Resident physicians’ perceptions of ambulatory care pharmacy

Ashley H. MEREDITH, Darin RAMSEY, Andrew SCHMELZ, Rachel BERGLUND

Abstract
Background: Physicians' acceptance of clinical pharmacy services is dependent on exposure to those services, with use increasing as resident physicians progress through their training. Resident physicians train within environments that have a multidisciplinary teaching and clinical care approach, working closely with other healthcare professionals. Ambulatory care pharmacists are increasingly working with resident physicians in clinic settings as part of the multidisciplinary team, and identification of resident physicians’ perceptions may influence future collaboration.

Objective: The objective of this research is to evaluate the perception of ambulatory care clinical pharmacy services from the perspective of resident physicians.

Methods: A statewide network of ambulatory care pharmacists was identified and received an electronic questionnaire. Pharmacists working within clinics that serve as training sites for resident physicians then completed and distributed questionnaires to the resident physicians within their clinical site. Items related to demographics and perception of involvement and interactions with clinical pharmacists.

Results: Forty-five resident physicians responded from four unique clinical sites (response rate = 42%). They agreed or strongly agreed that pharmacists help patients obtain their therapeutic goals (97.8%), are able to educate patients effectively (95.6%), provide high quality care (97.8%), and do a good job helping co-manage patients (91.1%). Previous exposure to pharmacists was limited primarily to the drugstore (48.9%) and hospital (51.1%) settings. Resident physicians in the third year of training and those reporting a friend was a pharmacist, were more likely to have a positive perception of the pharmacist’s role as a resident educator (p=0.048 and p=0.044, respectively).

Conclusions: Resident physicians with a longer duration of exposure and personal friendship with a pharmacist are more likely to express positive perceptions. Areas for further enhancements in this interprofessional relationship related to perceptions about pharmacist autonomy and patient relationships were identified.

INTRODUCTION
Ambulatory care clinical pharmacy practice has shown significant recent growth with increased numbers of pharmacists managing multiple disease states under collaborative drug therapy management protocols. In addition to preventative care, pharmacists may provide chronic disease management for a variety of conditions including the management of diabetes, hypertension, and dyslipidemia. Under Collaborative Practice Agreements (CPA) or Collaborative Drug Therapy Management (CDTM) protocols, prescribers can delegate aspects of patient care such as initiating, modifying, and discontinuing drug therapy. Pharmacists may also order and interpret any necessary laboratory tests as it pertains to the disease state(s) being monitored. Physicians’ acceptance of clinical pharmacy services is highly dependent on the level of exposure to those services and expectations of pharmacists are associated with the number of years post-graduation from medical school, with those physicians who graduated within the past ten years having higher expectations of pharmacists. Expectations include assisting in the design of drug therapy treatment plans, monitoring response to drug therapy, and patient education regarding safe and appropriate use of medications. Additionally, physicians that are young, group practice-oriented, and write higher numbers of prescriptions are more likely to utilize, and have a positive view toward, clinical pharmacy services.

A collaborative working relationship (CWR) is built in stages. In order for pharmacists to establish CPAs or CDTM protocols, the first step is to build strong working relationships with physicians. The Physician-Pharmacist Collaborative Instrument (PPCI) measures provider exchange characteristics through a framework consisting of five stages: Stage 0 - Professional Awareness, Stage 1 - Professional Recognition, Stage 2 - Exploration and Trial, Stage 3 - Professional Relationship Expansion, Stage 4 - Commitment to the Collaborative Working Relationship. As the relationship progresses through the various stages, the establishment of mutual trust and respect is established, ultimately strengthening the professional relationship to improve patient outcomes. While progressing to Stage 4 may take time to achieve, pharmacy residents may be more receptive to this collaboration as they become familiar with the pharmacist’s professional
abilities and have confidence in the benefits of the collaboration.

The Collaboration Among Pharmacists and Physicians To Improve Outcomes Now (CAPTION) trial evaluated a physician-pharmacist collaborative model for blood pressure management and found that pharmacists with direct patient care improve control of chronic conditions and should be members of the care team for patients with hypertension. The inclusion of pharmacists on the care team likely translates to the management of other chronic conditions, especially those related to cardiovascular disease.

Throughout clinical training, resident physicians are placed within environments that have a multidisciplinary teaching component requiring working closely with other healthcare professionals. As part of this multidisciplinary teaching approach, ambulatory care pharmacists often work with resident physicians in clinic settings. Approximately 25–50% of family practice residency programs report the presence of clinical pharmacists within their program, although limited data is available describing details of this practice setting. First-year resident physicians in family medicine programs that offer clinical pharmacy services have a more favorable attitude towards clinical pharmacist’s participation on the health care team compared to those residency programs that lack these services. In addition, these residents prefer to practice as part of a multidisciplinary team that includes a pharmacist and see the value in hiring a clinical pharmacist within a private practice setting. Resident physicians value the clinical pharmacist educator and thought their experiences with the pharmacist improved their quality of patient care, drug knowledge, and confidence. Lastly, the clinical pharmacist educator was found to positively impact resident physicians’ abilities to work as part of an interdisciplinary team.

Additional data show that use of clinical pharmacy services increases as resident physicians progress through their training programs. This is consistent with the CWR framework and existing literature on pharmacist-physician collaboration: development of mutual trust, sustaining the relationship, and understanding of one another’s role. Based on reporting of pharmacist-physician encounters, first- and second-year resident physicians do not fully utilize clinical pharmacy services, perhaps due to the lack of education and communication regarding the available services offered. Third-year resident physicians may utilize clinical pharmacy services more frequently due to increased patient contact, development of a professional relationship with the clinical pharmacist, and/or a better understanding of the importance for therapeutic information.

Currently, there has not been any literature identified that has assessed the role of ambulatory care pharmacists from the viewpoint of resident physicians. Due to the increasing presence of ambulatory care pharmacists as part of resident physician clinical training programs and sites, it is necessary to understand resident physicians’ awareness and perceptions of the capabilities of ambulatory care pharmacists. These physicians-in-training can impact future collaboration, patient care, and expansion of ambulatory care pharmacy. The purpose of this study is to evaluate the perception of ambulatory care clinical pharmacy services from the perspective of resident physicians in Indiana.

METHODS

In order to identify appropriate participants for this observational cohort study, a two-step recruitment strategy was utilized. The first step involved identifying pharmacists within clinics that serve as a training site for resident physicians throughout Indiana. The second step involved seeking pharmacist volunteers to distribute questionnaires to the resident physicians within their clinical site. Pharmacists were identified through convenience sampling based on a comprehensive list provided by the office of experiential education from colleges of pharmacy in Indiana, namely Purdue and Butler Universities. Though there is now a third pharmacy program within Indiana, at the time this research was conducted this program had not yet established their experiential training sites. Inclusion criteria for pharmacist participation required self-identification as a clinical practice site that provides longitudinal training for resident physicians, clinical site located within Indiana, and willingness to participate. Inclusion criteria for the resident physicians included currently participating in longitudinal ambulatory care clinical training at a site that includes an ambulatory care pharmacist as part of the healthcare team, clinical practice site located within Indiana, and completing an Internal Medicine, Family Medicine or Transitional Year medical residency. All participants were required to be greater than 18 years old and able to read English. Pharmacists and resident physicians not meeting the inclusion criteria were excluded from participation. This research was deemed exempt by the Indiana University Institutional Review Board (IRB).

Two unique questionnaires were developed, one to be completed by ambulatory care clinical pharmacists and one to be completed by resident physicians. The pharmacist questionnaire sought to describe the characteristics of their clinic settings and other aspects of their job. The resident physician questionnaire sought to assess perceptions and attitudes regarding working with ambulatory care pharmacists within clinics. Prior to item creation, researchers developed five main themes for which to assess resident physician perceptions and attitudes: quality of patient care provided by the pharmacist, level of autonomy provided by the pharmacist, role of the pharmacist as patient educator, role of the pharmacist as resident educator, and the pharmacists’ integration within the clinical care team. These themes were identified based on researchers’ past experiences with resident physicians and felt to encompass the unique roles an ambulatory care clinical pharmacist may be asked to undertake. Five point Likert scale items ranging from strongly agree to strongly disagree were developed by researchers for inclusion in the questionnaires, and had not been previously validated.

Pharmacist Survey

A statewide web-based questionnaire was developed for ambulatory care clinical pharmacists. An email was sent to
the identified pharmacists asking if their clinic served as a training site for resident physicians and included a link to an electronic questionnaire soliciting additional clinical practice information if they responded affirmatively. Only data indicating that they were part of an ambulatory care clinic that served as a training site for resident physicians were analyzed for the purposes of this study. Descriptive demographic information focused on the number of clinical pharmacists within the clinic who worked directly with resident physicians in a longitudinal manner, the number of full-time equivalent hours (FTE) the pharmacist(s) worked in the clinic, the number of half-days per week dedicated to providing clinical services, the types of services and activities that were offered within the longitudinal resident physician-training clinic and how long they had specifically provided services in their clinic. Finally, questions were asked about the types of involvement that the resident physicians had directly and indirectly with the clinical pharmacist and how often that interaction occurred.

Table 1. Pharmacist Questionnaire Items and Responses (n=15)

| Item                                                                 | Response n(%) |
|----------------------------------------------------------------------|---------------|
| How many pharmacists provide ambulatory care clinical pharmacy services on a regular basis at your individual clinic site? (mean SD) | 2.93; SD 1.91 |

Resident Physician Survey

Pharmacists identified as practicing in a longitudinal resident physician clinic were asked to forward an electronic questionnaire link to each resident physician within their clinic. Due to a low initial resident physician response rate, this data was discarded and a hard copy questionnaire was mailed to each participating pharmacist for the resident physicians within their clinics. All questionnaires were anonymous and, once complete, were placed in an envelope that was not located within the pharmacist’s office or direct workspace to maintain confidentiality and anonymity. The questionnaire focused on the perceptions of the resident physician and inquired about the types of services the ambulatory care pharmacist provided within their longitudinal clinic. Additional demographic information included the type of residency they were completing, current year of residency, and prior exposure to pharmacists and/or pharmacy students. Questionnaires were distributed April 1, 2015 through April 30, 2015. A reminder was electronically sent to participating pharmacists to encourage the resident physicians at their clinic to complete the questionnaire.

Data Analysis

Data were analyzed using SPSS 22 (IBM) software. A range of statistical tests were completed including basic

RESULTS
A total of 72 pharmacists received an invitation to participate. These pharmacists represented 51 unique clinical sites, although it is unknown how many serve as resident physician longitudinal training sites. Fifteen clinical pharmacists responded to the questionnaire (response rate=20.8%). As the clinic location was not a required response in order to maintain anonymity, it is unclear how many unique clinic sites these responses represented. Of the 15 pharmacists that completed the questionnaire, four agreed to facilitate distribution of the resident physician...
Resident physicians felt that the clinical pharmacist is a strong resident educator (73.3%) and most agreed that they would like the clinical pharmacist to be more formally involved in their clinical education (84.4%). They believed pharmacists provide education in a way that is different from physicians (86.7%) and that they use specific educational techniques to improve resident physician understanding of pharmacotherapy (84.4%).

Only four of the demographic items evaluated were associated with significant differences in responses. Resident physicians in the third year of their training and those that reported having a friend that was a pharmacist, were more likely to have a positive perception of the pharmacist’s role as a resident educator (p=0.048 and p=0.044, respectively). Those resident physicians who referred patients more frequently for clinical pharmacy appointments or reported prior exposure to pharmacists practicing in inpatient settings were more likely to respond favorably to the clinical pharmacist having autonomy with patient care (p=0.016 and p=0.033, respectively). Also, resident physicians responding with high levels of agreement to statements about the integration of pharmacists within the clinic team were more likely to report that one of their friends was a pharmacist (p=0.038).

Both pharmacists and resident physicians were asked the same questions to describe the types of pharmacy services offered and disease states managed within the clinics (Table 4). There were differences in pharmacist identified activities and resident physician identified pharmacist activities, with resident physicians over-identifying the types of services the clinical pharmacist provides, as compared to the pharmacist self-report.

**DISCUSSION**

Medical resident perceptions of pharmacists have not been well established in scientific literature. Based on the findings from this study, resident physicians perceive pharmacists that work within their longitudinal ambulatory clinic as providing effective patient education and a high quality of care to the patients that are referred for clinical pharmacy services. The majority of respondents indicated that they strongly agreed or agreed that the pharmacists in their clinics had the appropriate clinical training to provide the level of care for the services offered and were confident in the abilities of the pharmacist with whom they have a relationship, similar to reports of non-resident physicians.14,17 Additionally, the majority of resident physicians in this study either strongly agreed or agreed that care provided by the pharmacist is different than the services offered by the physicians. Pharmacists are able to conduct focused visits for one or two disease states that incorporate not only pharmacotherapy, but also non-pharmacological elements pertaining to the patient’s lifestyle such as dietary and physical activity. This varies from an appointment conducted by a physician that may need to focus on a wide array of disease states not allowing for adequate time to fully incorporate pharmacologic and non-pharmacologic treatment options.
Achieve improved quality areas for which he/she currently is qualified for these perceptions, a number of possibilities may exist. These perceptions could be a direct reflection of resident physician questionnaire perception items and responses. n (%)

| Referring patients to a clinical pharmacist for medication management hurts my relationship with the patient. (Quality of care) | 0 (0) | 2 (4.4) | 2 (4.4) | 27 (60) | 14 (31.3) |
| I am confident in the clinical pharmacist’s ability to manage, monitor, and counsel patients on their medications and disease state(s) based on current guidelines. (Quality of care) | 26 (57.8) | 18 (40) | 1 (2.2) | 0 (0) | 0 (0) |
| I am comfortable with the care my patients will receive when referred to the clinical pharmacist at my longitudinal clinic. (Quality of care) | 24 (53.3) | 20 (44.4) | 1 (2.2) | 0 (0) | 0 (0) |

Perhaps the most surprising finding from this survey is that despite the resident physicians viewing the pharmacist as being qualified to provide education and clinical services, while also being confident in the clinical pharmacists’ ability to manage, monitor, and counsel patients on their medications, a small subset of resident physicians felt that referring patients to the clinical pharmacist for medication management could hurt their relationships with patients. While this research was not designed to discover reasons for these perceptions, a number of possibilities may exist. These perceptions could be a direct reflection of resident physicians indicating that they did not get to spend enough time with the clinical pharmacist to become completely comfortable with the concept of patient referral and independent pharmacist management, while also lacking a full awareness of the disease states managed and broad scope of services provided by the pharmacist. This could be remedied through formal shadowing or joint appointments between the resident physician and clinical pharmacist at the start of, and periodically throughout, the longitudinal clinic experience, or simple distribution of a handout during the resident physician’s first year in clinic that clearly explains and identifies the various roles of the clinical pharmacist.

There is a need for increased awareness of the role of the clinical pharmacist as shown by the discrepancy seen
The frequency of patient follow-up visits, especially for chronic disease states, varies among the settings in which these patients are treated. One such setting is the ambulatory care pharmacy, where resident physicians and pharmacists may not have a clear understanding of the services each provides. However, the majority of both resident physicians and pharmacists responded that the pharmacist provides care for disease state education (86.7% of resident physicians vs. 93.3% of the pharmacists). In contrast, only 62.2% of the resident physicians felt that the pharmacist is involved in weight loss, whereas 86.7% of the pharmacists noted involvement (Table 4). Of note, only 57.8% of resident physicians responded that the pharmacist provides disease state education versus 93.3% of the pharmacists. A lack of awareness of the pharmacists’ services by resident physicians may reduce referrals and limit the pharmacist’s ability to provide services.

One of the largest benefits to utilizing ambulatory care pharmacists for patient management is that by allowing the pharmacist to focus on the management of specific disease states through frequent follow-up visits, resident physicians may have more time to attend to medical issues that may require their attention. The frequency of patient follow-up visits is a major concern for both resident physicians and pharmacists. A resident physician appointment may not be for a few months but rather every few weeks whereas the first available resident physician appointment may not be for a few months.

Additionally, the concern regarding impact on patient relationship may support the idea that the resident physicians would like the pharmacist to be more directly involved in their clinical education during their ambulatory care learning experience by leading topic discussions or providing relevant presentations. In certain settings, such as what is seen within the Veteran’s Affairs (VA) environment, the view of the clinical pharmacist’s role in the approval or denial of non-formulary medication requests may contribute to this view of “harm” to the patient relationship. Almost half (48.9%) of the resident physicians identified non-formulary medication requests as a service in which their pharmacist was involved. When a non-formulary medication is denied or an alternate medication is suggested in place of the non-formulary medication being requested, this could be viewed by the resident physician as hindering the relationship the physician has with the patient.

Slightly more than half of the resident physicians in this study strongly agreed or agreed that the pharmacist is qualified to provide additional services than those currently being offered at their clinics. Resident physicians’ limited knowledge of the PharmD curriculum and limited collaboration with pharmacy students on projects during medical school may be contributing factors as to why a notable number of resident physicians were neutral and a few disagreed with pharmacists being able to provide additional services. Medical and pharmacy schools throughout the United States are focusing on incorporating interprofessional education (IPE) into the curriculum. It is worth noting that residency training, whether pharmacy or medical, is a perfect venue to implement IPE. While this

### Table 4. Comparison of Pharmacist Services, n (%)

| Disease States Managed | Resident Response | Pharmacist Response |
|------------------------|------------------|---------------------|

Meredith AH, Ramsey D, Schmelz A, Berglund R. Resident physicians’ perceptions of ambulatory care pharmacy. Pharmacy Practice 2019 Jul-Sep;17(3):1509. https://doi.org/10.18549/PharmPract.2019.3.1509
study did not specifically focus on IPE, it is worthwhile to note that 82.2% of resident physicians had not collaborated with pharmacy students on any projects during their medical school training and 13.3% had no prior exposure to pharmacists prior to starting their longitudinal clinic experience. While this does not represent all medical schools, it showcases the struggle that some medical programs may have with incorporating IPE into professional school training, and how a lack of IPE early in training can influence perceptions of working with varied healthcare disciplines. Additionally, the responses which differed based on demographic factors all follow what is known about establishing effective pharmacist-physician collaboration; colocation, past experiences, and ability to communicate effectively are important factors in establishing collaboration.14,18 The responses of resident physicians that have a friend that is a pharmacist support these concepts as a deeper relationship has been formed. Concerted efforts should be made to provide all health care professionals in training with opportunities to work closely with trainees from other disciplines, whether through the completion of multidisciplinary group projects while in school or some other manner while receiving clinical training.

One limitation that should be noted is that of survey bias. While all efforts were made to minimize any bias from the survey instrument, the use of a hard copy survey instrument may have impacted resident physicians’ responses if there was concern that responses would be viewed by the clinical pharmacist with whom they directly work. Selection bias may also have occurred. Pharmacists were identified based on established preceptor relationships with pharmacy programs, which would exclude any non-preceptor pharmacists from participating. Additionally, pharmacists were asked to distribute the questionnaires to all resident physicians at their practice site, but may have only distributed questionnaires to the resident physicians at their site with whom they had good relationships or expected positive feedback from. An additional limitation is the small sample size and moderate response rate, however physician response rates to surveys are typically low and some studies have shown that response rates in this population are declining over time.19–23 Our resident physician response rate of 42% is similar to other studies.15–22

This research highlights the perceptions of resident physicians within Indiana and may not be representative of views throughout the country. Investigators successfully attempted to increase the response rate following the initial study pilot period by changing the questionnaire administration method. However, based on the research methods it is uncertain how many medical residency programs include clinical pharmacists as part of the ambulatory care healthcare team or how many unique training sites were represented among the 15 pharmacist responses. Given the small number of distributing pharmacists, the results may be more of a reflection of these specific pharmacists rather than overall perceptions of ambulatory care pharmacy services throughout Indiana, although aligned with the perceptions of non-resident physicians.14,27 Researchers attempted to be as comprehensive as possible in identifying potential sites for participation, however there is not a master list of pharmacists practicing in the ambulatory care setting, nor is there a comprehensive list of longitudinal ambulatory care training sites for resident physicians in Indiana.

CONCLUSIONS
This novel research highlights the perceptions of ambulatory care clinical pharmacists within resident physician longitudinal ambulatory care clinics. Resident physicians with a longer duration of exposure and personal friendship with a pharmacist are more likely to express positive perceptions. Areas for further enhancements in this interprofessional relationship have been identified related to perceptions about pharmacist autonomy and patient relationships.

PRESENTATIONS
A poster presentation about this project was presented in December 2014 at the American Society of Health-System Pharmacists (ASHP) Midyear Clinical Meeting in Anaheim, CA; a lecture presentation about this project was delivered at the Family Medicine Midwest Conference on October 8, 2016 in Indianapolis, IN.

CONFLICT OF INTEREST
No authors report any conflicts of interest.

FUNDING
This research did not receive any specific grant from funding agencies in the public, commercial, or not-for-profit sectors.
