Global Division of Cohomology Classes via Injectivity

Lawrence Ein & Mihnea Popa

Dedicated to Mel Hochster on his 65th birthday

1. Introduction

The aim of this note is to remark that the injectivity theorems of Kollár and Esnault–Viehweg can be used to give a quick algebraic proof of a strengthening (by dropping the positivity hypothesis) of the Skoda-type division theorem for global sections of adjoint line bundles vanishing along suitable multiplier ideal sheaves (proved in [EL]) and to extend this result to higher cohomology classes as well (cf. Theorem 4.1). For global sections, this is a slightly more general statement of the algebraic version of an analytic result of Siu [S] based on the original Skoda theorem. In Section 4 we list a few consequences of this type of result, such as the surjectivity of various multiplication or cup product maps and the corresponding version of the geometric effective Nullstellensatz.

Along the way, in Section 3 we write down an injectivity statement for multiplier ideal sheaves (Theorem 3.1) and its implicit torsion-freeness and vanishing consequences (Theorem 3.2). These statements are not required in this generality for the main result here (see the following paragraph), but having them available will hopefully be of use. Modulo some standard tricks, the results in Section 3 reduce quickly to theorems of Kollár [K1] and Esnault and Viehweg [EsV], and we do not claim originality in any of the proofs.

All of the results are proved in the general setting of twists by nef and abundant (or good) line bundles, which replace twists by nef and big line bundles required for the use of vanishing theorems. In particular, what is used in the proof of the main Skoda-type statement is a Kollár vanishing theorem for the higher direct images of adjoint line bundles of the form $K_X + L$, where $L$ is the round-up of a nef and abundant $\mathbb{Q}$-divisor. For such vanishing, the only contribution we bring here is a natural statement that seems to be slightly more general that what we found in the literature (cf. Corollary 3.3(4)). The proof is otherwise standard after establishing a simple lemma on restrictions of nef and abundant divisors in Section 2.

Mel Hochster used tight closure techniques to give a beautiful treatment to local statements of Briançon–Skoda type in positive characteristic. We are very happy to be able to contribute work in a similar circle of ideas to a volume in his honor.

2. Preliminaries

Injectivity. We always work with varieties defined over an algebraically closed field of characteristic 0. We first recall that the approach to vanishing theorems described by Esnault and Viehweg in [EsV] produces the following injectivity statement. (Note that [EsV, 5.1] contains a slightly more general statement that allows for adding an extra effective divisor under some transversality conditions; we will not make use of this here.)

**Theorem 2.1 [EsV, 5.1].** Let $X$ be a smooth projective variety, and let $L$ be a line bundle on $X$. Assume that there exists a reduced simple normal crossings divisor $\sum_i \Delta_i$ such that we can write $L \sim \sum_i \delta_i \Delta_i$, with $0 < \delta_i < 1$ for all $i$. If $B$ is any effective divisor supported on $\sum_i \Delta_i$, then the natural maps

$$H^i(X, \mathcal{O}_X(K_X + L)) \rightarrow H^i(X, \mathcal{O}_X(K_X + L + B))$$

are injective for all $i$.

Nef and Abundant Divisors. Recall next that a nef $\mathbb{Q}$-divisor $D$ is called abundant (or good) if $\kappa(D) = \nu(D)$—that is, if its Iitaka dimension is equal to its numerical dimension (the largest integer $k$ such that $D^k \cdot Y \neq 0$ for some $Y \subseteq X$ of dimension $k$). Note that a semiample divisor is abundant, and so is a divisor that is big and nef. We recall the following basic description due to Kawamata.

**Lemma 2.2 [Ka, Prop. 2.1; EsV, Lemma 5.11].** For a $\mathbb{Q}$-divisor $B$ on a normal projective variety $X$, the following statements are equivalent:

(i) $B$ is nef and abundant.

(ii) There exists a birational morphism $\phi: W \rightarrow X$, with $W$ smooth and projective, and a fixed effective divisor $F$ on $W$ such that, for any $m$ sufficiently large and divisible, $\phi^*(mB) = A + F$ with $A$ semiample.

The following simple restriction statement will be used to note that Kollár vanishing holds for higher direct images of $K_X + B$, where $B$ is nef and abundant without restrictions. This fact is needed here and is slightly stronger than results stated in the literature (cf. Theorem 3.2(iii) and Corollary 3.3(iv)).

**Lemma 2.3.** Let $X$ be a normal projective variety and $B$ a nef and abundant $\mathbb{Q}$-divisor on $X$.

(i) If $L$ is a globally generated line bundle on $X$ and if $D \in |L|$ is a general divisor, then $B|_D$ is also nef and abundant.

(ii) If $C$ is another nef and abundant $\mathbb{Q}$-divisor on $X$, then $B + C$ is also nef and abundant.

(iii) If $f: Y \rightarrow X$ is a surjective morphism from another normal projective variety, then $f^*B$ is nef and abundant.

**Proof.** For (i), we need only show that $B|_D$ is abundant. This follows most easily from the preceding description. Consider a birational morphism $\phi: W \rightarrow X$...
as in Lemma 2.2. If \( \tilde{D} \) is the proper transform of \( D \), we can choose \( D \) such that \( \phi|_D \) is an isomorphism at the generic point of \( D \), \( \tilde{D} \) is smooth, and no component of \( \tilde{D} \) is contained in \( \text{Supp}(F) \). In this case we have an induced decomposition \( (\phi|_{\tilde{D}})^*(mB|_D) = A|_\tilde{D} + F|_{\tilde{D}} \) for all \( m \) sufficiently large and divisible. By Lemma 2.2, this shows that \( B|_D \) is abundant. Parts (ii) and (iii) follow immediately from the same characterization in Lemma 2.2.

\[ \text{Remark 2.4.} \quad \text{Although we will not use this, it is worth pointing out the following more precise statement, which can be obtained by a closer analysis of the characterization in [Ka, Prop. 2.1]. In the setting of Lemma 2.3, assume that} \quad \kappa(B) = k. \]

\[ \text{We always have} \quad B^k \cdot L^n - k \geq 0 \quad \text{and, when the restriction} \quad B|_D \text{ is nef and abundant:} \]
\[ \kappa(B|_D) = k \quad \text{iff} \quad B^k \cdot L^n - k > 0 \quad \text{and} \quad \kappa(B|_D) = k - 1 \quad \text{iff} \quad B^k \cdot L^n - k = 0. \]

\section{3. Injectivity for Q-Divisors and Multiplier Ideals}

In this section we write down the proof of an injectivity statement for multiplier ideals. This is a consequence of Theorem 2.1 and follows quickly from it via standard tricks. For the appropriate level of generality, we use multiplier ideals associated to ideal sheaves. The equivalent divisorial condition (on the log-resolution) is stated at the beginning of the proof. Throughout, by “\( \mathbb{Q} \)-effective” we mean “\( \mathbb{Q} \)-linearly equivalent to an effective divisor”.

\[ \text{Theorem 3.1.} \quad \text{Let} \quad X \text{ be a smooth projective variety,} \quad a \subseteq O_X \text{ an ideal sheaf, and} \quad L \text{ a line bundle on} \quad X. \quad \text{Consider also} \quad A \text{ a line bundle with} \quad A \otimes a \text{ globally generated,} \quad B \text{ an effective divisor, and} \quad \lambda \in \mathbb{Q} \text{ such that} \]
\[ \text{•} \quad L - \lambda A \text{ is nef and abundant and} \]
\[ \text{•} \quad L - \lambda A - \varepsilon B \text{ is} \quad \mathbb{Q} \text{-effective for some} \quad 0 < \varepsilon < 1. \]

\[ \text{Then the natural maps} \quad H^i(X, \mathcal{O}_X(K_X + L) \otimes J(X, a^\lambda)) \rightarrow H^i(X, \mathcal{O}_X(K_X + L + B) \otimes J(X, a^\lambda)) \]
\[ \text{are injective for all} \quad i. \]

\[ \text{Proof.} \quad \text{Let} \quad f : Y \rightarrow X \text{ be a log-resolution of the ideal} \quad a, \text{ with} \quad a \cdot O_Y = O_Y(-E). \quad \text{The two hypotheses in the theorem imply that:} \]
\[ \text{•} \quad f^*L - \lambda E = f^*(L - \lambda A) + \lambda(f^*A - E) \text{ is nef and abundant (by (ii) and (iii) of Lemma 2.3);} \]
\[ \text{•} \quad f^*L - \lambda E - \varepsilon f^*B \text{ is} \quad \mathbb{Q} \text{-effective for some} \quad 0 < \varepsilon < 1. \]

\[ \text{We recall that, by definition,} \quad J(X, a^\lambda) = f_*O_Y(K_{Y/X} - [\lambda E]). \quad \text{The projection formula and the local vanishing theorem (cf. [L2, 9.4.4]) imply that we have isomorphisms} \]
\[ H^i(Y, O_Y(K_Y + f^*L - [\lambda E])) \cong H^i(X, O_X(K_X + L) \otimes J(X, a^\lambda)) \]
\[ \text{and their analogues with} \quad B \text{ added. Hence it is enough to show injectivity on} \quad Y \quad \text{— namely, for the maps} \]
\[ H^i(Y, O_Y(K_Y + f^*L - [\lambda E])) \rightarrow H^i(Y, O_Y(K_Y + f^*L - [\lambda E] + f^*B)). \]
By assumption there exists an $a \in \mathbb{N}$ such that $a(f^*L - \lambda E - \varepsilon f^*B) \sim B'$, where $B'$ is an integral effective divisor. On the other hand, $f^*L - \lambda E$ is nef and abundant, and we may assume that the log-resolution $f$ factors through the birational morphism $\phi$ of Lemma 2.2. Hence we can write $f^*L - \lambda E = A' + F$, where $A'$ is a semiample $\mathbb{Q}$-divisor and $F$ is an effective $\mathbb{Q}$-divisor with fixed support but arbitrarily small coefficients. In particular, for $N \gg 0$ we can write $(N-a)A' \sim P$, where $P$ is a reduced, irreducible divisor. We can then write down a decomposition

$$f^*L - \lambda E = \frac{1}{N} (a(f^*L - \lambda E) + (N-a)A' + (N-a)F) \sim \alpha f^*B + \beta B' + \gamma P + \frac{N-a}{N} F,$$

with $\alpha, \beta, \gamma$ arbitrarily small.

We claim that, by passing to a log-resolution of the pair $(X, E + f^*B + B' + P + F)$, we can assume in addition that everything is in simple normal crossings. Let’s assume this in order to conclude. Denote $\Delta' := \lambda E - [\lambda E]$. Using (1), we can write

$$f^*L - [\lambda E] \sim \alpha f^*B + \beta B' + \gamma P + \frac{N-a}{N} F.$$

Note that $\Delta'$ may have common components with some of the other divisors appearing in the expression on the right-hand side. However, since their coefficients can be made arbitrarily small, we can assume that every irreducible divisor in the sum appears with coefficient less than 1. Consequently we can apply Theorem 2.1, with the role of $L$ played by $f^*L - [\lambda E]$ and that of $B$ by $f^*B$.

It remains to prove our claim. Toward this end, note that our choices yield the following. If we denote

$$T := \Delta' + \alpha f^*B + \beta B' + \gamma P + \frac{N-a}{N} F,$$

then $(Y, T)$ is a klt pair, and we have seen that $f^*L - [\lambda E] \sim Q T$. Let $g : Z \to Y$ be a log-resolution of $(Y, T)$. Then

$$\mathcal{J}(Y, T) = g_* \mathcal{O}_Z(K_Z/Y - [g^*T]) \cong \mathcal{O}_Y.$$

Applying again the local vanishing theorem cited previously, we see that it is enough to prove injectivity on $Z$ for the map

$$H^1(Z, \mathcal{O}_Z(K_Z + g^*(f^*L - [\lambda E]) - [g^*T])) \to H^1(Z, \mathcal{O}_Z(K_Z + g^*(f^*L - [\lambda E]) - [g^*T] + g^*f^*B)).$$

But $g^*(f^*L - [\lambda E]) - [g^*T] \sim Q [g^*T]$, which reduces us to the simple normal crossings situation.

Theorem 3.1 implies standard torsion-freeness and vanishing consequences for images of twisted multiplier ideal sheaves, in analogy with Kollár’s [K1, Thm. 2.1].
Theorem 3.2. Let $X$ be a smooth projective variety, and let $f : X \to Y$ be a surjective morphism to a projective variety $Y$. Let $a \subset \mathcal{O}_X$ be an ideal sheaf and $A$ a line bundle on $X$ such that $A \otimes a$ is globally generated. Let $\lambda \in \mathbb{Q}$ and let $L$ be a line bundle on $X$ such that $L - \lambda A$ is nef and abundant. Then:

(i) $R^i f_*(\mathcal{O}_X(K_X + L) \otimes \mathcal{J}(a^\lambda))$ are torsion-free for all $i$;
(ii) $R^i f_*(\mathcal{O}_X(K_X + L) \otimes \mathcal{J}(a^\lambda)) = 0$ for $i > \dim(X) - \dim(Y)$;
(iii) $H^j(Y, R^i f_*(\mathcal{O}_X(K_X + L) \otimes \mathcal{J}(a^\lambda)) \otimes M) = 0$ for all $i$ and all $j > 0$, where $M$ is any big and nef line bundle on $Y$.

Proof. For the convenience of the reader we sketch briefly how this can be deduced from injectivity—in this case, Theorem 3.1. All the main ideas are, of course, contained in [K1] and [EsV].

The assertion in (ii) is an immediate consequence of (i) and base change. For (i), consider $N$ a sufficiently positive line bundle on $Y$. If $R^i f_*(\mathcal{O}_X(K_X + L) \otimes \mathcal{J}(a^\lambda))$ had torsion, we would be able to choose $D \in |N|$ such that the natural map on global sections

$H^0(Y, R^i f_*(\mathcal{O}_X(K_X + L) \otimes \mathcal{J}(a^\lambda)) \otimes N)$

$\to H^0(Y, R^i f_*(\mathcal{O}_X(K_X + L) \otimes \mathcal{J}(a^\lambda)) \otimes N(D))$

is not injective. On the other hand, for $N$ positive enough, by the degeneration of the corresponding Leray spectral sequences we see that the foregoing map is the same as the natural homomorphism

$H^i(X, \mathcal{O}_X(K_X + L + f^*N) \otimes \mathcal{J}(a^\lambda))$

$\to H^i(X, \mathcal{O}_X(K_X + L + f^*N + f^*D) \otimes \mathcal{J}(a^\lambda))$.

Note that $f^*N$ is semiample on $X$ and so, by Lemma 2.3(ii), the $\mathbb{Q}$-divisor $L + f^*N - \lambda A$ is still nef and abundant. We can then apply Theorem 3.1 to derive a contradiction, since the other condition in the theorem is obviously satisfied.

For (iii) one uses induction on the dimension of $X$. We sketch the proof only for the case of $M$ ample, which implies the big and nef case via a standard use of Kodaira’s lemma. For some integer $p \gg 0$, consider $Y_0 \in |pM|$ a general divisor such that $X_0 = f^{-1}(Y_0)$ is a smooth divisor in $X$. Fix an $i$, and for simplicity denote $\mathcal{F} := \mathcal{O}_X(K_X + L) \otimes \mathcal{J}(a^\lambda)$. Then we have the exact sequence

$0 \to \mathcal{F} \to \mathcal{F}(X_0) \to \mathcal{F}(X_0)|_{X_0} \to 0$.

Pushing this forward to $Y$, for each $i$ we obtain exact sequences

$0 \to R^i f_* \mathcal{F} \to R^i f_*(\mathcal{F}(X_0)) \to R^i f_*(\mathcal{F}(X_0)|_{X_0}) \to 0$.

The reason these sequences are exact at the extremities is that, by (i), the sheaves $R^i f_* \mathcal{F}$ are torsion-free while the $R^i f_*(\mathcal{F}(X_0)|_{X_0})$ are generically zero. Twisting this with $M$ and recalling that $p \gg 0$, we immediately obtain
\[ H^{i+j}(Y, R^if_*\mathcal{F} \otimes M) \cong H^i(Y_0, R^if_*(\mathcal{F}(X_0)|_{X_0}) \otimes M_{Y_0}) \quad \text{for all } j \geq 1. \]

Since \( Y_0 \) was chosen to be general, the restriction \((L - \lambda A)|_{X_0}\) is still nef and abundant by Lemma 2.3(i), while by [L2, 9.5.35] we have \( \mathcal{F}(a^i \cdot \mathcal{O}_{X_0}) \cong \mathcal{F}(a^i \cdot \mathcal{O}_{X_0}) \). Thus, by induction on the dimension, we can apply (iii) to the right-hand side above and deduce the conclusion on \( Y \) for \( j \geq 2 \).

We are left with the case \( j = 1 \). Consider again \( p \gg 0 \), and choose a divisor \( D \in |pM| \) such that \( H^1(Y, R^if_*\mathcal{F} \otimes M(D)) = 0 \). We then have a Leray spectral sequence,

\[ E_2^{i,j} : H^i(Y, R^if_*\mathcal{F} \otimes M) \Rightarrow H^{i+j}(X, \mathcal{F} \otimes f^*M). \]

By the previous paragraph, the \( E_2^{i,j} \) are zero for \( j \geq 2 \); then, chasing the spectral sequence easily gives that we have an injective map

\[ H^1(Y, R^if_*\mathcal{F} \otimes M) \hookrightarrow H^1(X, \mathcal{F} \otimes f^*M). \]

Analogously, there is a similar injective map after twisting with \( D \). But Theorem 3.1 shows that the map

\[ H^{i+1}(X, \mathcal{F} \otimes f^*M) \rightarrow H^{i+1}(X, \mathcal{F} \otimes f^*M(D)) \]

is injective, so all of this implies (finally) that the map

\[ H^1(Y, R^if_*\mathcal{F} \otimes M) \rightarrow H^1(Y, R^if_*\mathcal{F} \otimes M(D)) \]

is also injective. However, this last group is zero. \( \square \)

A special case of the two theorems in this section is the following result for \( \mathbb{Q} \)-divisors. The first part is already explicitly stated by Esnault and Viehweg [EsV] and is an extension of Kollár’s injectivity theorem [K1, Thm. 2.2]; parts (ii) and (iii), of course, follow directly from it. Part (iv) is stated a little less generally in [EsV, 6.17(b)]. We will need the following formulation.

**Corollary 3.3.** Let \( L \) a line bundle on a smooth projective \( X \), and let \( \Delta = \sum \delta_i \Delta_i \) be a simple normal crossings divisor with \( 0 < \delta_i < 1 \) for all \( i \). Assume that \((L - \Delta)\) is nef and abundant and that \( B \) is an effective Cartier divisor such that \( \lambda = \lambda - \varepsilon B \) is \( \mathbb{Q} \)-effective for some \( 0 < \varepsilon < 1 \). Consider also a morphism \( f : X \rightarrow Y \) with \( Y \) projective. Then the following statements hold.

(i) The natural maps

\[ H^i(X, \mathcal{O}_X(K_X + L)) \rightarrow H^i(X, \mathcal{O}_X(K_X + L + B)) \]

are injective for all \( i \) [EsV, 5.12(b)].

(ii) \( R^if_*\mathcal{O}_X(K_X + L) \) are torsion-free for all \( i \).

(iii) \( R^if_*\mathcal{O}_X(K_X + L) = 0 \) for \( i > \dim(X) - \dim(Y) \).

(iv) \( H^j(Y, R^if_*\mathcal{O}_X(K_X + L) \otimes M) = 0 \) for all \( i \) and all \( j > 0 \), where \( M \) is any big and nef line bundle on \( Y \).
4. Skoda-type Global Division Theorem

For the objects involved in the statement of Theorem 4.1, recall the following. If \( f : Y \to X \) is a common log-resolution for ideal sheaves \( a \) and \( b \), where \( a \cdot \mathcal{O}_Y = \mathcal{O}_Y(-E) \) and \( b \cdot \mathcal{O}_Y = \mathcal{O}_Y(-F) \), and if \( \mu, \lambda \in \mathbb{Q}_+ \), then the “mixed” multiplier ideal is defined as \( \mathcal{J}(a^\mu \cdot b^\lambda) = f_* \mathcal{O}_Y(K_{Y/X} - [\mu E + \lambda F]) \) (cf. [L2, 9.2.8]). For a line bundle \( B \) on \( X \), we say that \( B \otimes b^i \) is nef and abundant if the \( \mathbb{Q} \)-divisor \( f^*B - \lambda F \) is nef and abundant on \( Y \). These definitions are independent of the log-resolution we choose.

**Theorem 4.1.** Let \( X \) be a smooth projective variety of dimension \( n \), and let \( a, b \subseteq \mathcal{O}_X \) be ideal sheaves. Consider line bundles \( L \) and \( B \) on \( X \) such that \( L \otimes a \) is globally generated and \( B \otimes b^k \) is nef and abundant for some \( \lambda \in \mathbb{Q}_+ \). Then, for every integer \( m \geq n + 2 \), the sections in

\[
H^0(X, \mathcal{O}_X(K_X + mL + B) \otimes \mathcal{J}(a^m \cdot b^k))
\]
can be written as linear combinations (with coefficients in \( H^0(L) \)) of sections in

\[
H^0(X, \mathcal{O}_X(K_X + (m-1)L + B) \otimes \mathcal{J}(a^{m-1} \cdot b^k)).
\]

More generally, for every \( i \geq 0 \), the cohomology classes in

\[
H^i(X, \mathcal{O}_X(K_X + mL + B) \otimes \mathcal{J}(a^m \cdot b^k))
\]
can be written as linear combinations (with coefficients in \( H^0(L) \), via cup product) of classes in \( H^i(X, \mathcal{O}_X(K_X + (m-1)L + B) \otimes \mathcal{J}(a^{m-1} \cdot b^k)) \).

**Proof.** Let \( f : Y \to X \) be a common log-resolution for \( a \) and \( b \), where \( a \cdot \mathcal{O}_Y = \mathcal{O}_Y(-E) \) and \( b \cdot \mathcal{O}_Y = \mathcal{O}_Y(-F) \). Let’s assume that \( L \otimes a \) is generated by \( s \geq n + 1 \) sections spanning a linear subspace \( V \subseteq H^0(L) \). In fact, it will be clear from the proof that if \( L \otimes a \) happens to be spanned by \( p \leq n \) sections then the result can be improved, with an identical argument, by replacing \( n + 1 \) with \( p \).

The line bundle \( A := f^*L - E \) will be generated by the corresponding space of sections in \( H^0(A) \), which we denote also by \( V \). Denote by \( g : Y \to Z \subseteq \mathbb{P}^{s-1} \) the map it determines, so that \( A \cong g^*\mathcal{O}_Z(1) \). The goal is to prove the surjectivity of the multiplication map

\[
V \otimes H^0(X, \mathcal{O}_X(K_X + (m-1)L + B) \otimes \mathcal{J}(a^{m-1} \cdot b^k)) \to H^0(X, \mathcal{O}_X(K_X + mL + B) \otimes \mathcal{J}(a^m \cdot b^k)).
\]

Note, however, that by definition we have

\[
\mathcal{J}(a^k \cdot b^k) = f_* \mathcal{O}_Y(K_{Y/X} - kE - [\lambda F]) \quad \text{for all } k,
\]

so this is equivalent to the surjectivity of the multiplication map

\[
V \otimes H^0(Y, \mathcal{O}_Y(K_Y + (m-1)f^*L + f^*B - (m-1)E - [\lambda F])) \to H^0(Y, \mathcal{O}_Y(K_Y + mf^*L + f^*B - mE - [\lambda F])).
\]
Recall the notation $A = f^*L - E$ and denote $N = f^*B - [\lambda F]$, which by assumption can be written as a nef and abundant $\mathbb{Q}$-divisor plus a simple normal crossings boundary divisor. Rewriting the preceding map, we are then interested in the surjectivity of the multiplication map

$$V \otimes H^0(Y, \mathcal{O}_Y(K_Y + (m - 1)A + N)) \longrightarrow H^0(Y, \mathcal{O}_Y(K_Y + mA + N)).$$ (2)

We compare this with the picture obtained by pushing forward to $Z$ via $g$. Note that $V$ can be considered as a space of sections generating $\mathcal{O}_Z(1)$. It is well known that this gives rise to an exact Koszul complex on $Z$ (cf. e.g. [L1, beginning of Apx. B.2]):

$$0 \longrightarrow \Lambda^s V \otimes \mathcal{O}_Z(-s) \longrightarrow \cdots \longrightarrow \Lambda^2 V \otimes \mathcal{O}_Z(-2) \longrightarrow V \otimes \mathcal{O}_Z(-1) \longrightarrow \mathcal{O}_Z \longrightarrow 0.$$

We twist this with the sheaf $g_*\mathcal{O}_Y(K_Y + N) \otimes \mathcal{O}_Z(m)$, which preserves the exactness of the sequence

$$0 \longrightarrow \Lambda^s V \otimes \mathcal{O}_Z(m - s) \otimes g_*\mathcal{O}_Y(K_Y + N) \longrightarrow \cdots$$

$$\longrightarrow V \otimes \mathcal{O}_Z(m - 1) \otimes g_*\mathcal{O}_Y(K_Y + N) \longrightarrow \mathcal{O}_Z(m) \otimes g_*\mathcal{O}_Y(K_Y + N) \longrightarrow 0.$$

(Note that the Koszul complex is locally split and its syzygies are locally free, so twisting by any coherent sheaf preserves exactness.) Since $A \cong g^*\mathcal{O}_Z(1)$, the surjectivity of the map in (2) is equivalent to the surjectivity of the multiplication map

$$V \otimes H^0(Z, \mathcal{O}_Z(m - 1) \otimes g_*\mathcal{O}_Y(K_Y + N))$$

$$\longrightarrow H^0(Z, \mathcal{O}_Z(m) \otimes g_*\mathcal{O}_Y(K_Y + N))$$

induced by the taking global sections in the foregoing Koszul complex. But since $m \geq n + 2$, the line bundle case of Corollary 3.3(iv) implies that

$$H^j(Z, \mathcal{O}_Z(m - i) \otimes g_*\mathcal{O}_Y(K_Y + N)) = 0 \quad \text{for all} \quad j > 0 \quad \text{and} \quad i \leq n + 1.$$

By chasing through the induced short exact sequences, this easily implies that the entire Koszul complex stays exact after passing to global sections. (Note that beyond $i = n + 1$ we are, as before, interested only in cohomology groups for $j > n$, which are automatically zero.) This proves the statement for global sections.

The proof of the general statement for cohomology classes is similar. Note first that, again by Corollary 3.3(iv), for higher direct images we have that, for every $i$ and every $k > 0$, the Leray spectral sequence degenerates to an isomorphism

$$H^i(Y, \mathcal{O}_Y(K_Y + kA + N)) \cong H^0(Z, R^i g_*\mathcal{O}_Y(K_Y + N) \otimes \mathcal{O}_Z(k)).$$

But, exactly as before, the same vanishing applied yet again for $R^i g_*\mathcal{O}_Y(K_Y + N)$ implies that, after twisting the Koszul complex with $R^i g_*\mathcal{O}_Y(K_Y + N)$ and passing to global sections, we obtain the surjection

$$V \otimes H^0(Z, \mathcal{O}_Z(m - 1) \otimes R^i g_*\mathcal{O}_Y(K_Y + N))$$

$$\longrightarrow H^0(Z, \mathcal{O}_Z(m) \otimes R^i g_*\mathcal{O}_Y(K_Y + N)).$$

This implies the surjectivity of the cup product.
Global Division of Cohomology Classes via Injectivity

\[ V \otimes H^i(Y, O_Y(K_Y + (m - 1)A + N)) \rightarrow H^i(Y, O_Y(K_Y + mA + N)). \]

On the other hand, by the local vanishing theorem we have

\[ R^j f_* O_Y(K_Y - kE - [\lambda F]) = 0 \quad \text{for all } j > 0 \text{ and } k > 0 \]

and so, for all \( i \),

\[ H^i(X, O_X(K_X + mL + B) \otimes J(a^m \cdot b^i)) \cong H^i(Y, O_Y(K_Y + kA + N)). \]

The result follows.

Taking \( b = O_X \) in the theorem yields the following corollary.

**Corollary 4.2.** In the notation of Theorem 4.1, if \( B \) is a nef and abundant line bundle (e.g., \( B = O_X \)) then, for every \( m \geq n + 2 \) and every \( i \), the cohomology classes in

\[ H^i(X, O_X(K_X + mL + B) \otimes J(a^m)) \]

can be written as linear combinations of classes in

\[ H^i(X, O_X(K_X + mL + B) \otimes J(a^{m-1})). \]

In the case of global sections (i.e., \( i = 0 \)), this result is an improvement of the global division theorem of [EL] (cf. [L2, Thm. 9.6.31]): one does not require twisting with an ample (or big and nef) line bundle. (Note, however, that in order to do this we must start with \( m = n + 2 \), not with \( m = n + 1 \).) Also, for \( i = 0 \), Corollary 4.2 is a slightly more general version of the algebraic version of the Skoda-type theorem proved in the analytic context by Siu [S, Thm. 1.8.3]. Observe that the method used here does not distinguish between global sections and higher cohomology classes. The case of trivial multiplier ideals already yields a slightly surprising statement even in the case \( B = O_X \), as follows.

**Corollary 4.3.** Let \( L \) be a globally generated line bundle and \( B \) a nef and abundant line bundle on a smooth projective variety \( X \) of dimension \( n \). Then, for all \( m \geq n + 2 \) and all \( i \geq 0 \), the cup product maps

\[ H^0(X, L) \otimes H^i(X, O_X(K_X + (m - 1)L + B)) \rightarrow H^i(X, O_X(K_X + mL + B)) \]

are surjective.

An interesting consequence of this involves multiplication maps of globally generated adjoint line bundles. When \( B \) is globally generated, this is the statement of [S, Thm. 1.8.4].

**Corollary 4.4.** Let \( B \) be a nef and abundant line bundle on \( X \) such that the adjoint bundle \( L := K_X + B \) is globally generated. Then \( mL \) is projectively normal for all \( m \geq n + 2 \) and the section ring \( R_L = \bigoplus_{m \geq 0} H^0(mL) \) is generated by \( \bigoplus_{m \leq n+2} H^0(mL) \).

In particular, if \( L \) is also ample then \( mL \) is very ample for \( m \geq n + 2 \). This can be shown directly by using Castelnuovo–Mumford regularity.
**Proof of Corollary 4.4.** Corollary 4.3 implies that, for all $m \geq n + 2$, we have the surjectivity of the multiplication map

$$H^0(L) \otimes H^0(mL) \rightarrow H^0((m + 1)L),$$

which implies the generation statement. By iteration we obtain the surjectivity of the map

$$H^0(L)^{\otimes k} \otimes H^0(mL) \rightarrow H^0((m + k)L)$$

for all $k \geq 1$, which has as a special consequence the projective normality of $mL$.

For completeness, note that the statement of Corollary 4.3, at least for $B = \mathcal{O}_X$, holds also for higher direct images of canonical bundles.

**Proposition 4.5.** Let $X$ and $Y$ be projective varieties, with $X$ smooth and $Y$ of dimension $n$, and let $f: X \rightarrow Y$ be a surjective morphism. Consider a globally generated line bundle $L$ on $Y$. Then, for all $m \geq n + 2$ and all $i, j \geq 0$, the cup product maps

$$H^0(Y, L) \otimes H^i(Y, R^if_*\omega_X \otimes \mathcal{O}_Y((m - 1)L)) \rightarrow H^i(Y, R^if_*\omega_X \otimes \mathcal{O}_Y(mL))$$

are surjective.

**Proof.** The proof goes along the same lines as the proof of Theorem 4.1. We use the morphism $g: Y \rightarrow Z$ induced by $L$ and the corresponding Koszul complex on $Z$. The extra thing to note is that the vanishing

$$H^k(Z, R^ig_*R^if_*\omega_X \otimes \mathcal{O}_Z(l)) = 0 \quad \text{for all} \quad k, l > 0$$

still holds by [K2, Thm. 3.4].

One also obtains a similar weakening of the hypotheses under which the geometric effective Nullstellensatz, [EL, Thm. (iii)] (cf. also [L2, Thm. 10.5.8]) holds, by plugging the statement of Theorem 4.1 into the original proof of [EL, Thm. (iii)].

**Corollary 4.6 (Geometric effective Nullstellensatz).** Let $X$ be a smooth projective variety, $\mathfrak{a} \subset \mathcal{O}_X$ an ideal sheaf, and $L$ an ample line bundle on $X$ such that $L \otimes \mathfrak{a}$ is globally generated—say, by sections $g_j \in H^0(L \otimes \mathfrak{a})$. Consider also a nef and abundant line bundle $B$ on $X$. Then, for all $m \geq n + 2$, if a section

$$g \in H^0(X, \mathcal{O}_X(K_X + mL + B))$$

vanishes to order at least $(n + 1) \cdot \deg L X$ at a general point of each distinguished subvariety of $\mathfrak{a}$, then $g$ can be expressed as a linear combination $\sum h_jg_j$, where $h_j \in H^0(X, \mathcal{O}_X(K_X + (m - 1)L + B))$.

Recall that this means the following: If $f: Y \rightarrow X$ is the normalized blow-up of $X$ along $\mathfrak{a}$ and if $\mathfrak{a} \cdot \mathcal{O}_Y = \mathcal{O}_Y(-\sum a_iE_i)$, then the distinguished subvarieties of $\mathfrak{a}$ are the images of the $E_i$ in $X$ (cf. [EL, Sec. 2]).
