leq l \leq a_k}\) satisfies Eq. (3.2) if and only if the following holds:
\[
\begin{align*}
&\begin{cases} c_1(k,j) - c_2(k,j) - c_3(k,j) + c_4(k,j) = 0, \\ c_1(k,j) + c_2(k,j) - c_3(k,j) - c_4(k,j) = 0 \end{cases}, \\
&c_1(k,j) = c_3(k,j), \\
&c_2(k,j) = c_4(k,j), \\
&c_1(k,j) + c_2(k,j) + c_3(k,j) + c_4(k,j) = b_{k,j}, \\
&2(c_1(k,j) + c_2(k,j)) = b_{k,j}.
\end{align*}
\]
Hence, the sequence \((i_k, j_k)_{k \geq 1, 1 \leq \ell \leq a_k}\) contributes to the count of \(N_a\) if and only, for all \(k \geq 1\) and \(j \in \{1, \ldots, m_k\}\), the integer \(b_{k,j}\) is even and there exists \(c_{k,j} \in \mathbb{N}\) such that \(c_1(k, j) = c_3(k, j) = c_{k,j}\) and \(c_2(k, j) = c_4(k, j) = \frac{1}{2} b_{k,j} - c_{k,j}\). In particular, for all \(k \geq 1\), \(a_k = \sum_{j=1}^{m_k} b_{k,j}\) must be even.

This shows that, if there exists \(k \geq 1\) such that \(a_k\) is odd, then \(N_a = 0\). Conversely, let \(a\) be such that \(a_k\) is even for any \(k \geq 1\). For any \(k \geq 1\), let \((b_{k,j})_{1 \leq j \leq m_k}\) be even integers such that \(a_k = \sum_{j=1}^{m_k} b_{k,j}\). For any \(k \geq 1\) and \(j \in \{1, \ldots, m_k\}\), let \(c_{k,j} \in \{0, \ldots, \frac{1}{2} b_{k,j}\}\). Then, the number of sequences \((i_k, j_k)\) \(\in \bigotimes_{k \geq 1} \{(1, 2, 3, 4) \times \{1, \ldots, m_k\}\}\) such that

\[
c_1(k, j) = c_3(k, j) = c_{k,j} \quad \text{and} \quad c_2(k, j) = c_4(k, j) = \frac{1}{2} b_{k,j} - c_{k,j}
\]
equals

\[
\prod_{k \geq 1} \left( \frac{a_k!}{\prod_{j=1}^{m_k} b_{k,j}!} \prod_{j=1}^{m_k} \frac{b_{k,j}!}{(c_{k,j}! (\frac{1}{2} b_{k,j} - c_{k,j})!)^2} \right) = a! \prod_{k \geq 1} \prod_{j=1}^{m_k} \left( \frac{1}{c_{k,j}! (\frac{1}{2} b_{k,j} - c_{k,j})!} \right)^2.
\]

Thus, if \(a_k\) is even for any \(k \geq 1\), we have:

\[
N_a = a! \prod_{k \geq 1} \left( \sum_{\substack{(b_{k,j}) \in \mathbb{N}^{m_k} \setminus \{2 \sum_{j=1}^{m_k} b_{k,j} = a_k\} \cap \{0 \leq c_{k,j} \leq b_{k,j}\} \setminus \{0\}}} \prod_{j=1}^{m_k} \frac{b_{j,j}!}{(c_{k,j}! (\frac{1}{2} b_{k,j} - c_{k,j})!)^2} \right)
\]

\[
= \prod_{k \geq 1} \left( \sum (b_{k,j}) \in \mathbb{N}^{m_k} \setminus \{2 \sum_{j=1}^{m_k} b_{k,j} = a_k\} \cap \{0 \leq c_{k,j} \leq b_{k,j}\} \setminus \{0\} \right) \prod_{j=1}^{m_k} \frac{b_{j,j}!}{(c_{k,j}! (\frac{1}{2} b_{k,j} - c_{k,j})!)^2} \right).
\]

The last term still makes sense if one of the \((a_k)_{k \geq 1}\) is odd. In this case, one of the sums is indexed by the empty set, hence equals 0. This yields the result. \(\square\)

As a corollary, we can prove that Def. 3.2 almost surely makes sense.

**Corollary 3.4.** Almost surely, for any \(p \in \mathbb{N}^+\) and \(\tau \in \mathbb{R} \setminus \{\lambda_k \mid k \geq 1\}\) we have \(M_{\tau}^{2p-1} = 0\) and

\[
M_{\tau}^{2p} = (2p)! \sum_{a \in \ell_0: |a| = p} \prod_{k \geq 1} \left( \frac{1}{\lambda_k - \tau} \right)^{a_k} \sum_{(b_{j}) \in \mathbb{N}^{m_k}} \prod_{j=1}^{m_k} \frac{1}{(\frac{1}{2} (b_{j} - c)!)^2}
\]

where the sum make sense in \([0, +\infty)\) as a sum of non-negative terms.

**Proof.** The sequence \((N_a)_{a \in \ell_0}\) is almost surely given by Lem. 3.3. From now on, we only consider the corresponding full-measure event.

Let \(p \in \mathbb{N}^+\) and \(\tau \in \mathbb{R} \setminus \{\lambda_k \mid k \geq 1\}\). If \(a \in \ell_0\) is such that \(|a| = 2p - 1\), then at least one of the terms \((a_k)_{k \geq 1}\) is odd and \(N_a = 0\). Thus, all the terms in the sum defining \(M_{\tau}^{2p-1}\) vanish (see Def. 3.2) and \(M_{\tau}^{2p-1} = 0\). By the same argument, we can rewrite \(M_{\tau}^{2p}\) as:

\[
M_{\tau}^{2p} = (2p)! \sum_{a \in \ell_0: |a| = 2p} \frac{N_a}{a!} \prod_{k \geq 1} \left( \frac{1}{\lambda_k - \tau} \right)^{a_k} = (2p)! \sum_{a \in \ell_0: |a| = 2p} \frac{N_a}{(2a)!} \prod_{k \geq 1} \left( \frac{1}{\lambda_k - \tau} \right)^{2a_k}.
\]

For any \(a \in \ell_0\), the product \(\prod_{k \geq 1} \left( \frac{1}{\lambda_k - \tau} \right)^{2a_k}\) only contains a finite number of non-trivial terms, hence it is well-defined in \([0, +\infty)\). Thus, the sum on the right-hand side above makes sense in
[0, +∞], all the terms being non-negative. By Lem. 3.3, for any \( a ∈ ℓ₀ \) we have:

\[
\frac{N_{2a}}{(2a)!} = \prod_{k \geq 1} \left( \sum_{(b_j) ∈ ℓ^m_{a_k}} \prod_{j=1}^{m_k} \prod_{c=0}^{b_j} \left( \frac{1}{c! (b_j - c)!} \right)^2 \right),
\]

which yields the result.

We conclude this section with the proof of Prop. 1.13.

**Proof of Prop. 1.13.** We already derived an almost sure expression of the randomized moments \((M_p^p)_{p \geq 1}\) in Cor. 3.4. In particular, we already proved that the odd moments vanish almost surely, which is the first point in Prop. 1.13.

Recall that, for any \( p \geq 1 \), the polynomials \( P_p \) and \( Q_p \) were introduced in Def. 1.9, and the coefficient \( A_p \) was defined in Def. 1.11. By Cor. 3.4, in order to prove the second point of Prop. 1.13, we only need to prove the following for any \( p \geq 1 \) and \( τ ∈ ℓ_\mathbb{R} \setminus \{λ_k \mid k \geq 1\} \): if \( S^2_τ < +∞ \) for any \( q \in \{1, \ldots, p\} \), then

\[
\sum_{a ∈ ℓ_0; |a| = p} \prod_{k \geq 1} \left( \frac{1}{λ_k - τ} \right)^{2a_k} \prod_{(b_j) ∈ ℓ^m_{a_k}} \prod_{j=1}^{m_k} \prod_{c=0}^{b_j} \left( \frac{1}{c! (b_j - c)!} \right)^2 = \frac{1}{p!} P_p \left( 2A_1 S^1_τ, \ldots, 2A_p S^p_τ \right).
\]

Indeed,

\[
\frac{1}{p!} P_p \left( 2A_1 S^1_τ, \ldots, 2A_p S^p_τ \right) = \sum_{a ∈ ℓ_p} (-1)^{p-|a|} \frac{a!}{a!} \prod_{q=1}^{p} (A_q S^q_τ)^{a_q}.
\]

Let \( X = (X_k)_{k \geq 1} \), for any \( p ∈ ℓ_\mathbb{N}^* \), we denote by \( F_p(X) \) the formal power series in infinitely many variables defined by:

\[
F_p(X) = \sum_{a ∈ ℓ_0; |a| = p} \left( \prod_{k \geq 1} X^{2a_k}_k \right) \prod_{k \geq 1} \left( \sum_{(b_j) ∈ ℓ^m_{a_k}} \prod_{j=1}^{m_k} \prod_{c=0}^{b_j} \left( \frac{1}{c! (b_j - c)!} \right)^2 \right).
\]

We also define \( F(X) = 1 + \sum_{p \geq 1} F_p(X) \). Note that, for all \( p \geq 1 \), \( F_p \) is the homogeneous part of total degree \( 2p \) of \( F \). In the following, we write that two formal power series in \((X_k)_{k \geq 1}\) are equal if, for any \((a_k)_{k \geq 1} ∈ ℓ_0\), the coefficients in front of the monomial \( \prod_{k \geq 1} X^{a_k}_k \) are equal. We have:

\[
F(X) = \sum_{a ∈ ℓ_0} \prod_{k \geq 1} \prod_{b_1 + \cdots + b_{m_k} = a_k} X^{2b_1}_k \prod_{j=1}^{m_k} \prod_{c=0}^{b_j} \left( \frac{1}{c! (b_j - c)!} \right)^2
\]

\[
= \prod_{k \geq 1} \sum_{a_k} \prod_{b_1 + \cdots + b_{m_k} = a_k} \prod_{j=1}^{m_k} \left( X^{2b_j}_k \sum_{c=0}^{b_j} \left( \frac{1}{c! (b_j - c)!} \right)^2 \right)
\]

\[
= \prod_{k \geq 1} \left( \sum_{b_1, \ldots, b_{m_k} ∈ ℓ^{m_k}} X^{2b_1}_k \sum_{c=0}^{b} \left( \frac{1}{c! (b - c)!} \right)^2 \right)^{m_k}
\]

\[
= \prod_{k \geq 1} \left( \sum_{p \geq 0} \frac{X^{2p}_{2k}}{(p!)^2} \right)^{2m_k}.
\]
Using Eq. (B.2) with $T = X^2$ and $Y_p = \frac{1}{p!}$ for any $p \geq 1$, we have:

$$\ln \left( 1 + \sum_{p \geq 1} \frac{X^{2p}}{[p!]^2} \right) = \sum_{q \geq 1} (-1)^{q-1} Q_q \left( \frac{1}{2}, \frac{1}{q} \right) X^{2q} = \sum_{q \geq 1} (-1)^{q-1} A_q X^{2q},$$

(3.4)

by the definition of the $(A_p)_{p \geq 1}$ (Def. 1.11). Then, using Eq. (B.1) with $T = 1$, we have:

$$F(X) = \exp \left( \sum_{k \geq 1} \frac{2m_k \ln (I_0(2X_k))}{k} \right)$$

$$= \exp \left( \sum_{q \geq 1} (-1)^{q-1} A_q \sum_{k \geq 1} m_k X_k^{2q} \right)$$

$$= 1 + \sum_{p \geq 1} \frac{1}{p!} P_p \left( 2A_1 \sum_{k \geq 1} m_k X_k^2, \ldots, 2A_p \sum_{k \geq 1} m_k X_k^{2p} \right).$$

Let $p \in \mathbb{N}^*$, by definition of $P_p$ (see Def. 1.9), $P_p \left( 2A_1 \sum_{k \geq 1} m_k X_k^2, \ldots, 2A_p \sum_{k \geq 1} m_k X_k^{2p} \right)$ is homogeneous of total degree $2p$ in $X$. Hence,

$$F_p(X) = \frac{1}{p!} P_p \left( 2A_1 \sum_{k \geq 1} m_k X_k^2, \ldots, 2A_p \sum_{k \geq 1} m_k X_k^{2p} \right).$$

(3.5)

Let $\tau \in \mathbb{R} \setminus \{\lambda_k \mid k \geq 1\}$ and let us specialize Eq. (3.5) in the case where $X = \left( \frac{1}{\lambda_k - \tau} \right)_{k \geq 1}$. As we already explained (see the proof of Cor. 3.4), the left-hand side always makes sense in $[0, +\infty]$. However, since some of the coefficients of $P_p$ are negative, if two of the $(S_q^\tau)_{1 \leq q \leq p}$ are infinite, it might not be possible to make sense of the right-hand side of Eq. (3.5) evaluated on $\left( \frac{1}{\lambda_k - \tau} \right)_{k \geq 1}$.

Assuming that $S_q^\tau < +\infty$ for all $q \in \{1, \ldots, p\}$, we obtain precisely Eq. (3.3), which concludes the proof.

3.1.2 Case of the square torus

This section is concerned with the special case of the square flat torus $T = T_1$. The content of the other sections of this paper is, of course, still valid in this setting. Nonetheless, on $T$, the deterministic wave vectors sets $(\Lambda_k)_{k \geq 1}$ (see Eq. (2.1)) have additional symmetries. Namely, they are invariant by $(x_1, x_2) \mapsto (x_2, x_1)$, as explained in Rem. 2.1. In what follows, we define a variation on the model studied in the previous sections, such that the randomized $(\Lambda_k)_{k \geq 1}$ are also invariant by $(x_1, x_2) \mapsto (x_2, x_1)$. It turns out that the almost sure expression of the moments derived in Prop. 1.13 is still valid in this case.

This section follows step by step what we did in Step 2 of Sect. 1.2 and in Sect. 3.1.1. We assume that we are given an increasing sequence $(\lambda_k)_{k \geq 1}$ of positive numbers and a sequence $(n_k)_{k \geq 1}$ of positive integers. For any $k \geq 1$, $n_k$ will be the number of points in $\Lambda_k$ of the form $(x_1, x_2)$ with $0 \leq x_2 \leq x_1$.

**Definition 3.5.** Let $\eta'$ denote the product of the uniform probability measures on $[0, \frac{\pi}{4}]^{\mathbb{N}^* \times \mathbb{N}^*}$, that is the distribution of a sequence of independent uniform variables in $[0, \frac{\pi}{4}]$, indexed by $\mathbb{N}^* \times \mathbb{N}^*$.

**Definition 3.6.** Let $(\lambda_k)_{k \geq 1}$ be an increasing sequence of positive numbers, let $(n_k)_{k \geq 1}$ be a sequence of positive integers and let $(\theta_{k,j})_{k,j \geq 1}$ be a sequence of random variables in $[0, \frac{\pi}{4}]$ whose distribution is absolutely continuous with respect to $\eta'$. Then, for any $k \geq 1$, we set:

$$\Lambda_k = \sqrt{\lambda_k} \left\{ \zeta^{(i)}(\theta_{k,j}) \mid 1 \leq j \leq n_k, 1 \leq i \leq 8 \right\}.$$
where we denoted, for every $\theta \in [0, \frac{\pi}{4}]$:

$$\zeta^{(1)}(\theta) = (\cos(\theta), \sin(\theta)) = -\zeta^{(3)}(\theta), \quad \zeta^{(2)}(\theta) = (-\cos(\theta), \sin(\theta)) = -\zeta^{(4)}(\theta),$$

$$\zeta^{(5)}(\theta) = (\sin(\theta), \cos(\theta)) = -\zeta^{(7)}(\theta) \quad \text{and} \quad \zeta^{(6)}(\theta) = (-\sin(\theta), \cos(\theta)) = -\zeta^{(8)}(\theta).$$

For all $k \geq 1$, we denote by $r_k = \text{card}(\Lambda_k)$ and by $m_k$ the cardinality of $\Lambda_k \cap [0, +\infty)^2$. As in Sect. 3.1.1, almost surely, for any $k$ and $j \geq 1$, we have $\theta_{k,j} \in (0, \frac{\pi}{4})$, so that $r_k = 4m_k = 8n_k$.

Having defined the randomized $(\Lambda_k)_{k \geq 1}$ by Def. 3.6, we can define a random sequence of integers $(\mathcal{N}_{a})_{a \in \ell_{0}}$ by Def. 1.4. Then, for any $p \in \mathbb{N}^*$ and $\tau \in \mathbb{R} \setminus \{\lambda_k \mid k \geq 1\}$, we can still define the randomized moments $M_p^\tau$ as in Def. 3.2.

For our original random model, introduced in Sect. 1.2, the only thing we used in the proofs of Cor. 3.4 and Prop. 1.13 is the almost sure expression of the $(\mathcal{N}_{a})_{a \in \ell_{0}}$ derived in Lem. 3.3 (cf. Sect. 3.1.1). Our main point here is that Lem. 3.3 remains valid for the alternate random model introduced in this section. Thus, proceeding as in Sect. 3.1.1, Cor. 3.4 and Prop. 1.13 hold true in the model with additional symmetry, with the exact same proofs (recall that, almost surely, for all $k \geq 1$, $m_k = 2n_k$). In the next sections, we study the randomized moments $M_p^\tau$ using the almost sure expression derived in Prop. 1.13. In the case of the square torus, our results hold both for the general model of Sect. 1.2 and for the model with additional symmetry of Sect. 3.1.2.

We conclude this section by proving that Lem. 3.3 remains valid for the variation on our random model considered in this section.

**Proof of Lem. 3.3 for the alternate model of this section.** The proof follows the lines of the one we gave for the original model. For any $a \in \ell_{0}$, we have:

$$N_a = \text{card} \left\{ (i_{k,l}, j_{k,l}) \in \prod_{k \geq 1} (\{1, \ldots, 8\} \times \{1, \ldots, n_k\})^{a_k} \mid \sum_{k \geq 1} \sum_{l=1}^{a_k} \frac{\sqrt{\lambda_k}}{2\pi} \zeta^{(i_{k,l})}(\theta_{k,j_{k,l}}) = 0 \right\}.$$

Let $(i_{k,l}, j_{k,l}) \in \prod_{k \geq 1} (\{1, \ldots, 8\} \times \{1, \ldots, n_k\})^{a_k}$. For any $k \geq 1$, any $j \in \{1, \ldots, n_k\}$ and any $i \in \{1, \ldots, 8\}$, we set:

$$c_i(k, j) = \text{card} \{ l \in \{1, \ldots, a_k\} \mid (i_{k,l}, j_{k,l}) = (i, j) \}.$$

Then

$$\sum_{k \geq 1} \sum_{l=1}^{a_k} \frac{\sqrt{\lambda_k}}{2\pi} \zeta^{(i_{k,l})}(\theta_{k,j_{k,l}}) = \sum_{k \geq 1} \sum_{j=1}^{n_k} \frac{\sqrt{\lambda_k}}{2\pi} \left( (c_1(k, j) - c_2(k, j) - c_3(k, j) + c_4(k, j)) \cos(\theta_{k,j}) \right) \left( (c_1(k, j) + c_2(k, j) - c_3(k, j) - c_4(k, j)) \sin(\theta_{k,j}) \right)$$

$$+ \sum_{k \geq 1} \sum_{j=1}^{n_k} \frac{\sqrt{\lambda_k}}{2\pi} \left( (c_5(k, j) - c_6(k, j) - c_7(k, j) + c_8(k, j)) \sin(\theta_{k,j}) \right) \left( (c_5(k, j) + c_6(k, j) - c_7(k, j) - c_8(k, j)) \cos(\theta_{k,j}) \right).$$

If $(i_{k,l}, j_{k,l})_{k \geq 1, 1 \leq l \leq a_k}$ is such that for any $k \geq 1$ and any $j \in \{1, \ldots, n_k\}$ we have:

$$\begin{cases}
  c_1(k, j) - c_2(k, j) - c_3(k, j) + c_4(k, j) = 0, \\
  c_1(k, j) + c_2(k, j) - c_3(k, j) - c_4(k, j) = 0, \\
  c_5(k, j) - c_6(k, j) - c_7(k, j) + c_8(k, j) = 0, \\
  c_5(k, j) + c_6(k, j) - c_7(k, j) - c_8(k, j) = 0,
\end{cases} \tag{3.7}$$

then the above sum equals 0.

Conversely, let us assume that one of the relations (3.7) is not satisfied. Without loss of generality, we assume that there exists $k_1 \geq 1$ and $j_1 \in \{1, \ldots, n_{k_1}\}$ such that:

$$c_1(k_1, j_1) - c_2(k_1, j_1) - c_3(k_1, j_1) + c_4(k_1, j_1) \neq 0.$$
Let us denote by \((k_2, j_2), \ldots, (k_q, j_q)\) the other couples of the form \((k, j)\) with \(1 \leq j \leq n_k\) and such that there exists \(i \in \{1, \ldots, 8\}\) such that \(c_i(k, j) \neq 0\). If \(\sum_{k \geq 1} \sum_{i=1}^{n_k} \frac{\sqrt{2\pi}}{2\pi^c k} \zeta(i,1) (\theta_{k,j,k}) = 0\), then

\[
0 = \tilde{F}(\theta_1, \ldots, \theta_q) = \sum_{l=1}^{q} \frac{\sqrt{\lambda_{k,l}}}{2\pi} (c_1(k_1, j_1) - c_2(k_1, j_1) - c_3(k_1, j_1) + c_4(k_1, j_1)) \cos(\theta_l)
\]

\[
+ \sum_{l=1}^{q} \frac{\sqrt{\lambda_{k,l}}}{2\pi} (c_5(k_1, j_1) - c_6(k_1, j_1) - c_7(k_1, j_1) + c_8(k_1, j_1)) \sin(\theta_l),
\]

where we denoted \(\theta_l = \theta_{k,l,j}\) for any \(l \in \{1, \ldots, q\}\), and the previous equation defines \(\tilde{F}\). For any \((\theta_1, \ldots, \theta_q) \in (0, \pi)^q\), we have:

\[
\frac{\partial \tilde{F}}{\partial \theta_1}(\theta_1, \ldots, \theta_q) = -\frac{\sqrt{\lambda_{1,1}}}{2\pi} (c_1(k_1, j_1) - c_2(k_1, j_1) - c_3(k_1, j_1) + c_4(k_1, j_1)) \sin(\theta_1)
\]

\[
+ \frac{\sqrt{\lambda_{1,1}}}{2\pi} (c_5(k_1, j_1) - c_6(k_1, j_1) - c_7(k_1, j_1) + c_8(k_1, j_1)) \cos(\theta_1),
\]

and this quantity vanishes if and only if

\[
\tan(\theta_1) = \frac{c_5(k_1, j_1) - c_6(k_1, j_1) - c_7(k_1, j_1) + c_8(k_1, j_1)}{c_1(k_1, j_1) - c_2(k_1, j_1) - c_3(k_1, j_1) + c_4(k_1, j_1)}.
\]

Hence, \(\tilde{F}\) is a smooth submersion on

\[
\left\{ (\theta_1, \ldots, \theta_q) \in (0, \pi)^q \mid \theta_1 \neq \arctan \left( \frac{c_5(k_1, j_1) - c_6(k_1, j_1) - c_7(k_1, j_1) + c_8(k_1, j_1)}{c_1(k_1, j_1) - c_2(k_1, j_1) - c_3(k_1, j_1) + c_4(k_1, j_1)} \right) \right\},
\]

and \(\tilde{F}^{-1}(0) \subset [0, \frac{\pi}{4}]^q\) has measure 0 for the measure induced by \(\eta\'). Thus, if one of the relations \((3.7)\) is not satisfied, then almost surely, \(\sum_{k \geq 1} \sum_{i=1}^{n_k} \frac{\sqrt{2\pi}}{2\pi^c k} \zeta(i,1) (\theta_{k,j,k}) \neq 0\). This argument shows that, almost surely, for any \(a \in \ell_0\), we have:

\[
N_a = \text{card} \{ (i_{k,l}, j_{k,l})_{k \geq 1, 1 \leq l \leq n_k} \mid \forall k \geq 1, \forall j \in \{1, \ldots, n_k\}, \{c_i(k, j)\}_{1 \leq i \leq 8} \text{ satisfies } (3.7) \}
\]

Let us consider only the full-measure set on which the \(N_a\)s are defined by the previous formula. Let \(a = (a_k)_{k \geq 1} \in \ell_0\) and let \((i_{k,l}, j_{k,l})_{(k,l)} \in \prod_{k \geq 1} \{\{1, \ldots, 8\} \times \{1, \ldots, n_k\}\}^{a_k}\). For any \(k \geq 1\) and \(j \in \{1, \ldots, n_k\}\), we set:

\[
b_{k,j} = \text{card} \{ l \in \{1, \ldots, a_k\} \mid j_{k,l} = j \}.
\]

Then, \((i_{k,l}, j_{k,l})_{k \geq 1, 1 \leq l \leq a_k}\) satisfies Eq. \((3.7)\) for any \((k, j)\) if and only if:

\[
\begin{align*}
c_1(k, j) &= c_3(k, j), \\
c_2(k, j) &= c_4(k, j), \\
c_5(k, j) &= c_7(k, j), \\
c_6(k, j) &= c_8(k, j), \\
2(c_1(k, j) + c_2(k, j) + c_5(k, j) + c_6(k, j)) &= b_{k,j}.
\end{align*}
\]

Arguing as in the proof of Lem. 3.3, we deduce the following. If there exists \(k \geq 1\) such that \(a_k\) is odd, then \(N_a = 0\). And if \(a_k\) is even for any \(k \geq 1\), then

\[
N_a = a! \sum_{(b_{k,j}) \in \prod_{k \geq 1} n_k^a} \frac{1}{2 \sum_{j=1}^{a_k} b_{k,j} = a_k} \left( c_1(k, j) + c_2(k, j) + c_6(k, j) \right) \left( c_3(k, j) + c_4(k, j) \right) \prod_{k \geq 1} \prod_{j=1}^{n_k} \left( \frac{1}{c_1(k, j) + c_2(k, j) + c_6(k, j) + c_3(k, j) + c_4(k, j)} \right)^2
\]

\[
= a! \sum_{(b_{k,j}) \in \prod_{k \geq 1} n_k^a} \frac{1}{2 \sum_{j=1}^{a_k} b_{k,j} = a_k} \prod_{k \geq 1} \prod_{j=1}^{n_k} \sum_{c_1, c_2, c_3, c_4 \in \mathbb{N}} \frac{1}{c_1 + c_2 + c_6 + c_3 + c_4} \left( \frac{1}{c_1 + c_2 + c_6 + c_3 + c_4} \right)^2,
\]

22
Then, for any \( b \in \mathbb{N} \), we have:

\[
\sum_{c_1+c_2+c_3+c_4=b} \left( \frac{1}{c_1!c_2!c_3!c_4!} \right)^2 = \sum_{b'+b''=b} \left( \sum_{c_1+c_2=c'} \left( \frac{1}{c_1!c_2!} \right)^2 \right) \left( \sum_{c_3+c_4=c''} \left( \frac{1}{c_3!c_4!} \right)^2 \right)
\]

\[
= \sum_{b'+b''=b} \left( \sum_{c=0}^{b'} \frac{1}{c!(b'-c)!} \right)^2 \left( \sum_{c=0}^{b''} \frac{1}{c!(b''-c)!} \right)^2 .
\]

Finally, if \( a_k \) is even for any \( k \geq 1 \), we have:

\[
N_a = a! \sum_{(b_{k,j}) \in \mathbb{N}^n} \prod_{j=1}^{n_k} b_{k,j} \sum_{\prod_{j=1}^{n_k} b_{k,j}=a_k} \left( \sum_{k \geq 1} b_{k,j} \right)^2 \left( \sum_{c=0}^{b_{k,j}} \frac{1}{c!(b_{k,j}-c)!} \right)^2 \left( \sum_{c=0}^{b_{k,j}} \frac{1}{c!(b_{k,j}-c)!} \right)^2
\]

\[
= a! \sum_{(b_{k,j}) \in \mathbb{N}^n} \prod_{j=1}^{n_k} b_{k,j} \left( \sum_{k \geq 1} b_{k,j} \right)^2 \left( \sum_{c=0}^{b_{k,j}} \frac{1}{c!(b_{k,j}-c)!} \right)^2 \left( \sum_{c=0}^{b_{k,j}} \frac{1}{c!(b_{k,j}-c)!} \right)^2
\]

Recalling that \( m_k = 2n_k \) for all \( k \geq 1 \), \( N_a \) can be rewritten as:

\[
N_a = a! \sum_{(b_{k,j}) \in \mathbb{N}^n} \prod_{j=1}^{n_k} b_{k,j} \left( \sum_{k \geq 1} b_{k,j} \right)^2 \left( \sum_{c=0}^{b_{k,j}} \frac{1}{c!(b_{k,j}-c)!} \right)^2 ,
\]

which concludes the proof.

\[\square\]

### 3.2 Randomization of the spectrum of the Laplacian

In this section, we finally replace the sequence of eigenvalues of the Laplacian on \( \mathbb{T}_n \) by the values of a Poisson point process. This corresponds to the last step in the definition of our random model (Step 3 in Sect. 1.2). Then, we check that the resulting random sequence \( (\lambda_k)_{k \geq 1} \) behaves nicely, and we define the corresponding randomized even moments.

Let us consider a multiplicity function \( m : [0, +\infty) \to [1, +\infty) \) (cf. Def. 1.16) and denote by \( \nu_m \) the corresponding intensity measure (see Def. 1.17). From now on, we denote by \( (\lambda_k)_{k \geq 1} \) the increasing sequence of the values of a Poisson point process of intensity \( \nu_m \) on \( [0, +\infty) \), as in Def. 1.18. The fact that this definition makes sense is the content of Lem. A.2. Let us denote by \( m_k = m(\lambda_k) \) for all \( k \geq 1 \), as in Def. 1.18. As explained in Sect. 1.2, for any \( \tau \in \mathbb{R} \), we define the randomized spectral sums \( (S^p_\tau)_{p \geq 1} \) by Def. 1.12. Recalling, Prop. 1.13, we are now only interested in even order moments, and we can redefine the even order randomized moments \( (M^{2p}_\tau)_{p \geq 1} \) as follows.

**Definition 3.7.** Let \( m \) be a multiplicity function and let \( (\lambda_k)_{k \geq 1} \) be the associated randomized spectrum (see Def. 1.18). For any \( k \geq 1 \), let \( m_k = m(\lambda_k) \). For all \( p \in \mathbb{N}^* \), for all \( \tau \in \mathbb{R} \), we define the randomized even moment \( M^{2p}_\tau \) by:

\[
M^{2p}_\tau = (2p)! \sum_{a \in \mathcal{P}(p)} (-1)^{p-a} \left( \frac{1}{2} \right)^{|a|} \prod_{q=1}^{p} \left( A_q S^p_\tau \right)^{n_q} ,
\]

where \( \mathcal{P}(p) \), \( (A_p)_{p \geq 1} \) and \( (S^p_\lambda)_{p \geq 1} \) are defined by Def. 1.8, Def. 1.11 and Def. 1.12 respectively.
We will prove, in Lem. B.8, that the coefficients \((A_p)_{p \geq 1}\) are positive. Hence, Def. 3.7 defines \(M^{2p}\) as a polynomial in \((S^1_p, \ldots, S^{2p}_p)\) with some negative coefficients. In this setting, the spectral sums \((S^p_p)_{p \geq 1}\) are random variables taking values in \([0, +\infty]\). In particular, Def. 3.7 might not make sense if several of these variables take the value \(+\infty\) simultaneously. Lem. 1.19 states that this happens with probability 0. Let us now prove this result.

**Proof of Lem. 1.19.** Let \(\tau \in \mathbb{R}\). For all \(p \in \mathbb{N}^\ast\), let us define the function \(g_p : t \mapsto \frac{m(t)}{(t-\tau)^p}\). We have \(S^p_p = \sum_{k \geq 1} g_p(\lambda_k)\). Since

\[
\int_0^{+\infty} \min(g_p(t), 1)\nu_m(dt) = \frac{1}{16\pi} \int_0^{+\infty} \min \left( \frac{1}{(t-\tau)^2}, \frac{1}{m(t)} \right) dt \\
\leq \int_0^{+\infty} \min \left( \frac{1}{(t-\tau)^2}, 1 \right) dt < +\infty,
\]

by Campbell’s Theorem (Thm. A.3), \(S^p_p\) is almost surely finite. Then, almost surely, \(S^p_p\) is finite for all \(p \geq 1\). By Def. 3.7, this implies that almost surely, \(M^{2p}\) is well-defined and finite for all \(p \geq 1\).

\(\Box\)

**Remark 3.8.** By Campbell’s Theorem, for any \(p \geq 1\) and \(\tau \geq 0\), \(E[S^p_p] = \frac{1}{16\pi} \int_0^{+\infty} \frac{dt}{(t-\tau)^2} = +\infty\).

### 3.3 Limit distribution of the spectral sums

In this section, we study the asymptotic distribution of the randomized spectral sums \((S^p_p)_{p \geq 1}\) (cf. Def. 1.12) in the setting described in the previous section (see also Sect. 1.2, Step 3). More precisely, we prove that, after a good rescaling, the finite-dimensional marginals of \((S^p_p)_{p \geq 1}\) converge in distribution as \(\tau \to +\infty\). We also describe the limit distribution.

First, we need the following basic result about multiplicity functions (see Def. 1.16). It will be useful in the proof of Lem. 3.11 and the proof of the Random Weyl Law in Sect. 4.

**Lemma 3.9.** Let \(m\) be a multiplicity function. Then \(m'\) is bounded. Moreover, there exists \(\alpha < 1\) such that \(m(t) = O(t^\alpha)\) as \(t \to +\infty\).

**Proof.** The function \(m'\) is continuous on \([0, +\infty)\) and \(m'(t) \to 0\) as \(t \to +\infty\). Hence \(|m'|\) admits a maximum on \([0, +\infty)\).

Let \(\beta > 0\) be such that \(m'(t) = O(t^{-\beta})\) as \(t \to +\infty\). Without loss of generality, we can assume that \(0 < \beta < 1\). Since \(m\) is a \(C^1\) function, we have \(m(t) = m(1) + \int_1^t m'(s) ds\) for all \(t \geq 0\). Then, as \(t \to +\infty\), we have:

\[
\int_1^t |m'(s)| ds = O \left( \int_1^t s^{-\beta} ds \right) = O(t^{1-\beta}).
\]

Setting \(\alpha = 1 - \beta \in (0, 1)\), we have \(m(t) = O(t^\alpha)\) as \(t \to +\infty\). \(\Box\)

**Definition 3.10.** Let \(p \in \mathbb{N}^\ast\), we denote by \(\psi\) be the function from \(\mathbb{R}^p\) to \(\mathbb{R}\) defined by:

\[
\psi : (x_1, \ldots, x_p) \mapsto \exp \left( -\frac{1}{16\pi} \int_{-\infty}^{+\infty} 1 - \exp \left( \sum_{q=1}^p \frac{x_q}{t^{2q}} \right) dt \right).
\]

**Lemma 3.11.** Let \(m\) be a multiplicity function, let \((\lambda_k)_{k \geq 1}\) denote the associated randomized spectrum (see Def. 1.18) and let \(m_k = m(\lambda_k)\) for all \(k \geq 1\). Let the randomized spectral sums \((S^p_p)_{p \geq 1}\) be defined by Def. 1.12. Let \(p \in \mathbb{N}^\ast\), we denote by \(S_r = (m(\tau)S^1_p, m(\tau)^3S^3_p, \ldots, m(\tau)^{2p-1}S^{2p-1}_p)\), for any \(\tau \geq 0\).

Then \(S_r \overset{\tau \to +\infty}{\longrightarrow} S\) in distribution, where \(S\) is a random vector in \(\mathbb{R}^p\) whose characteristic function is \(\psi\). In particular, the limit distribution does not depend on \(m\).

**Proof.** Let \(p \in \mathbb{N}^\ast\) and let \(\tau \geq 0\). Let us denote by \(\psi_\tau\) the characteristic function of \(S_\tau\) and let \(x = (x_1, \ldots, x_p) \in \mathbb{R}^p\). For any \(q \in \{1, \ldots, p\}\), let \(g_q : t \mapsto \frac{m(t)}{(t-\tau)^p}\). We have already seen (cf. the
proof of Lem. 1.19) that \( g_q \) satisfies the hypothesis of Campbell’s Theorem (Thm. A.3) and that \( S_q^s = \sum_{k \geq 1} g_q(\lambda_k) \). Hence, we have:

\[
\psi_r(x) = \mathbb{E} \left[ \exp \left( i \sum_{q=1}^{p} x_q m(\tau)^{2q-1} S_q^s \right) \right] = \exp \left( -I_r(x) \right),
\]

where

\[
I_r(x) = \int_{0}^{\infty} \left( 1 - \exp \left( i \sum_{q=1}^{p} x_q m(\tau)^{2q-1} \frac{m(t)}{(t-\tau)^{2q}} \right) \right) v_m(dt)
\]

\[
= \frac{1}{16\pi} \int_{-\tau}^{\infty} \left( 1 - \exp \left( i \sum_{q=1}^{p} x_q m(\tau)^{2q-1} \frac{m(\tau+t)}{m(t)} \right) \right) \frac{dt}{m(\tau+t)}
\]

\[
= \frac{1}{16\pi} \int_{-\tau}^{\infty} \left( 1 - \exp \left( i \frac{m(\tau+tm(\tau))}{m(\tau)} \sum_{q=1}^{p} x_q \frac{t^{2q}}{m(t)} \right) \right) \frac{m(\tau)}{m(\tau+tm(\tau))} dt.
\]

Given \( \tau \in \mathbb{R} \) and \( t \in \left[ -\frac{\tau}{m(\tau)}, +\infty \right) \), we have:

\[
\left| \frac{m(\tau+tm(\tau))}{m(\tau)} - 1 \right| = \frac{1}{m(\tau)} \int_{\tau}^{\tau+tm(\tau)} \left| m'(s) \right| ds \leq |t| \max \left\{ \left| m'(s) \right| \mid s \geq -|t| m(\tau) \right\}.
\]

Let \( t \in \mathbb{R} \), by Lem. 3.9 we have \( m(\tau) = o(\tau) \) so that \( -|t| m(\tau) \xrightarrow[\tau \to +\infty]{} +\infty \). By Def. 1.16, \( m'(t) \xrightarrow[t \to +\infty]{} 0 \). Hence, the maximum on the right-hand side of Eq. (3.8) goes to 0 as \( \tau \to +\infty \) and \( \frac{m(\tau+tm(\tau))}{m(\tau)} \xrightarrow[\tau \to +\infty]{} 1 \). Thus, for all \( t \in \mathbb{R}^* \),

\[
\left( 1 - \exp \left( i \frac{m(\tau+tm(\tau))}{m(\tau)} \sum_{q=1}^{p} x_q \frac{t^{2q}}{m(t)} \right) \right) \frac{m(\tau)}{m(\tau+tm(\tau))} \xrightarrow[\tau \to +\infty]{} 1 - \exp \left( i \sum_{q=1}^{p} x_q \frac{t^{2q}}{m(t)} \right).
\]

We need an integrable dominating function, in order to apply Lebesgue’s Dominated Convergence Theorem. By Lem. 3.9, \( m' \) is bounded. Let us denote by \( \|m'\| = \sup_{t \geq 0} \|m'(t)\| \). For any \( t \in \mathbb{R}^* \), if \( |t| \leq \frac{1}{2\|m'\|} \), we have \( \left| \frac{m(\tau+tm(\tau))}{m(\tau)} - 1 \right| \leq \frac{1}{2} \) by Eq. (3.8). Then \( \frac{m(\tau+tm(\tau))}{m(\tau)} \geq \frac{1}{2} \) and

\[
\left( 1 - \exp \left( i \frac{m(\tau+tm(\tau))}{m(\tau)} \sum_{q=1}^{p} x_q \frac{t^{2q}}{m(t)} \right) \right) \frac{m(\tau)}{m(\tau+tm(\tau))} \leq 4.
\]

If \( |t| \geq \frac{1}{2\|m'\|} \), we have:

\[
\left( 1 - \exp \left( i \frac{m(\tau+tm(\tau))}{m(\tau)} \sum_{q=1}^{p} x_q \frac{t^{2q}}{m(t)} \right) \right) \frac{m(\tau)}{m(\tau+tm(\tau))} \leq \sum_{q=1}^{p} \frac{x_q}{t^{2q}} \|
\]

where \( \|\cdot\| \) stands for the Euclidean norm of \( \mathbb{R}^p \). Thus, we can use the following dominating function:

\[
t \mapsto \begin{cases} 
\frac{\|x\|}{\sum_{q=1}^{p} \frac{1}{t^{2q}}}, & \text{if } |t| \geq \frac{1}{2\|m'\|} \\
4, & \text{otherwise}.
\end{cases}
\]

Hence, by Lebesgue’s Theorem, for any \( x \in \mathbb{R}^p \), we have:

\[
I_r(x) \xrightarrow[\tau \to +\infty]{} \frac{1}{16\pi} \int_{-\infty}^{+\infty} 1 - \exp \left( i \sum_{q=1}^{p} x_q \frac{t^{2q}}{m(t)} \right) dt,
\]
and \( \psi \) converges pointwise to \( \psi \) (see Def. 3.10).

Let \( x \in \mathbb{R}^p \) be such that \( \|x\| \leq 1 \). For any \( t \in \mathbb{R}^* \), we have:

\[
1 - \exp \left( i \sum_{q=1}^{p} \frac{x_q}{t^{2q}} \right) \leq \min \left( 2, \left| \sum_{q=1}^{p} \frac{x_q}{t^{2q}} \right| \right) \leq \min \left( 2, \|x\| \frac{1}{t^{2q}} \right) \leq \min \left( 2, \sum_{q=1}^{p} \frac{1}{t^{2q}} \right).
\]

The function \( t \mapsto \min \left( 2, \sum_{q=1}^{p} \frac{1}{t^{2q}} \right) \) is integrable. Hence, by Lebesgue’s Theorem,

\[
\int_{-\infty}^{+\infty} 1 - \exp \left( i \sum_{q=1}^{p} \frac{x_q}{t^{2q}} \right) dt \xrightarrow{\, x \to 0 \,} 0
\]

and \( \psi(x) \xrightarrow{\, x \to 0 \,} 1 = \psi(0) \). Since \( \psi \) is continuous at 0, by Lévy’s Continuity Theorem, \( \psi \) is the characteristic function of a probability distribution. Moreover, denoting by \( S \) a random vector in \( \mathbb{R}^p \) whose characteristic function is \( \psi \), we have \( S \xrightarrow{\, \tau \to +\infty \,} S \) in distribution.

**Lemma 3.12.** Let \( p \in \mathbb{N}^* \) and let \( S = (S^1, \ldots, S^p) \) be a random vector in \( \mathbb{R}^p \) whose characteristic function is \( \psi \) (cf. Def. 3.10). Then, \( S \) admits a smooth density \( D \) with respect to the Lebesgue measure of \( \mathbb{R}^p \). The map \( D \) is the inverse Fourier transform of \( \psi \). Moreover, \( S \) is supported in:

\[
\Omega = \left\{ (x_1, \ldots, x_p) \in \mathbb{R}^p \mid x_1 \geq 0 \text{ and } \forall q \in \{2, \ldots, p\}, \ 0 \leq x_q < x_1x_{q-1} \right\}.
\]

**Proof.** By Lem. B.1, the function \( \psi \) is fast decreasing. Hence, its inverse Fourier transform is well-defined and smooth. Denoting by \( D \) this function, the distribution of \( S \) admits the density \( D \) with respect to the Lebesgue measure.

By Lem. 3.11, the random vector \( S \) is the limit of \( (m(\tau)S^1, m(\tau)^3S^2, \ldots, m(\tau)^{2p-1}S^p) \) in distribution, where \( m \) is any multiplicity function. Choosing \( m \) to be the constant unit function, we have:

\[
(S^1, \ldots, S^p) = \left( \sum_{k \geq 1} \frac{1}{(\lambda_k - \tau)^2}, \ldots, \sum_{k \geq 1} \frac{1}{(\lambda_k - \tau)^{2p}} \right) \xrightarrow{\tau \to +\infty} S,
\]

in distribution, where \( (\lambda_k)_{k \geq 1} \) is a Poisson point process on \([0, +\infty)\) with constant intensity \( \frac{1}{\lambda_0} \).

For any \( \tau \in \mathbb{R} \) and any \( q \in \{1, \ldots, p\} \), we have \( S^q_\tau > 0 \). Moreover, if \( q \geq 2 \), then

\[
S^{q-1}_\tau = \sum_{k \neq 1} \frac{1}{(\lambda_k - \tau)^{2q} - 2(\lambda_1 - \tau)^q} \sum_{k \geq 1} \frac{1}{(\lambda_k - \tau)^{2q}} > S^q_\tau.
\]

Since \( S \) admits a density with respect to the Lebesgue measure, we have \( \mathbb{P}(S \in \partial\Omega) = 0 \). Hence,

\[
\mathbb{P} \left( S \in \Omega \right) = \lim_{\tau \to +\infty} \mathbb{P} \left( (S^1, \ldots, S^p) \in \Omega \right) = 1.
\]

Finally the support of \( S \) is included in the closed set \( \overline{\Omega} \).

**Remark 3.13.** Let \( p \in \mathbb{N}^* \) and let \( S = (S^1, \ldots, S^p) \) be a random vector in \( \mathbb{R}^p \) whose characteristic function is \( \psi \). Then for any \( q \in \{1, \ldots, p\} \), the characteristic function of \( S^q \) is

\[
\psi_q : x \mapsto \exp \left( -\frac{1}{16\pi} \int_{-\infty}^{+\infty} 1 - \exp \left( \frac{ix}{t^{2q}} \right) dt \right).
\]

For any \( x \in \mathbb{R}^p \), we have:

\[
\int_{-\infty}^{+\infty} 1 - \exp \left( \frac{ix}{t^{2q}} \right) dt = 2 \int_{0}^{+\infty} \exp \left( \frac{ix}{t^{2q}} \right) - 1 dt = \frac{|x|^{2q}}{q} \int_{0}^{+\infty} e^{\frac{ix}{t^{2q}}} - 1 \frac{1}{u^{1+\frac{1}{2q}}} du.
\]

By [16, p. 90], the integral on the right-hand side equals \( \exp \left( -\frac{1}{2} \frac{x^2}{4q} \right) \Gamma \left( 1 - \frac{1}{2q} \right) \Gamma \left( 1 - \frac{1}{4q} \right) \). Hence, denoting by \( c_q = \left( \frac{1}{2q} \cos \left( \frac{\pi}{2q} \right) \Gamma \left( 1 - \frac{1}{2q} \right) \right)^{2q} \), we have:

\[
\psi_q(x) = \exp \left( -c_q |x|^{2q} \frac{1}{1 - \frac{x^2}{|x|^2}} \right).
\]
This shows that $S^q$ follows a one-sided $\frac{1}{2q}$-stable law, more precisely the stable law of parameters $(\frac{1}{2q}, 1, c_q, 0)$. This distribution is known to admit a smooth density with respect to the Lebesgue measure, and to be supported in $[0, +\infty)$. For $q \geq 2$, to the best of our knowledge, no analytical expression of the density is known. For $q = 1$, this distribution coincides with the Lévy distribution of parameters $0$ and $\frac{1}{2q}$. In particular, its density is $t \mapsto \frac{1}{\sigma t} e^{-\frac{\sqrt{2} t}{\sigma}} \psi (t)$. Note also that the expectation of $S^q$ is infinite, for all $q \geq 1$.

**Lemma 3.14.** Let $p \in \mathbb{N}^*$ and let $S = (S^1, \ldots, S^p)$ be a random vector in $\mathbb{R}^p$ whose characteristic function is $\psi$ (cf. Def. 3.10). Then the random vector $S = \left( \frac{S^1}{(S^1)^p}, \ldots, \frac{S^p}{(S^p)^p} \right)$ admits a smooth density

$$
D : (y_2, \ldots, y_p) \mapsto \int_0^{+\infty} (x_1) \frac{d(x_1)}{(x_1)^p} - 1 D (x_1, y_2(x_1)^2, \ldots, y_p(x_1)^p) dx_1,
$$

(3.9)

with respect to the Lebesgue of $\mathbb{R}^{p-1}$, where $D$ is the inverse Fourier transform of $\psi$. Moreover, the support of $D$ is contained in the compact set:

$$
K = \left\{ (y_2, \ldots, y_p) \in \mathbb{R}^{p-1} \mid 0 \leq y_p \leq \ldots \leq y_2 \leq 1 \right\}.
$$

**Proof.** Let us denote by $\tilde{S} = \left( \frac{S^1}{(S^1)^p}, \ldots, \frac{S^p}{(S^p)^p} \right)$. By Lem. 3.12, the random vector $S$ admits the density $D$. In particular, $\mathbb{P}(S^1 = 0) = 0$, so that $\tilde{S}$ and $S$ are almost surely well-defined. Then, for any continuous bounded function $g : \mathbb{R}^p \to \mathbb{R}$, we have:

$$
\mathbb{E} \left[ g (\tilde{S}) \right] = \int_{x \in \mathbb{R}^p} g \left( x_1, \frac{x_2}{(x_1)^p}, \ldots, \frac{x_p}{(x_1)^p} \right) D(x_1, \ldots, x_p) dx
$$

$$
= \int_{(x_1, y_2, \ldots, y_p) \in \mathbb{R}^p} g (x_1, y_2(x_1)^2, \ldots, y_p(x_1)^p) |x_1| \frac{d(x_1)}{(x_1)^p} - 1 dx_1 dy_2 \cdots dy_p.
$$

Recalling that $D$ is smooth and supported in $[0, +\infty)^p$ (see Lem. 3.12), this shows that $\tilde{S}$ admits the smooth density $\tilde{D} : (x_1, y_2, \ldots, y_p) \mapsto (x_1) \frac{d(x_1)}{(x_1)^p} - 1 D (x_1, y_2(x_1)^2, \ldots, y_p(x_1)^p)$, with respect to the Lebesgue measure of $\mathbb{R}^p$. Since $\tilde{S} = (S^1, S)$, the random vector $S$ admits the density $D$ defined by Eq. (3.9).

It is not clear that Eq. (3.9) defines a smooth function. In order to prove this, note that $\tilde{D}$ is smooth, and that the characteristic function $\tilde{\psi}$ of $\tilde{S}$ is fast decreasing. Then, the characteristic function of $S$ is $\psi : (y_2, \ldots, y_p) \mapsto \tilde{\psi}(0, y_2, \ldots, y_p)$, which is also fast decreasing. Thus, $D$ is smooth.

Finally, by Lem. 3.12, the support of $S$ is contained in $K$. Hence, we have almost surely $S^1 \geq 0$ (in fact $S^1 > 0$) and $0 \leq S^q \leq S^{q-1} S^1$, for all $q \in \{2, \ldots, p\}$. Thus, almost surely, we have:

$$
0 \leq \frac{S^p}{(S^1)^p} \leq \frac{S^{p-1}}{(S^1)^{p-1}} \leq \cdots \leq \frac{S^2}{(S^1)^2} \leq 1,
$$

which proves that the support of $D$ is contained in $K$. □

### 3.4 Proof of Thm. 1.22

This section is concerned with the proof of our main result (Thm. 1.22). Let $m : [0, +\infty) \to [1, +\infty)$ be a multiplicity function and let $\nu_m$ be the associated intensity measure (see Def. 1.16 and 1.17). Let $(\lambda_k)_{k \geq 1}$ and $(m_k)_{k \geq 1}$ be as in Def. 1.18, that is $(\lambda_k)_{k \geq 1}$ is a Poisson point process of intensity $\nu_m$ and, for all $k \geq 1$, $m_k = m(\lambda_k)$. Let the randomized spectral sums $(S^p_\tau)_{p \geq 1}$ be defined by Def. 1.12. Finally, let the even randomized moments $(M^{2p}_\tau)_{p \geq 1}$ be defined by Def. 3.7. We have seen in Lem. 1.19 that these random variables are almost surely well-defined for all $\tau \in \mathbb{R}$.

Since Thm. 1.22 is concerned with the normalized moments, let us start by deriving an expression of these normalized moments. Note that, by Def. 1.9 and Def. 1.11, $A_1 = Q_1(1) = 1$. Besides, by Def. 3.7, for all $\tau \in \mathbb{R}$, $M^2_\tau = 4S^1_\tau$. 27
Recall that $(\mu_p)_{p\geq 1}$ denotes the sequence of moments of the standard Gaussian distribution (see Def. 1.21) and that the polynomials $(P_p)_{p\geq 1}$ are defined by Def. 1.9. Let $p \in \mathbb{N}^*$ and let $\tau \in \mathbb{R}$, by Def. 3.7, we have:

$$\frac{M_p^2}{(M_p^2)^p} = \frac{(2p)!}{(4S_p^2)^p} \sum_{\alpha \in P(p)} (-1)^{p-|\alpha|} \frac{2^{\alpha_1}}{\alpha_1!} \prod_{q=1}^p \left( A_q S_q^2 \right)^{\alpha_q} = \frac{(2p)!}{2^p p!} \sum_{\alpha \in \mathcal{P}(p)} (-1)^{p-|\alpha|} \frac{p!}{\alpha!} \prod_{q=1}^p \left( 2A_q S_q^2 \right)^{\alpha_q} = \mu_{2p} \frac{1}{P_p} \left( A_2 S_2^2, \ldots, A_q S_q^2 \right)_{2 \leq q \leq p}.
$$

In view of Lem. 3.11, we rewrite this expression in the following form:

$$\frac{M_p^2}{(M_p^2)^p} = \mu_{2p} \frac{\left( A_2 \frac{m(\tau)^2 S_2^2}{2} \ldots, A_q \frac{m(\tau)^{q-1} S_q^2}{(2)^{q-1} (S_1^2)^{q-1}} \right)_{2 \leq q \leq p}}{P_p},$$

(3.10)

**Definition 3.15.** Let $p \in \mathbb{N} \setminus \{0, 1\}$ and let $S = (S^1, \ldots, S^p)$ be a random vector in $\mathbb{R}^p$ whose characteristic function is $\psi$ (see Def. 3.10). Let $l \in (0, +\infty)$, we define the random vector $(R_2(l), \ldots, R_p(l))$ in $\mathbb{R}^{p-1}$ by:

$$(R_q(l))_{2 \leq q \leq p} = \left( P_q \left( A_2 \frac{S_2^2}{2} \ldots, A_q \frac{S_q^2}{(2)^{q-1} (S_1^2)^{q-1}} \right)_{2 \leq q \leq p} \right),$$

where $(P_p)_{p \geq 1}$ is defined by Def. 1.9 and $(A_p)_{p \geq 1}$ is defined by Def. 1.11. We also define the random vector $(R_2(+\infty), \ldots, R_p(+\infty))$ as being constant equal to $(1, \ldots, 1) \in \mathbb{R}^{p-1}$.

**Remark 3.16.** The distributions of the random vectors $((S^1, \ldots, S^p))_{p \geq 1}$ are compatible, in the sense that, if $1 \leq q \leq p$, then $(S^1, \ldots, S^q)$ is distributed as the first $q$ components of $(S^1, \ldots, S^p)$. Thus, if $l \in (0, +\infty]$ and $2 \leq q \leq p$, then $(R_2(l), \ldots, R_q(l))$ is distributed as the first $(q-1)$ components of $(R_2(l), \ldots, R_p(l))$. In particular, the distribution of $(R_2(l), \ldots, R_q(l))$ is uniquely defined.

The following lemma proves the convergence in distribution stated in Thm. 1.22. Note that the same proof also works to prove the result stated in Rem. 1.24, as $\tau \to +\infty$.

**Lemma 3.17.** Let $p \in \mathbb{N} \setminus \{0, 1\}$ and let $l \in (0, +\infty]$. Let $(\tau_n)_{n \in \mathbb{N}}$ be a sequence such that $\tau_n \overset{n \to +\infty}{\longrightarrow} +\infty$ and $m(\tau_n) \overset{n \to +\infty}{\longrightarrow} l$, then the following holds in distribution:

$$\left( \frac{M_2}{(M_2^2)^p} \right)_{n \to +\infty} \overset{(\tau \to +\infty)}{\longrightarrow} (\mu_4 R_2(l), \ldots, \mu_{2p} R_p(l)).$$

**Proof.** By Lem. 3.11, we have $(m(\tau) S_2^2, m(\tau)^3 S_3^2, \ldots, m(\tau)^{2p-1} S_p^2) \overset{\tau \to +\infty}{\longrightarrow} S$ in distribution, where $S = (S^1, \ldots, S^p)$ is a random vector of characteristic function $\psi$ (see Def. 3.10). Since $S$ admits a density (see Lem. 3.12), we have $S^1 \neq 0$ almost surely. Hence, by the Continuous Mapping Theorem, the following holds in distribution:

$$\left( \frac{m(\tau)^3 S_3^2}{(m(\tau) S_2^2)^2}, \ldots, \frac{m(\tau)^{2p-1} S_p^2}{(m(\tau) S_2^2)^{p-1}} \right) \overset{\tau \to +\infty}{\longrightarrow} \left( \frac{S^2}{(S_1^2)^2}, \ldots, \frac{S_p}{(S_1^2)^{p-1}} \right).$$

If $l \in (0, +\infty)$, by Eq. (3.10) and the Continuous Mapping Theorem, we have:

$$\left( \frac{M_2}{(M_2^2)^p} \right)_{2 \leq q \leq p} \overset{n \to +\infty}{\longrightarrow} \left( \mu_{2p} P_q \left( 1, \frac{A_2}{2l} \frac{S_2^2}{(S_1^2)^2}, \ldots, \frac{A_q}{(2)^{q-1} (S_1^2)^{q-1}} \frac{S_q^2}{(S_1^2)^{q-1}} \right) \right)_{2 \leq q \leq p}$$

in distribution. This yields the result, by definition of $(R_q(l))_{2 \leq q \leq p}$ (see Def. 3.15).
If $l = +\infty$, the same arguments shows that:

\[
\left( \frac{M_{2p}^{2q}}{(M_{2p}^{2p})^q} \right)_{2 \leq q \leq p} \xrightarrow{n \to +\infty} (\mu_{2p}P_q(1, 0, \ldots, 0))_{2 \leq q \leq p}
\]

in distribution. By Def. 1.9, for all $q \geq 2$, $P_q(1, 0, \ldots, 0) = 1$. This concludes the proof, since $(R_{2q}(+\infty), R_{p}(+\infty)) = (1, \ldots, 1)$ by definition.

We have just proved the first part of Thm. 1.22. In order to conclude the proof, we need to study the distribution of the random vectors $(R_q(l))_{2 \leq q \leq p}$ defined by Def. 3.15. For $l = +\infty$, we have $(R_{2q}(l), \ldots, R_{p}(l)) = (1, \ldots, 1)$ by definition, for all $p \geq 2$. In this case, the limit distribution in Thm. 1.22 is a Dirac mass. Hence the convergence also holds in probability. When $l \in (0, +\infty)$, the following lemma proves that the limit distribution admit a smooth density. Note that this density is explicit.

**Lemma 3.18.** Let $p \in \mathbb{N} \setminus \{0, 1\}$, and let $D$ denote the function defined by Eq. (3.9). Then, for any $l \in (0, +\infty)$, the distribution of the random vector $(R_{2q}(l), \ldots, R_{p}(l))$ (see Def. 3.15) admits the smooth density

\[
D_l: (x_2, \ldots, x_p) \mapsto (2l)^{\frac{p-1}{2}} \prod_{q=2}^{p} \frac{1}{A_q q!} \mathcal{D} \left( \frac{2l}{A_2} Q_2(1, x_2), \ldots, \frac{(2l)^{p-1}}{A_p} Q_p(1, x_2, \ldots, x_p) \right)
\]

(3.11)

with respect to the Lebesgue measure of $\mathbb{R}^{p-1}$, where $(Q_q)_{q \geq 1}$ and $(A_p)_{p \geq 1}$ are defined by Def. 1.9 and Def. 1.11 respectively.

**Proof.** Let $(S^1, \ldots, S^p) \in \mathbb{R}^p$ be a random vector whose characteristic function is $\psi$ (see Def. 3.10). Let $g : \mathbb{R}^{p-1} \to \mathbb{R}$ be a continuous bounded function. By Def. 3.15, we have:

\[
E[g(R_{2q}(l), \ldots, R_{p}(l))] = \mathbb{E} \left[ g \left( P_2 \left( 1, \frac{A_2}{2l} \frac{S^2}{(S^1)^2} \right), \ldots, P_p \left( 1, \frac{A_p}{2l} \frac{S^p}{(S^1)^p} \right) \right) \right]
\]

\[
= \int_{y \in \mathbb{R}^{p-1}} g \circ \Phi'_p \left( \frac{A_2}{2l} y_2, \ldots, \frac{A_p}{2l} y_p \right) \mathcal{D}(y) \ dy,
\]

where $\mathcal{D}$ is the density of $\left( \frac{S^2}{(S^1)^2}, \ldots, \frac{S^p}{(S^1)^p} \right)$ (cf. Lem. 3.14) and $\Phi'_p$ is defined by Def. B.3. By Lem. B.8, we have $A_p > 0$ for all $p \geq 1$. Then,

\[
\int_{y \in \mathbb{R}^{p-1}} g \circ \Phi'_p \left( \frac{A_2}{2l} y_2, \ldots, \frac{A_p}{2l} y_p \right) \mathcal{D}(y) \ dy = \int_{y \in \mathbb{R}^{p-1}} g \left( \Phi'_p(y) \right) \mathcal{D} \left( \frac{2l}{A_2} y_2, \ldots, \frac{(2l)^{p-1}}{A_p} y_p \right) \frac{1}{\prod_{q=2}^{p} q!} \ dy
\]

\[
= \int_{x \in \mathbb{R}^{p-1}} g(x) \mathcal{D}_l(x) \ dx,
\]

where we obtained the last line by a change of variable $x = \Phi'_p(y)$. Indeed, by Cor. B.5, the map $\Phi'_p$ is a diffeomorphism of inverse $\Psi'_p$ (see Def. B.3), and its Jacobian determinant is $\prod_{q=2}^{p} q!$.

The last part of Thm. 1.22 is the content of the following lemma.

**Lemma 3.19.** Let $p \in \mathbb{N} \setminus \{0, 1\}$, then \{$(R_{2}(l), \ldots, R_{p}(l)) \mid l \in (0, +\infty)$\} is a one-parameter family of random vectors, whose distributions are pairwise distinct. That is, $(R_{2}(l), \ldots, R_{p}(l))$ and $(R_{2}(l'), \ldots, R_{p}(l'))$ have the same distribution if and only if $l = l'$.

**Proof.** Since $(R_{2q}(+\infty), \ldots, R_{p}(+\infty))$ is constant and $(R_{2q}(l), \ldots, R_{p}(l))$ is absolutely continuous with respect to Lebesgue for $l \in (0, +\infty)$, they cannot be equal in distribution. To conclude the proof, by Lem. 3.18, it is enough to prove that if $l$ and $l' \in (0, +\infty)$ are different, then $D_l \neq D_{l'}$, where these smooth functions are defined by Eq. (3.11).
By Lem. 3.14, the density $\mathcal{D}$ defined by Eq. (3.9) is smooth with compact support. Hence it admits a global maximum, that we denote by $M$. Since $\mathcal{D}$ is the density of a probability distribution, we have $M > 0$.

For any $l > 0$, the map:

$$(x_2, \ldots, x_p) \mapsto \left(\frac{2l}{A_2}Q_2(1, x_2), \ldots, \frac{(2l)^{p-1}}{A_p} Q_p(1, x_2, \ldots, x_p)\right)$$

is a global diffeomorphism from $\mathbb{R}^{p-1}$ to itself. Indeed, this map is the compose of $\Psi'_p$ (cf. Def. B.3) with $(x_2, \ldots, x_p) \mapsto \left(\frac{2l}{A_2}x_2, \ldots, \frac{(2l)^{p-1}}{A_p} x_p\right)$. The former is a diffeomorphism by Cor. B.5. Since $l > 0$, the latter is also a well-defined diffeomorphism from $\mathbb{R}^{p-1}$ to itself, by Lem. B.8. Hence, the density $\mathcal{D}_l$ defined by Eq. (3.11) admits a positive maximum, equal to $(2l)^{(p-1)} \left(\prod_{j=2}^{p} \frac{1}{2\pi} \right) M$.

Finally, if $l$ and $l' \in (0, +\infty)$ are different, then $\mathcal{D}_l$ and $\mathcal{D}_{l'}$ do not have the same global maximum. In particular, $\mathcal{D}_l \neq \mathcal{D}_{l'}$.

4 Random Weyl Law

In this section, we prove the Random Weyl Law (Prop. 1.25). Let $m : [0, +\infty) \to [1, +\infty)$ be a multiplicity function, in the sense of Def. 1.16. As in Sect. 2.1, we denote by $\nu_m$ the measure with density $(16m^3)^{-1}$ with respect to Lebesgue on $[0, +\infty)$ (cf. Def. 1.17). Let $(\lambda_k)_{k \geq 1}$ denote the increasing sequence of the values of a Poisson point process of intensity $\nu_m$. As in Def. 1.18, we denote $m_k = m(\lambda_k)$ for all $k \geq 1$.

The deterministic Weyl Law (Thm. 1.15) is concerned with the function $\mathcal{N}$ that counts the number of eigenvalues of $\Delta$ smaller than its argument, the eigenvalues being counted with multiplicity. With the notations of Sect. 2.1, for all $\lambda \geq 0$, we have:

$$\mathcal{N}(\lambda) = 1 + \sum_{\{k \geq 1 \mid \lambda_k \leq \lambda\}} \text{card}(\Lambda_k).$$

In our random model, recall that almost surely $\text{card}(\Lambda_k) = 4m_k$ for all $k \geq 1$. Hence, the random variable $\mathcal{N}_m(\lambda)$ defined by Eq. (1.5) is indeed the analogue of $\mathcal{N}(\lambda)$ in this model. Prop. 1.25 is the main reason behind our definition of the intensity measure $\nu_m$.

**Proof of Prop. 1.25.** Let $\lambda \geq 0$, we first compute the first two moments of $\mathcal{N}_m(\lambda)$. Note that

$$\mathcal{N}_m(\lambda) = 1 + \sum_{\{k \geq 1 \mid \lambda_k \leq \lambda\}} 4m_k = 1 + \sum_{k \geq 1} 4m(\lambda_k) \mathbf{1}_{[0, \lambda]}(\lambda_k),$$

where $\mathbf{1}_{[0, \lambda]}$ denotes the indicator function of $[0, \lambda]$. Applying Campbell’s Theorem (Thm. A.3) to the function $4m \mathbf{1}_{[0, \lambda]}$, we have:

$$\mathbb{E}[\mathcal{N}_m(\lambda)] = 1 + \mathbb{E} \left[ \sum_{k \geq 1} 4m(\lambda_k) \mathbf{1}_{[0, \lambda]}(\lambda_k) \right] = 1 + \int_0^\lambda 4m(t)\nu_m(dt) = 1 + \frac{\lambda}{4\pi},$$

and

$$\text{Var}(\mathcal{N}_m(\lambda)) = \text{Var} \left( \sum_{k \geq 1} 4m(\lambda_k) \mathbf{1}_{[0, \lambda]}(\lambda_k) \right) = \int_0^\lambda 16m(t)^2\nu_m(dt) = \frac{1}{\pi} \int_0^\lambda m(t) dt.$$

Let us now prove the Law of Large Numbers. By Lem. 3.9, there exists $\alpha < 1$ such that $m(t) = O(t^\alpha)$. Since $m(t) \geq 1$ for all $t \geq 0$, we must have $\alpha \geq 0$. Then

$$\text{Var}(\mathcal{N}_m(\lambda)) = \frac{1}{\pi} \int_0^\lambda m(t) dt = O \left( \int_0^\lambda t^\alpha dt \right) = O \left( \lambda^{\alpha+1} \right).$$

30
For all \( k \in \mathbb{N}^* \), we set \( t_k = k^{\gamma/k} \). We have \( t_k \to +\infty \) as \( k \to +\infty \), and

\[
\text{Var} \left( \frac{1}{t_k} \mathcal{N}_m(t_k) \right) = O \left( (t_k)^{\alpha-1} \right) = O(k^{-2}).
\]

Then,

\[
E \left[ \sum_{k \geq 1} \frac{1}{t_k^2} \left( \mathcal{N}_m(t_k) - \left( 1 + \frac{t_k}{4\pi} \right) \right)^2 \right] = \sum_{k \geq 1} \text{Var} \left( \frac{1}{t_k} \mathcal{N}_m(t_k) \right) < +\infty.
\]

Hence, \( \sum_{k \geq 1} \left( \frac{1}{t_k} \mathcal{N}_m(t_k) - \frac{1}{t_k} - \frac{1}{4\pi} \right)^2 < +\infty \) almost surely, which implies that almost surely \( \frac{1}{t_k} \mathcal{N}_m(t_k) \xrightarrow[k \to +\infty]{} \frac{1}{4\pi} \).

Let \( \lambda \geq 1 \), there exists a unique \( k \in \mathbb{N}^* \) such that \( t_k \leq \lambda < t_{k+1} \). Since \( \mathcal{N}_m \) is a non-decreasing function, we have:

\[
\frac{t_k}{t_{k+1}} \mathcal{N}_m(t_k) = \frac{\mathcal{N}_m(t_k)}{\lambda} \leq \frac{\mathcal{N}_m(\lambda)}{\lambda} \leq \frac{\mathcal{N}_m(t_{k+1})}{\lambda} \leq \frac{t_{k+1} \mathcal{N}_m(t_{k+1})}{t_k}.
\]

Then, since \( \frac{t_k}{t_{k+1}} \xrightarrow[k \to +\infty]{} 1 \) and \( k \sim \lambda^{\frac{\gamma}{\gamma-2}} \) as \( \lambda \to +\infty \), we have \( \frac{1}{t_k} \mathcal{N}_m(\lambda) \xrightarrow[\lambda \to +\infty]{} \frac{1}{4\pi} \) almost surely.

Let us denote by \( \sigma(\lambda) = \left( \frac{1}{4\pi} \int_0^\lambda m(t) dt \right)^{\frac{3}{2}} \). In order to prove the second claim, that is the Central Limit Theorem, it is enough to prove that the characteristic function \( \chi_\lambda \) of

\[
\frac{\mathcal{N}_m(\lambda) - E[\mathcal{N}_m(\lambda)]}{\text{Var}(\mathcal{N}_m(\lambda))^{\frac{1}{2}}} = \frac{\mathcal{N}_m(\lambda) - 1 - \frac{\lambda}{4\pi}}{\sigma(\lambda)}
\]

converges pointwise toward \( x \mapsto e^{-\frac{x^2}{2}} \), the characteristic function of a standard Gaussian variable. Since

\[
\int_0^{+\infty} \min(4m(t)1_{[0,\lambda]}(t), 1)\nu_m(dt) = \frac{1}{16\pi} \int_0^\lambda dt \leq \frac{\lambda}{16\pi} < +\infty,
\]

the characteristic function of \( \mathcal{N}_m(\lambda) - 1 \) is given by Campbell’s Theorem. For any \( x \in \mathbb{R} \), we have:

\[
\chi_\lambda(x) = \exp \left( -i x \frac{\lambda}{4\pi\sigma(\lambda)} \right) \mathbb{E} \left[ \exp \left( i x \frac{x}{\sigma(\lambda)} \sum_{k \geq 1} 4m(\lambda_k)1_{[0,\lambda]}(\lambda_k) \right) \right]
\]

\[
= \exp \left( - \int_0^\lambda \left( 1 - e^{ix\frac{\lambda}{4\pi\sigma(\lambda)}} \right) \nu_m(dt) - ix \frac{\lambda}{4\pi\sigma(\lambda)} \right)
\]

\[
= \exp \left( - \int_0^\lambda \left( 1 + \frac{4m(t)}{\sigma(\lambda)} - e^{ix\frac{\lambda}{4\pi\sigma(\lambda)}} \right) \nu_m(dt) \right).
\]

Hence, it enough to prove that, for all \( x \in \mathbb{R} \),

\[
\int_0^\lambda \left( 1 + i \frac{4m(t)}{\sigma(\lambda)} - e^{ix\frac{\lambda}{4\pi\sigma(\lambda)}} \right) \nu_m(dt) \xrightarrow[\lambda \to +\infty]{} \frac{x^2}{2}.
\]

Using the Taylor–Lagrange Formula for \( \theta \mapsto e^{i\theta} \) at order 2 around 0, we obtain that, for all \( t \in [0, \lambda] \),

\[
\left| 1 + i \frac{4m(t)}{\sigma(\lambda)} - \frac{1}{2} \left( \frac{4m(t)}{\sigma(\lambda)} \right)^2 - e^{ix\frac{\lambda}{4\pi\sigma(\lambda)}} \right| \leq \left| \frac{4m(t)}{\sigma(\lambda)} \right|^3.
\]

We have:

\[
\int_0^\lambda \left| \frac{4m(t)}{\sigma(\lambda)} \right|^3 \nu_m(dt) = \frac{4|x|^3}{\pi} \frac{1}{\sigma(\lambda)^3} \int_0^\lambda m(t)^2 dt.
\]

Since \( m \) is a multiplicity function, there exists \( \beta \in (0, 1) \) and \( C > 0 \) such that \( |m'(t)| \leq Ct^{-\beta} \), for all \( t \geq 0 \). In particular, \( m(t) = O(t^{1-\beta}) \), as in the proof of Lem. 3.9. Let \( s \) and \( t \in \left[ \lambda^\gamma, \lambda \right] \), we
have: $|m(t) - m(s)| \leq C |t - s| \lambda^{-\frac{2}{\beta}}$. Thus, if $|t - s| \leq \frac{1}{2\lambda^2} m(s) \lambda^{\frac{2}{\beta}}$, we have $m(t) \geq \frac{1}{2} m(s)$. Note that $m(s) \lambda^{\frac{2}{\beta}} = \lambda^{\frac{2}{\beta}} O(s^{1-\beta}) = O(\lambda^{1-\beta})$. Hence, for $\lambda$ large enough, for any $s \in [\lambda^{\frac{2}{\beta}}, \lambda]$, at least one half of the interval $[s - \frac{1}{2\lambda^2} m(s) \lambda^{\frac{2}{\beta}}, s + \frac{1}{2\lambda^2} m(s) \lambda^{\frac{2}{\beta}}]$ is contained in $[\lambda^{\frac{2}{\beta}}, \lambda]$ and

$$
\int_0^\lambda m(t) \, dt \geq \int_{\left[ s - \frac{1}{2\lambda^2} m(s) \lambda^{\frac{2}{\beta}}, s + \frac{1}{2\lambda^2} m(s) \lambda^{\frac{2}{\beta}} \right]} m(t) \, dt \geq \frac{m(s)^2}{4C} \lambda^{\frac{2}{\beta}}.
$$

Denoting by $M(\lambda)$ the maximum of $m$ on $[\lambda^{\frac{2}{\beta}}, \lambda]$, this yields $M(\lambda)^2 \leq 4C\pi \sigma(T)^2 \lambda^{-\frac{2}{\beta}}$, hence $M(\lambda) = o(\sigma(\lambda))$, as $\lambda \to +\infty$. Then,

$$
\int_{\lambda^{\frac{2}{\beta}}}^{\lambda} m(t)^2 \, dt \leq M(\lambda) \int_{\lambda^{\frac{2}{\beta}}}^{\lambda} m(t) \, dt \leq \pi M(\lambda) \sigma(\lambda)^2 = o(\sigma(\lambda)^3).
$$

On the other hand,

$$
\int_{\lambda^{1-\beta}}^{\lambda} m(t)^2 \, dt = O\left( \int_{\lambda^{1-\beta}}^{\lambda} t^{2-2\beta} \, dt \right) = O(\lambda^{\frac{2}{\beta} - 3\beta}) = o(\sigma(\lambda)^3).
$$

Indeed, since $m(t) \geq 1$ for all $t \geq 0$, we have $\sigma(\lambda) = \left( \frac{1}{\pi} \int_0^\lambda m(t) \, dt \right)^\frac{1}{2} \geq \sqrt{\frac{\lambda}{\pi}}$. Finally, we have:

$$
\frac{1}{\sigma(\lambda)^3} \int_0^\lambda m(t)^2 \, dt \xrightarrow[\lambda \to +\infty]{} 0.
$$

Thus, as $\lambda \to +\infty$,

$$
\int_0^\lambda \left( 1 + \frac{4xm(t)}{\sigma(\lambda)} - e^{\frac{4xm(t)}{\sigma(\lambda)}} \right) \nu_m(\lambda) \, dt = \frac{1}{2} \int_0^\lambda \left( \frac{4xm(t)}{\sigma(\lambda)} \right)^2 \nu_m(\lambda) \, dt + o(1)
$$

$$
= \frac{x^2}{2} + o(1). \quad \Box
$$

### A Reminder on Poisson point processes

In this section, we gather the few facts we need about Poisson point processes on $[0, +\infty)$. Apart from recalling the definition of these processes, we prove Lem. A.2, and we state Campbell’s Theorem (Thm. A.3), which is one of the key tools in the proof of our main results (Thm. 1.22 and Prop. 1.25).

We start with the definition of a Poisson point process in the setting we are interested in.

**Definition A.1.** Let $\nu$ denote a Borel measure on $[0, +\infty)$, a Poisson point process on $[0, +\infty)$ with intensity measure $\nu$ is a random subset $P$ of $[0, +\infty)$, whose distribution is characterized by the following properties.

- For any bounded Borel subset $B \subset [0, +\infty)$, the cardinality of $B \cap P$ is distributed as a Poisson variable of parameter $\nu(B)$.
- For any $n \in \mathbb{N}^*$, for any family $B_1, \ldots, B_n$ of disjoint bounded Borel subsets of $[0, +\infty)$, the random variables $\text{card}(B_1 \cap P), \ldots, \text{card}(B_n \cap P)$ are globally independent.

In the case, where the intensity measure is of the form $\nu_m$ (see Def. 1.17) for some multiplicity function $m : [0, +\infty) \to [1, +\infty)$ (see Def. 1.16), the elements of the Poisson point process $P$ form a nice sequence.

**Lemma A.2.** Let $m$ be a multiplicity function and let $\nu_m$ denote the associated intensity measure. Let $P$ be a Poisson point process on $[0, +\infty)$ of intensity $\nu_m$. Then, almost surely, the elements of $P$ can be ordered into an increasing sequence of positive numbers $(\lambda_k)_{k \geq 1}$ such that $\lambda_k \xrightarrow[k \to +\infty]{} +\infty$. 32
Proof. Let us denote by $P \subset [0, +\infty)$ the Poisson point process of intensity $\nu_m$. For any $\lambda \geq 0$, we have:

$$
\nu_m([0, \lambda]) = \frac{1}{16\pi} \int_0^\lambda \frac{dt}{m(t)} < +\infty.
$$

By Lem. 3.9, $m(t) \leq t$ for all $t$ large enough. Hence $t \rightarrow \frac{1}{m(t)}$ is not integrable at $+\infty$ and $\nu_m([0, \lambda]) \xrightarrow[\lambda \rightarrow +\infty]{} +\infty$. Let $n \in \mathbb{N}$, for all $\lambda \geq 0$ we have:

$$
\mathbb{P}(\text{card}(P) \leq n) \leq \mathbb{P}(\text{card}(P \cap [0, \lambda]) \leq n) = e^{-\nu_m([0, \lambda])} \sum_{k=0}^n \frac{\nu_m([0, \lambda])^k}{k!} \xrightarrow[\lambda \rightarrow +\infty]{} 0.
$$

Hence, for all $n \in \mathbb{N}$, $\mathbb{P}(\text{card}(P) \leq n) = 0$, and $P$ is almost surely infinite. Besides, almost surely, for any $\lambda \geq 0$, $\text{card}(P \cap [0, \lambda]) < +\infty$. Indeed,

$$
\{\exists \lambda > 0 \mid \text{card}(P \cap [0, \lambda]) = +\infty\} = \bigcup_{\lambda > 0} \{\text{card}(P \cap [0, \lambda]) = +\infty\},
$$

so that the probability of this event equals $\lim_{\lambda \rightarrow +\infty} \mathbb{P}(\text{card}(P \cap [0, \lambda]) = +\infty) = 0$. Thus, almost surely, $P$ is an infinite set whose elements can be ordered into an increasing sequence $(\lambda_k)_{k \geq 1}$ that goes to infinity as $k \rightarrow +\infty$. Finally, $\mathbb{P}(\lambda_1 = 0) \leq \mathbb{P}(P \cap \{0\} > 0) = 0$. Hence, almost surely $\lambda_1 > 0$, which ensures that $(\lambda_k)_{k \geq 1}$ is a sequence of positive numbers.

We conclude this section by recalling Campbell’s Theorem. The form of this theorem is the reason why we defined the sequence $(m_k)_{k \geq 1}$ as $(m(\lambda_k))_{k \geq 1}$ in our model. We state it in the special case we are interested in (compare [9, Sect. 3.2, pp. 28–31]).

**Theorem A.3** (Campbell). Let $(\lambda_k)_{k \geq 1}$ be the values of a Poisson point process on $[0, +\infty)$ with intensity measure $\nu$. Let $g : [0, +\infty) \rightarrow [0, +\infty)$ be a measurable function and let $S = \sum_{k \geq 1} g(\lambda_k)$. Then we have:

$$
\mathbb{E}[S] = \int_0^{+\infty} g(t)\nu(dt)
$$

in $[0, +\infty]$. If this quantity is finite, then the following holds in $[0, +\infty]$:

$$
\text{Var}(S) = \int_0^{+\infty} g(t)^2\nu(dt).
$$

Besides, $S$ is almost surely finite if and only if $\int_0^{+\infty} \min(g(t), 1)\nu(dt) < +\infty$.

Moreover, let $p \in \mathbb{N}^*$. For any $q \in \{1, \ldots, p\}$, let $g_q : [0, +\infty) \rightarrow [0, +\infty)$ be a measurable map such that $\int_0^{+\infty} \min(g_q(t), 1)\nu(dt) < +\infty$ and let $S^q = \sum_{k \geq 1} g_q(\lambda_k)$. Then, the characteristic function of $S = (S^1, \ldots, S^p)$ is given by:

$$
\forall(x_1, \ldots, x_p) \in \mathbb{R}^p, \quad \mathbb{E} \left[ \exp \left( i \sum_{q=1}^p x_q S^q \right) \right] = \exp \left( - \int_0^{+\infty} \left( 1 - \exp \left( i \sum_{q=1}^p x_q g_q(t) \right) \right) \nu(dt) \right).
$$

In particular, the integral on the right-hand side is well-defined for all $(x_1, \ldots, x_p) \in \mathbb{R}^p$.

**B Technical lemmas**

In this appendix, we gather the statements and proofs of several technical results that we used in the paper. In Sect. B.1, we prove that the function $\psi$ defined by Def. 3.10 is fast decreasing. Then, in Sect. B.2, we prove several results concerning the polynomials $(P_p)_{p \geq 1}$ and $(Q_q)_{q \geq 1}$ (see Def. 1.9). Finally, in Sect. B.3, we prove that the coefficients $(A_p)_{p \geq 1}$ are positive (see Def. 1.11).
B.1 Fast decreasing characteristic function

Lemma B.1. Let \( \psi : \mathbb{R}^p \to \mathbb{R} \) be the function defined by Def. 3.10. Their exists \( C > 0 \) such that \( |\psi(x)| = O \left( \exp \left(-C \|x\|^2 \right) \right) \), where \( \|\cdot\| \) stands for the canonical Euclidean norm of \( \mathbb{R}^p \).

**Proof.** Let \( x \in \mathbb{R}^p \), we have:

\[
|\psi(x)| = \exp \left( -\frac{1}{16\pi} \int_{-\infty}^{+\infty} \mathbb{R} \left( 1 - \exp \left( i \sum_{q=1}^{p} \frac{x_q}{t^2q} \right) \right) dt \right) = \exp \left( -\frac{1}{8\pi} I(x) \right),
\]

where

\[
I(x) = \int_{0}^{+\infty} \left( 1 - \cos \left( \sum_{q=1}^{p} \frac{x_q}{t^2q} \right) \right) dt.
\]

Let \( T(x) = \max \left\{ \left( \frac{2\pi}{3} |x_q| \right)^{\frac{1}{q}} \mid 1 \leq q \leq p \right\} \) and let \( q_0 \in \{1, \ldots, p\} \) be an index such that \( \left( \frac{2\pi}{3} |x_{q_0}| \right)^{\frac{1}{q_0}} = T(x) \). For all \( t \geq T(x) \), we have, for all \( q \in \{1, \ldots, p\} \), \( t^{2q} \geq T(x)^2 q \geq \frac{2\pi}{3} |x_q| \).

Hence,

\[
\left| \sum_{q=1}^{p} \frac{x_q}{t^2q} \right| \leq \sum_{q=1}^{p} \frac{|x_q|}{t^2q} \leq \frac{\pi}{2}.
\]

Recall that, for any \( u \in \mathbb{R} \), we have \( 1 - \cos(u) \geq 0 \). Moreover, for any \( u \in [0, \frac{\pi}{2}] \), we have:

\[
1 - \cos(u) = \int_{0}^{u} \sin(\theta) \, d\theta \geq \int_{0}^{u} \frac{2\theta}{\pi} \, d\theta = \frac{1}{\pi} u^2.
\]

Thus,

\[
I(x) \geq \int_{T(x)}^{+\infty} \left( 1 - \cos \left( \sum_{q=1}^{p} \frac{x_q}{t^2q} \right) \right) dt \geq \frac{1}{\pi} \int_{T(x)}^{+\infty} \left( \sum_{q=1}^{p} \frac{x_q}{t^2q} \right)^2 dt \geq \frac{1}{\pi} \sum_{1 \leq i,j \leq p} \frac{y_iy_j}{(2i + 2j - 1)T(x)^{2i+2j-1}}.
\]

Let \( B : \mathbb{R}^p \times \mathbb{R}^p \to \mathbb{R} \) be defined by \( B(y, z) = \sum_{1 \leq i,j \leq p} \frac{y_i y_j}{2i + 2j - 1} \). Then \( B \) is a bilinear symmetric form. Moreover, for any \( y \in \mathbb{R}^p \),

\[
B(y, y) = \sum_{1 \leq i,j \leq p} \frac{y_i y_j}{2i + 2j - 1} = \sum_{1 \leq i,j \leq p} y_i y_j \int_{1}^{+\infty} \frac{dt}{(2i+2j)^2} = \int_{1}^{+\infty} \left( \sum_{i=1}^{p} \frac{y_i}{2i} \right)^2 dt \geq 0.
\]

If \( B(y, y) = 0 \), then \( \frac{1}{2} \) is a root of the polynomial \( \sum_{i=1}^{p} y_i X^i \) for all \( t \geq 1 \), hence \( y = 0 \). Thus \( B \) is positive-definite and is a scalar product on \( \mathbb{R}^p \). The associated norm is then equivalent to the standard Euclidean norm on \( \mathbb{R}^p \). Therefore, there exists \( C' > 0 \) such that, for all \( y \in \mathbb{R}^p \), \( B(y, y) \geq C' \|y\|^2 \). Denoting by \( \bar{x} = \left( \frac{x_1}{|x_1|^2}, \ldots, \frac{x_p}{|x_p|^2} \right) \), we have:

\[
I(x) \geq \frac{T(x)}{\pi} B(\bar{x}, \bar{x}) \geq \frac{C'}{\pi} T(x) \left( \sum_{i=1}^{p} \left( \frac{x_i}{T(x)^{2i}} \right)^2 \right) \geq \frac{C'}{\pi} T(x) \left( \frac{|x_{q_0}|}{T(x)^{2q_0}} \right)^2 \geq \frac{C' \pi}{4p^2} T(x).
\]

Besides, since \( \sum_{q=1}^{p} x_q^2 = \|x\|^2 \), there exists \( q \in \{1, \ldots, p\} \) such that \( |x_q| \geq \frac{1}{p} \|x\| \). Then, we have \( T(x) \geq \left( \frac{2\pi}{3} |x_q| \right)^{\frac{1}{q_0}} \geq \left( \frac{1}{3p} \|x\| \right)^{\frac{1}{q_0}} \). Finally, there exists \( C > 0 \) such that, for any \( x \in \mathbb{R}^p \), we have\( \frac{1}{8\pi} I(x) \geq C \|x\|^2 \). Hence the result. \( \square \)

B.2 Polynomial maps

In this section, we prove several results related with the polynomials \( (P_p)_{p \geq 1} \) and \( (Q_p)_{p \geq 1} \) defined by Def. 1.9.
Lemma B.2. For any $p \in \mathbb{N}^*$, we have the following relations in $\mathbb{R}[X_1, \ldots, X_p]$:

$$X_p = Q_p (P_1(X_1), \ldots, P_p(X_1, \ldots, X_p)),$$

$$X_p = P_p (Q_1(X_1), \ldots, Q_p(X_1, \ldots, X_p)).$$

Proof. Let us consider the following power series, that are related to the generating functions of the sequences $(P_p)_{p \geq 1}$ and $(Q_p)_{p \geq 1}$. These are formal power series in infinitely many variables: $T$ and $X = (X_k)_{k \geq 1}$ (resp. $T$ and $Y = (Y_k)_{k \geq 1}$). We have:

$$P(X, T) = 1 + \sum_{p \geq 1} P_p (X_1, \ldots, X_p) \frac{T^p}{p!}$$

$$= \sum_{p \geq 1} \sum_{\alpha \in P(p)} (-1)^{\alpha} |\alpha| T^p \frac{1}{\alpha!} \prod_{q \geq 1} (X_q)^{\alpha_q}$$

$$= \sum_{\alpha \in \mathbb{N}_0} \frac{1}{\alpha!} \prod_{q \geq 1} ((-1)^{|\alpha_q|} X_q T)^{\alpha_q}$$

$$= \sum_{d \geq 0} \sum_{\alpha \in \mathbb{N}_0 : |\alpha| = d} \frac{d!}{\alpha!} \prod_{q \geq 1} ((-1)^{|\alpha_q|} X_q T)^{\alpha_q}$$

$$= \exp \left( \sum_{q \geq 1} (-1)^{q-1} X_q T^q \right).$$

(B.1)

Similarly, we have:

$$Q(Y, T) = \sum_{q \geq 1} (-1)^{q-1} Q_q (Y_1, \ldots, Y_q) T^q$$

$$= \sum_{q \geq 1} \sum_{\alpha \in P(q)} (-1)^{|\alpha| - 1} |\alpha| \frac{1}{\alpha!} \prod_{p \geq 1} \left( \frac{Y_p T^p}{p!} \right)^{\alpha_p}$$

$$= \sum_{\alpha \in \mathbb{N}_0 \setminus \{0\}} \frac{(-1)^{||\alpha||-1}}{|\alpha|} \frac{1}{\alpha!} \prod_{p \geq 1} \left( \frac{Y_p T^p}{p!} \right)^{\alpha_p}$$

$$= \sum_{d \geq 1} \frac{(-1)^{d-1}}{d} \sum_{\alpha \in \mathbb{N}_0 : |\alpha| = d} \frac{d!}{\alpha!} \prod_{p \geq 1} \left( \frac{Y_p T^p}{p!} \right)^{\alpha_p}$$

$$= \ln \left( 1 + \sum_{p \geq 1} Y_p \frac{T^p}{p!} \right).$$

(B.2)

Starting from Eq. (B.1) above, we apply the logarithm and obtain:

$$\ln \left( 1 + \sum_{p \geq 1} P_p (X_1, \ldots, X_p) \frac{T^p}{p!} \right) = \sum_{q \geq 1} (-1)^{q-1} X_q T^q.$$

The left-hand side has the same form as the last term in Eq. (B.2), with $Y_p = P_p (X_1, \ldots, X_p)$ for all $p \geq 1$. Hence, we get:

$$\sum_{q \geq 1} (-1)^{q-1} X_q T^q = \sum_{q \geq 1} (-1)^{q-1} Q_q (P_1(X_1), \ldots, P_q (X_1, \ldots, X_p)) T^q.$$

Identifying the coefficients according to their degree in the variable $T$ proves that for any $p \geq 1$, $X_p = Q_p (P_1(X_1), \ldots, P_p (X_1, \ldots, X_p))$. The proof of the second claim is similar. Starting from Eq. (B.2), we apply the exponential and obtain:

$$\exp \left( \sum_{q \geq 1} (-1)^{q-1} Q_q (Y_1, \ldots, Y_q) T^q \right) = 1 + \sum_{p \geq 1} Y_p \frac{T^p}{p!}.$$

Using Eq. (B.1) with $X_p = Q_p (X_1, \ldots, X_p)$ for all $p \geq 1$, and identifying the coefficients according to their degree in $T$ yields the result.

$$\square$$
Definition B.3. Let $p \in \mathbb{N} \setminus \{0, 1\}$, we denote by $\Phi_p$ and $\Psi_p$ the polynomial maps from $\mathbb{R}^p$ to $\mathbb{R}^p$ defined by:

$$
\Phi_p : (x_1, x_2, \ldots, x_p) \mapsto (P_1(x_1), P_2(x_1, x_2), \ldots, P_p(x_1, x_2, \ldots, x_p)),
$$
$$
\Psi_p : (x_1, x_2, \ldots, x_p) \mapsto (Q_1(x_1), Q_2(x_1, x_2), \ldots, Q_p(x_1, x_2, \ldots, x_p)),
$$

where $(P_p)_{p \geq 1}$ and $(Q_p)_{p \geq 1}$ were defined by Def. 1.9. We also denote by $\Phi'_p$ and $\Psi'_p$ the polynomial maps from $\mathbb{R}^{p-1}$ to itself defined by:

$$
\Phi'_p : (y_2, \ldots, y_p) \mapsto (P_2(1, y_2), \ldots, P_p(1, y_2, \ldots, y_p)),
$$
$$
\Psi'_p : (y_2, \ldots, y_p) \mapsto (Q_2(1, y_2), \ldots, Q_p(1, y_2, \ldots, y_p)).
$$

Lemma B.4. Let $p \in \mathbb{N} \setminus \{0, 1\}$, then $\Phi_p$ and $\Psi_p$ are smooth diffeomorphisms from $\mathbb{R}^p$ onto itself, such that $\Psi_p = (\Phi_p)^{-1}$. Moreover, for any $x \in \mathbb{R}^p$, the absolute value of the determinant of the differential of $\Phi_p$ at the point $x$ is $|\det (d_x \Phi_p)| = \prod_{q=1}^p q!$.

Proof. Since $\Phi_p$ and $\Psi_p$ are polynomial maps, it is enough to check that $\Psi_p \circ \Phi_p = \text{Id} = \Phi_p \circ \Psi_p$ to prove the first claim. By Lem. B.2, for any $(x_1, x_2, \ldots, x_p) \in \mathbb{R}^p$ and any $q \in \{1, \ldots, p\}$, we have:

$$
Q_q (P_1(x_1), P_2(x_1, x_2), \ldots, P_q(x_1, x_2, \ldots, x_q)) = x_q.
$$

Hence, $\Psi_p \circ \Phi_p = \text{Id}$. Similarly, by Lem. B.2, for any $(x_1, x_2, \ldots, x_p) \in \mathbb{R}^p$ and any $q \in \{1, \ldots, p\}$, we have $P_q (Q_1(x_1), Q_2(x_1, x_2), \ldots, Q_q(x_1, x_2, \ldots, x_q)) = x_q$, so that $\Phi_p \circ \Psi_p = \text{Id}$.

Let $x \in \mathbb{R}^p$, the matrix of $d_x \Phi_p$ in the canonical basis of $\mathbb{R}^p$ equals $(\frac{\partial \Phi_p}{\partial x_j}(x))_{1 \leq i, j \leq p}$. By Def. 1.9, this matrix is lower triangular, and its diagonal coefficients are $((-1)^{q-1} q!)_{1 \leq q \leq p}$. Hence $|\det (d_x \Phi_p)| = \prod_{q=1}^p q!$.

Corollary B.5. Let $p \in \mathbb{N} \setminus \{0, 1\}$, then $\Phi'_p$ and $\Psi'_p$ are smooth diffeomorphisms from $\mathbb{R}^{p-1}$ onto itself, such that $\Psi'_p = (\Phi'_p)^{-1}$. Moreover, for any $y \in \mathbb{R}^p$, we have $|\det (d_y \Phi'_p)| = \prod_{q=2}^p q!$.

Proof. By Lem. B.4, for any $y \in \mathbb{R}^{p-1}$, we have:

$$
(1, y) = \Phi_p \circ \Psi_p(1, y) = \Phi_p (1, \Psi_p(y)) = (1, \Phi'_p \circ \Psi'_p(y)).
$$

Hence, $\Phi'_p \circ \Psi'_p = \text{Id}$. Similarly, since $\Psi_p \circ \Phi_p = \text{Id}$, we have $\Phi'_p \circ \Psi'_p = \text{Id}$. Thus $\Psi'_p = (\Phi'_p)^{-1}$.

As in the proof of Lem. B.4 above, by Def. 1.9 the matrix of $d_y \Phi'_p$ is lower triangular and its diagonal coefficients are $(-2!, \ldots, (-1)^{p-1} p!)$. Hence $|\det (d_y \Phi'_p)| = \prod_{q=2}^p q!$.

B.3 Positivity of the coefficients $A_p$

In this final section, we prove the positivity of the coefficients $(A_p)_{p \geq 1}$, defined by Def. 1.11. The proof relies on the study of some modified Bessel functions. Let us denote by $I_0$ and $I_1$ the modified Bessel functions of the first kind of index 0 and 1 respectively. Recall that $I_0$ and $I_1$ are the entire functions defined by:

$$
I_0(X) = \sum_{p \geq 0} \frac{1}{(p!)^2} \left( \frac{X}{2} \right)^{2p} \quad \text{and} \quad I_1(X) = \sum_{p \geq 1} \frac{1}{(p-1)!p!} \left( \frac{X}{2} \right)^{2p-1} = I'_0(X).
$$

By Eq. (3.4), we have:

$$
\ln(I_0(2X)) = \sum_{p \geq 1} (-1)^{p-1} A_p X^{2p}.
$$

Our strategy is to study the power series $\ln(I_0(X))$ and deduce the positivity of the $(A_p)_{p \geq 1}$ from Eq. (B.3).
By [6, Eq. (2.2)], we have the following continued fraction expansion:

$$\frac{2 \, I_1(X)}{X \, I_0(X)} = \frac{1}{1 + \frac{1}{a_1 X^2} + \frac{1}{a_2 X^2} + \cdots}, \quad (B.4)$$

where $$a_k = \frac{1}{4k(k+1)}$$ for all $$k \geq 1$$. This type of continued fraction can be written as a so-called S-fraction, which was first studied by Stieltjes. By [18, Eq. (1.1)], we have:

$$\frac{1}{a_1 X^2} = Z + \frac{1}{a_2}, \quad (B.5)$$

where $$Z = X^{-2}$$ and we added a missing factor $$Z$$ on the right-hand side. Following Stieltjes, van Assche explains in [18, Thm. 1.1 and Eq. (1.5)] that the S-fraction converges and that we have:

$$\frac{1}{Z + \frac{a_1}{Z + \frac{a_2}{Z + \cdots}}} = \frac{s_0}{Z} + \sum_{k \geq 1} \frac{s_k}{Z + r_k}, \quad (B.6)$$

Here $$s_0 \geq 0$$ and $$(s_k)_{k \geq 1}$$ is a sequence of positive coefficients such that $$\sum_{k \geq 0} s_k = 1$$. Besides, $$(r_k)_{k \geq 1}$$ is a sequence of non-zero complex numbers such that $$r_k \to \infty$$ as $$k \to \infty$$.

**Lemma B.6.** Let $$(A_p)_{p \geq 1}$$ be defined by Def. 1.11 and the sequences $$(s_k)_{k \geq 1}$$ and $$(r_k)_{k \geq 1}$$ be those appearing in Eq. (B.6). We have $$A_1 = 1$$ and, for all $$p \geq 2$$, $$A_p = \frac{4}{p} \sum_{k \geq 1} s_k r_k^{p-1}$$.

**Proof.** Recalling that $$Z = X^{-2}$$, by Eq. (B.4), (B.5) and (B.6), we have:

$$\frac{2 \, I_1(X)}{X \, I_0(X)} = s_0 + \sum_{k \geq 1} \frac{s_k}{1 + r_k X^2},$$

Expanding the right-hand side, and using $$\sum_{k \geq 0} s_k = 1$$, we get:

$$\frac{2 \, I_1(X)}{X \, I_0(X)} = s_0 + \sum_{k \geq 1} s_k \sum_{p \geq 0} (-1)^p r_k^p X^{2p} = 1 + \sum_{p \geq 1} (-1)^p \left( \sum_{k \geq 1} s_k r_k^p \right) X^{2p}.$$

Then, taking the derivative of Eq. (B.3), we obtain:

$$\sum_{p \geq 1} (-1)^{p-1} (2p) A_p X^{2p-1} = 2 \frac{I_1(2X)}{I_0(2X)} = 2X + 2 \sum_{p \geq 2} (-1)^{p-1} \left( \sum_{k \geq 1} s_k r_k^{p-1} \right) 4^{p-1} X^{2p-1}.$$

The result follows by identifying the coefficients of these power series.

Since the $$(s_k)_{k \geq 1}$$ are positive, using Lem. B.6 it is enough to prove that the $$(r_k)_{k \geq 1}$$ are positive to obtain the positivity of the $$(A_p)_{p \geq 1}$$. This is what we do in the following.

As van Assche points out in [18], the convergents of the continued fraction on the left-hand side of Eq. (B.6) are of the form:

$$\frac{u_n \left( \frac{1}{2} \right)}{v_n \left( \frac{1}{2} \right)},$$

37
where \((u_n)_{n\geq 1}\) and \((v_n)_{n\geq 1}\) are sequences of polynomials such that, for all \(n \geq 1\), the zeros of \(v_n\) lie on the negative real half-line. Moreover, the continued fraction converges in the sense that \((u_n)\) and \((v_n)\) converge to entire functions \(u\) and \(v\) respectively, uniformly on compact sets. We have:

\[
\frac{u(z)}{v(z)} = \frac{s_0}{Z} + \sum_{k \geq 1} \frac{s_k}{Z + r_k},
\]

so that the zeros of \(v\) in \(\mathbb{C}^*\) are the complex numbers of the form \(-\frac{1}{r_k}\) with \(k \geq 1\). In particular, \(v \neq 0\), and its zeros are isolated points.

**Lemma B.7.** Let \(z \in \mathbb{C}\) be such that \(v(z) = 0\), then \(z\) is real and non-positive.

**Proof.** First, let us prove that \(v_n' \to v'\) uniformly on compact subsets of \(\mathbb{C}\). Let \(K\) be a compact subset of \(\mathbb{C}\). Let \(C\) be a closed contour such that \(K\) is contained in the interior of \(C\), and the distance from \(C\) to \(K\) is larger than 1. For all \(z \in K\), we have:

\[
|v_n'(z) - v'(z)| = \frac{1}{2\pi} \left| \int_C \frac{v_n(w) - v(w)}{(w - z)^2} \, dw \right| \leq \frac{1}{2\pi} \int_C |v_n(w) - v(w)| \, dw.
\]

Since \(C\) is compact, the right-hand side converges to 0 as \(n \to +\infty\).

Now, let us assume that there exists \(z \in \mathbb{C} \setminus (-\infty, 0]\) such that \(v(z) = 0\). For any \(R > 0\), we denote by \(C(R)\) the circle of center \(z\) and radius \(R\). Since \(v\) is analytic and non-zero, its zeros are isolated. Then, there exists \(R > 0\) such that \(C(R) \subset \mathbb{C} \setminus (-\infty, 0]\) and, \(\forall w \in C(R), v(w) \neq 0\).

The number of zeros of \(v_n\) lying inside \(C(R)\), counted with multiplicity, is given by the following contour integral:

\[
\frac{1}{2\pi i} \int_{C(R)} \frac{v_n'(z)}{v_n(z)} \, dz.
\]

This integral is well-defined and vanishes, because the zeros of \(v_n\) are real and negative. On the compact set \(C(R)\) we have \(v_n \to v\) and \(v_n' \to v'\) uniformly. Moreover, \(|v|\) is bounded from below. Hence, \(\frac{v_n'}{v_n}\) converges uniformly to \(\frac{v'}{v}\) on \(C(R)\) and:

\[
0 = \frac{1}{2\pi i} \int_{C(R)} \frac{v_n'(z)}{v_n(z)} \, dz \xrightarrow{n \to +\infty} \frac{1}{2\pi i} \int_{C(R)} \frac{v'(z)}{v(z)} \, dz > 0.
\]

This is absurd, which proves that the zeros of \(v\) must be real and non-positive. \(\square\)

**Lemma B.8.** For all \(p \geq 1\), \(A_p > 0\).

**Proof.** Let \((s_k)_{k \geq 1}\) and \((r_k)_{k \geq 1}\) be the sequences appearing in Eq. (B.6). For all \(k \geq 1\), we have \(v(-\frac{1}{r_k}) = 0\), hence \(-\frac{1}{r_k}\) is negative by Lem. B.7. Thus, both \((s_k)_{k \geq 1}\) and \((r_k)_{k \geq 1}\) are sequences of positive numbers. The result follows from the expression of the \((A_p)_{p \geq 1}\) derived in Lem. B.6. \(\square\)
