Abstract

In the nonextensive Tsallis scenario, Page’s conjecture for the average entropy of a subsystem [Phys. Rev. Lett. 71, 1291(1993)] as well as its demonstration are generalized, i.e., when a pure quantum system, whose Hilbert space dimension is \( mn \), is considered, the average Tsallis entropy of an \( m \)-dimensional subsystem is obtained. This demonstration is expected to be useful to study systems where the usual entropy does not give satisfactory results.

I. INTRODUCTION

Entropy is one of the most ubiquitous quantities in physics. For example, the entropy is fundamental in the study of quantum and classical information theories, applied in recent developments in telecommunications, computer science and engineering (for a review, see [1, 2]). In particular, a great effort has been made to understand quantum entanglement of inseparable quantum systems [3, 4]. A traditional example of a pure entangled state is the Einstein-Podolsky-Rosen singlet state [5].

Another interesting aspect is to obtain information about the entropy of a subsystem by studying its average [6, 7] over pure states of the big system, in unitary Haar measure. For instance, a complete pure system can be identified with a black hole and the radiation field related to it, in which case the subsystem is the black hole or alternatively the radiation field [8].

The standard entropy and its corresponding thermodynamics present serious difficulties when employed to study systems with long range interaction, in particular, when we deal with gravitational interactions [9, 10, 11, 12, 13]. A possible way to overcome this kind of difficulty is to investigate black hole radiation [8]; perhaps our generalized entropy, \( S(q) \), is to technically sneak up on ordinary entropy \( S \), yet avoiding its annoying logarithm by exploiting the \( q \to 1 \) limit. In any case, the aim of this work is to obtain the Tsallis entropy of a subsystem averaged over all pure states of the total system using unitary Haar measure to define our averaging. This result generalizes Page’s conjecture (a formula for that average of the usual entropy of a subsystem) and its subsequent demonstration [23, 24]. We note that Page’s conjecture for the average entropy of a subsystem has been applied to investigate black hole radiation [8]; perhaps our generalization can be useful to study parallel reductions to a subsystem in attempts to fit data with a Tsallis \( q \) distinct from 1.

To present our generalization, it is useful to first review Page’s work. This is performed in Sec. II. Sec. III is addressed to calculate the average Tsallis entropy of a subsystem. A summary is given in the last section.

II. AVERAGE ENTROPY OF A SUBSYSTEM

One way to get entropy out of a system in a pure quantum state is by a coarse graining of dividing the system into two subsystems and ignoring their correlations. Take
the system $AB$ with Hilbert space dimension $mn$ and normalized density matrix $\rho_{AB}$ and divide it into two subsystems $A$ and $B$, of dimensions $m$ and $n$ respectively. The entropy of system $A$ is $S_A = -\text{tr} \rho_A \ln \rho_A$, where the density matrix of the system $A$ is obtained by taking a partial trace over a total system, $\rho_A = \text{tr}_B \rho_{AB}$. In the same way, $S_B = -\text{tr} \rho_B \ln \rho_B$, with $\rho_B = \text{tr}_A \rho_{AB}$. If the system $AB$ is in a pure state, then $S_A = 0$ and $S_A = S_B$ as a consequence of the fact that $\rho_A$ and $\rho_B$ have the same set of nonzero eigenvalues. Unless the two systems are uncorrelated in the quantum sense ($\rho_{AB} = \rho_A \otimes \rho_B$, in which case $S_A = S_B = 0$), a full quantum analysis is necessary in order to obtain $S_A$ and $S_B$, which can be cumbersome. Yet it is sometimes easy to calculate the unitary Haar average entropy of the subsystem $A$ over all pure states of the total system, $S_{m,n} = \langle S_A \rangle$, and consequently also the average information of the subsystem, i.e., the deficit of average entropy from the maximum, $I_{m,n} = S_{m}^{\text{max}} - \langle S_A \rangle$, with $S_{m}^{\text{max}} = S(p_i = 1/m)$.

For $m \leq n$, Page showed that

$$S_{m,n} = \int S(p_i)P(p_1, \ldots, p_m)dp_1, \ldots, dp_m,$$

(3)

where $S(p_i) = -\sum_{i=1}^{m} p_i \ln p_i$, and $P(p_1, \ldots, p_m)$ is the probability distribution of the eigenvalues of $\rho_A$ for the random pure states $\rho_{AB}$ of the entire system [3, 4].

$$P(p_1, \ldots, p_m)dp_1 \ldots dp_m = N\delta \left(1 - \sum_{i=1}^{m} p_i\right) \prod_{1 \leq i < j \leq m} (p_i - p_j)^2 \prod_{k=1}^{m} p_k^{n-m} dp_k.$$

(4)

In Eq. (3), as well as in the following integrals, the integration limits is 0 and $\infty$. In the above equation, $N = 1/\int P(p_1, \ldots, p_m)dp_1, \ldots, dp_m$ is the normalization constant.

By using the identity $1 = (\int r^{mn}e^{-r}dr)/(mn \int r^{mn-1}e^{-r}dr)$ and the Polygamma function $\Psi(mn + 1) = (\int \ln r \ r^{mn}e^{-r}dr)/(mn \int r^{mn-1}e^{-r}dr)$, we can write Eq. (3) as

$$S_{m,n} = \frac{-m \int \ln r \ r^{mn} \sum_{i=1}^{m} p_i \ln p_i \ P(p_1, \ldots, p_m) \ dp_1, \ldots, dp_m \ dr}{mn \int \ r^{mn-1} \ P(p_1, \ldots, p_m) \ dp_1, \ldots, dp_m \ dr}$$

$$- \int \ln r \ r^{mn} \ P(p_1, \ldots, p_m) \ dp_1, \ldots, dp_m \ dr + \Psi(mn + 1).$$

(5)

Taking into account that $\sum p_i = 1$, we can introduce the new variables $x_i = r p_i$; then, by using the delta function to evaluate the integral in $r$, we obtain

$$S_{m,n} = \Psi(mn + 1) - \frac{\int S(x)|Q(x_1, \ldots, x_m)dx_1 \ldots dx_m}{mn \int |Q(x_1, \ldots, x_m)dx_1 \ldots dx_m},$$

(6)

with

$$Q(x_1, \ldots, x_m)dx_1 \ldots dx_m = \prod_{1 \leq i < j \leq m} (x_i - x_j)^2 \prod_{k=1}^{m} e^{-x_k} x_k^{n-m} dx_k.$$

(7)

Page conjectured [3], and other authors proved [28, 29], that the exact result is

$$S_{m,n} = \sum_{k=n+1}^{mn} \frac{1}{k} - \frac{m - 1}{2n}.$$  

(8)

Page had meanwhile applied this to calculate the information in black hole radiation [3]. It was considered a pure composite total state with a fixed dimension $mn$, composed by the black hole and the radiation. The radiation subsystem has dimension $m$ and the black hole one has dimension $n$. The average information in the smaller subsystem (for example if you have $1 \ll m \leq n$) is $I_r = S_{m}^{\text{max}} - \langle S_r \rangle \approx m/2n$. If furthermore $m \ll n$, the smaller subsystem is very nearly maximally mixed, and has very little information in it. The information increases for higher dimension of the smaller subsystem.

### III. AVERAGE TSALLIS ENTROPY

In this work, the above result is generalized to “the nonextensive case” as defined by replacing the usual entropy $[S(p_i)]$ in Eq. (3) by the Tsallis entropy $[S^{(q)}(p_i)]$. After similarly introducing the variables $x_i = r p_i$ in this generalization of Eq. (3), we obtain

$$S_{m,n}^{(q)} = \frac{1}{q - 1} - \frac{1}{q - 1} \Gamma(mn + q) J_{m,n}^{(q)},$$

(9)

where

$$J_{m,n}^{(q)} = \frac{\sum_{i=1}^{m} x_i^q |Q(x_1, \ldots, x_m)dx_1 \ldots dx_m}{\int Q(x_1, \ldots, x_m)dx_1 \ldots dx_m}.$$  

(10)

This expression can be written as a one-dimensional integral in terms of the one-point correlation function
of a Laguerre ensemble of complex Hermitian random matrices\textsuperscript{[31]}. By considering the symmetry of \(L_m(x)\) and the van der Monde determinant \(\Delta_m(x) = \prod_{i<j} (x_i - x_j)\), Eq. (10) reduces to

\[
J_{m,n}^{(q)} = \int dx_1 x_1^{q-1} \chi(x_1),
\]  

(11)

where

\[
\chi(x_1) = \frac{m!}{(n-1)!} x_1^{n-m} e^{-x_1} \left\{ [L_{m-1}^{n-m+1}(x_1)]^2 - L_m^{n-m+1}(x_1) L_m^{n-m+1}(x_1) \right\},
\]  

(13)

with a weight function \(\mu(x) = x^{n-m} e^{-x}\). This integration gives

\[
\chi(x_1) = m \int |\Delta_m(x)|^2 \prod_{k=1}^{m} \mu(x_k) \, dx_1 \ldots dx_m.
\]  

(12)

The remaining integration in \(J_{m,n}^{(q)}\), Eq. (11), can be evaluated by taking the following result\textsuperscript{[32]}:

\[
\int_0^\infty x^\theta e^{-x} L_r^\alpha(x) L_s^\beta(x) \, dx = \sum_{k=0}^{\min(r,s)} (-1)^{r+s} \left( \begin{array}{c} \theta - \alpha \\ r - k \end{array} \right) \left( \begin{array}{c} \theta - \beta \\ s - k \end{array} \right) \frac{\Gamma(\theta + k + 1)}{k!},
\]  

(14)

where \(\theta > -1\), \(\alpha\) and \(\beta\) are real parameters; and the brackets are binomial coefficients whose factorials of non-integers or integers \(\leq 0\) are interpreted through the usual \(z! = \Gamma(z + 1)\).

We finally get to our goal, a computationally explicit generalization of Page’s conjecture as well as its demonstration, \textit{i.e.},

\[
S_{m,n}^{(q)} = \frac{1}{q-1} - \frac{1}{q-1} \frac{\Gamma(m+1)\Gamma(mn)}{\Gamma(n)\Gamma(mn+q)} \sum_{k=0}^{\min(m,n)} \left( \begin{array}{c} q - 1 \\ m - 1 - k \end{array} \right) \frac{\Gamma(n - m + q + 1 + k)}{k!} - \sum_{k=0}^{m-2} \left( \begin{array}{c} q - 1 \\ m - 2 - k \end{array} \right) \left( \begin{array}{c} q - 1 \\ m - k \end{array} \right) \frac{\Gamma(n - m + q + 1 + k)}{k!},
\]  

(15)

for \(m \leq n\).

In the following, we discuss \(S_{m,n}^{(q)}\), mainly its dependence on \(q\). Note that Page’s result, Eq. (8), is recovered from \(S_{m,n}^{(q)}\) by taking the appropriate limit \((q \to 1)\), \textit{i.e.}, in this limit, Eq. (15) reduces to

\[
S_{m,n}^{(q=1)} = \Psi(mn + 1) - \frac{\Gamma(m+1)\Gamma(mn)}{\Gamma(n)\Gamma(mn+1)} \sum_{k=0}^{m-1} \frac{\Gamma(n - m + 2 + k)}{\Gamma(k - m + 2)!} \left[ 2\Psi(1) - 2\Psi(k - m + 2) + \Psi(n - m + 2 + k) \right] + \frac{\Gamma(m+1)\Gamma(mn)}{\Gamma(n)\Gamma(mn+1)} \sum_{k=0}^{m-2} \frac{\Gamma(n - m + 2 + k)}{\Gamma(m - k + 1)\Gamma(m - k + 1)\Gamma(m - k + 1)\Gamma(m - 3)k!} \times \left( 2\Psi(1) - \Psi(k - m + 1) - \Psi(3 - m + k) + \Psi(n - m + 2 + k) \right),
\]  

(16)

In the above equation, the only non-vanishing term in the summation is that one corresponding to \(k\) maximum, so that we obtain \(S_{m,n}^{(q=1)} = \Psi(mn + 1) - \Psi(n + 1) - (m - 1)/2n\). By using the relation \(\Psi(n + 1) = \sum_{k=0}^{n} 1/k - \gamma\), where \(\gamma\) is the Euler’s constant, we get Page’s results, Eq. (8).
Furthermore, as in the case \( q = 1 \), \( S_{mn}^{(q)} \) also assumes a simple form when \( q \) is a positive integer. This is a consequence of poles of the \( \Gamma(x) \) function for negative integers \( x \). Thus, in the cases of \( q = 2, 3, 4, \ldots \), Eq. (15) reduces to

\[
S_{mn}^{(q)} = \frac{1}{q-1} - \frac{1}{q-1} \frac{\Gamma(m+1)\Gamma(mn)}{\Gamma(mn+q)} \sum_{k=1}^{q-1} \left( \frac{\Gamma(q)}{\Gamma(k)\Gamma(q+1-k)} \right)^2 \frac{\Gamma(n+q+1-k)}{(m-k)!} \\
- \sum_{k=1}^{q-2} \left( \frac{\Gamma(q)}{\Gamma(k)\Gamma(q+1-k)} \right) \left( \frac{\Gamma(q)}{\Gamma(2+k)\Gamma(q-1-k)} \right) \frac{\Gamma(n+q-k)}{(m-1-k)!} .
\]

(17)

Note that the second sum only gives contribution for \( q = 3, 4, 5, \ldots \). In particular, for \( q = 2 \), the Tsallis entropy leads to the quadratic entropy. This entropy was firstly used in theoretical physics by Fermi (see p. 31, Eq. 2.11.3 of Ref. [33]). In this case, Eq. (17) reduces to

\[
S_{mn}^{(q=2)} = 1 - \frac{n+m}{mn+1} .
\]

(18)

If we observe that the maximum \( q \)-entropy, obtained when \( p_i = 1/m \), is given by \( S_{mn}^{(q=2)} = (1-m^{-q})/(q-1) \), the average information, \( I^{(q)}_{m,n} = S_{mn}^{(q=2)} - < S_{A}^{(q)} > \), for \( q = 2 \) is

\[
I^{(q=2)}_{m,n} = \left( 1 - \frac{1}{m} \right) - \left( 1 - \frac{m+n}{mn+1} \right) \approx \frac{1}{n} .
\]

(19)

for \( mn \gg 1 \). Observe that for \( mn \gg 1 \), \( I_{m,n}^{(q=2)} \) is a power law with only \( n \) dependence. Thus, for a system \( AB \) with fixed \( mn \) dimension, a log-log plot of \( I_{m,n}^{(q=2)} \) versus \( m \) gives a straight line.

For an arbitrary \( q \) value, Eq. (13) does not reduce to a simple form, so we show some graphs instead. For example, consider a total system with fixed Hilbert space dimension \( mn = 291600 \) (about the number of states very naively expected for a black hole near the Planck mass). In the case of a total pure state, we have \( < S_A^{(q)} > = < S_B^{(q)} > = S_{mn}^{(q)} \) if \( m \leq n \), and \( < S_A^{(q)} > = < S_B^{(q)} > = S_{n,m}^{(q)} \) if \( m \geq n \), where \( S_{mn}^{(q)} \) is given by Eq. (13) and \( S_{n,m}^{(q)} \) is obtained from it by performing the exchange \( m \leftrightarrow n \). In Fig. (1), we plot \( < S_A^{(q)} > \) for some representative \( q \) values. Fig. (2) shows the average information \( I_{m,n}^{(q)} \) to different \( q \) values.

**IV. SUMMARY**

Summing up, we have generalized Page’s conjecture and its demonstration in order to incorporate the nonextensive regime induced by the Tsallis entropy. Naturally, this result must and does reduce to the usual one in the limit \( q \to 1 \). For other representative \( q \) values and \( mn \) still fixed at 291600, average entropy and average information are log-log plotted, \( S^{(q)} \) versus \( m \) then \( S^{(q)} \) versus \( S_{mn}^{(q)} \) in Fig. (1), and \( I^{(q)} \) versus \( m \) then \( I^{(q)} \) versus \( S_{mn}^{(q)} \) in Fig. (2). The straightness shown by the triangles in Fig. (2a) illustrates the case \( q = 2 \) as a separation between two different regimes. In general, calculations based on the nonextensive Tsallis entropy have been addressed in the study of systems with long range interaction, spatiotemporal complexity, and fractal structure; thus, we hope our result may be useful for such systems.

More formal applications of the \( q \to 1 \) limit to derive
FIG. 2: a) Plot of $I^{(q)}_{m,n}$ versus $m$ to $q = 0.5$, $q = 1$, $q = 1.5$, $q = 2$ and $q = 2.5$ with $mn = 291600$. b) Plot of $I^{(q)}_{m,n}$ versus $S^{(q)}_{\text{max}}$ to $q = 0.8$, $q = 1$ and $q = 1.2$ with $mn = 291600$.

Pedron, and E. K. Lenzi, ordinary entropies, may also turn out feasible, for kinds of averaging other than Haar-unitary, in particular, for time averaging under Gaussian-distributed Hamiltonians which do not discriminate between $m$ system and $n$ system, and also for similar distributions which, instead, do discriminate so as to model approximate mutual isolation. In both cases, results for $q = 2$ are known and the $q \to 1$ limit would be welcome. Such further applications would be analogous to our demonstration in this present paper of Page’s conjecture, in being independent of the issue of whether the Tsallis entropy for $q \neq 1$ is or is not directly applicable to physical situations.
