DEFORMING CURVES IN JACOBIANS TO NON-JACOBIANS II:
CURVES IN \( C^{(e)}, 3 \leq e \leq g - 3 \)

E. IZADI

INTRODUCTION

This is a second paper where we introduce deformation theory methods which can be applied to finding curves in families of principally polarized abelian varieties (ppav) containing jacobians. One of our motivations for finding interesting and computationally tractable curves in ppav is to solve the Hodge conjecture for the primitive cohomology of the theta divisor which we explain below. For other motivations we refer to the prequel [1] to this paper.

Let \((A, \Theta)\) be a ppav over \(\mathbb{C}\) of dimension \(g \geq 4\) such that \(\Theta\) is smooth. Since any abelian variety (over \(\mathbb{C}\)) is isogenous to such an abelian variety, the Hodge conjectures for arbitrary abelian varieties are equivalent to the Hodge conjectures for principally polarized abelian varieties with smooth theta divisors.

The primitive part \(K(\Theta, \mathbb{Q})\) of the cohomology of \(\Theta\) can be defined as the kernel of the map \(H^{g-1}(\Theta, \mathbb{Q}) \rightarrow H^{g+1}(A, \mathbb{Q})\) obtained by Poincaré Duality from push-forward on homology. The space \(K(\Theta, \mathbb{Q})\) defines a Hodge substructure of the cohomology of \(\Theta\) of level \(g - 3\) (see page 562 of [8]; the proof there works also for \(g > 4\)). The generalized Hodge conjecture then predicts that there is a family of curves in \(\Theta\) such that \(K(\Theta, \mathbb{Q})\) is contained in the image of its Abel-Jacobi map. The Abel-Jacobi map for a family of curves can be defined as follows.

Let \(\mathcal{C} \rightarrow S\) be a family of curves with \(S\) smooth, complete and irreducible of dimension \(d\) such that there is a diagram

\[
\begin{array}{ccc}
\mathcal{C} & \xrightarrow{q} & \Theta \\
p & \downarrow & \\
S & & 
\end{array}
\]

The Abel-Jacobi map for this family of curves is by definition $AJ := q_* p^* : H^{2d-(g-3)}(S, \mathbb{Q}) \to H^{g-1}(\Theta, \mathbb{Q})$. The image of the Abel-Jacobi map defines a Hodge substructure of level $\leq g-3$ of the cohomology of $\Theta$.

For abelian fourfolds one interesting family of curves is the family of Prym-embedded curves in $\Theta$ and it is proved in [8] that it does give a solution to the Hodge conjecture for $K(\Theta, \mathbb{Q})$. In dimension $\geq 6$ there are no known families of interesting curves in the theta divisor of a general ppav.

Let us briefly explain our methods, similar to [5]. After identifying $JC = \text{Pic}^0 C$ with $A := \text{Pic}^{g-1} C$ by tensoring with a fixed invertible sheaf of degree $g-1$, Riemann’s theta divisor is

$$\Theta := \{ \mathcal{L} \in \text{Pic}^{g-1} C : h^0(\mathcal{L}) > 0 \}.$$

Consider a subvariety $X$ of $A$ contained in “many” translates $\Theta_a$ of $\Theta$. As in [5], for each such translate $\Theta_a$, we have a map

$$\nu_a : H^1(T_A) \to H^1(\mathcal{I}_{Z_{g-1}}(\Theta_a)|_X),$$

obtained from Green’s exact sequence ([4], see Section 3 below) which factors through the first order obstruction map

$$\nu : H^1(T_A) \to H^1(N_{X/JC})$$

where $N_{X/A}$ is the normal sheaf to $X$ in $A$(see Section 2). Hence, if $\nu_a(\eta)$ is not zero for some $a$, so is $\nu(\eta)$.

The main difference between the method used here and that of [5] is in Section 5 below which is more difficult for $e > 2$ and is where we need some assumptions of genericity on $X$.

We apply the above to families of curves in jacobians which are natural generalizations of Prym-embedded curves in tetragonal jacobians. More precisely, let $C$ be a non-hyperelliptic curve of genus $g$ with a $g^1_d$ (a pencil of degree $d$). Define

$$X_e(g^1_d) := \{ D_e : \exists D \in C^{(d-e)} \text{ such that } D_e + D \in g^1_d \} \subset C^{(e)}$$

where $2 \leq e \leq d$ and $C^{(e)}$ is the $e$-th symmetric power of $C$ (see Section 1 below for the precise definition). We map $X := X_e(g^1_d)$ and $C^{(e)}$ to $C^{(g-1)}$ and then to $A$ by adding a fixed divisor $q := \sum_{i=1}^{g-1-e} q_i$. If $d \geq e + 1$, the map is non-constant on $X$. We call $W_e + q$ the image of $C^{(e)}$ in $A$ via this map. Given a one-parameter infinitesimal deformation of the jacobian of $C$ normal to
the jacobian locus $J_g$ we ask when the curve $X$ deforms with it. Let $Z_{g-1} \subset C^{(g-1)}$ be the locus where the map

$$\rho : C^{(g-1)} \longrightarrow \Theta \subset A$$

$$D \longmapsto \mathcal{O}_C(D)$$

fails to be an isomorphism and let $Z_q \subset C^{(e)}$ be the locus defined by the exactness of the sequence

$$N_{W_{e+q}/A|_{C^{(e)}}} \longrightarrow N_{\Theta/A|_{C^{(e)}}} = \mathcal{O}_{C^{(e)}}(\Theta) \longrightarrow \mathcal{O}_{Z_q}(\Theta) \longrightarrow 0.$$ We prove the following

**Theorem 0.1.** Assume $3 \leq e \leq g - 3$, for all $e' \leq e$ the curve $X_{e'}(g_4^1)$ is irreducible and reduced and the set of $q$ for which $X \cap Z_{g-1} \neq X \cap Z_q$ has dimension at most $g-e-3$. If $X_e(g_4^1)$ deforms out of $J_g$ then

- either $h^0(g_4^1) = e$ and $d = 2e$
- or $h^0(g_4^1) = e + 1$ and $d = 2e + 1$.

By Appendix 8.2 below, for $(C, L)$ in a non-empty open subset of the (irreducible) Hurwitz scheme of smooth curves with maps of degree $d$ to $\mathbb{P}^1$ (with simple ramification) the hypotheses of the theorem are satisfied. In case $e = 2$, we proved this result in [5] without the assumptions of genericity. We expect that for $e > 2$ the result will still hold for reducible curves but non-reduced curves might deform in directions which are contained in the intersection of the spans, in $S^2 H^1(\mathcal{O}_A) \subset H^1(\mathcal{O}_A)^{\otimes 2} \cong H^1(T_A)$ of the divisors parametrized by the curve $X$ (this intersection is empty for reduced curves but could be non-empty for non-reduced curves).

In the case $e = 2, d = 4$, the curve $X$ is a Prym-embedded curve (see Recillas [13]), hence deforms out of $J_g$ into the locus of Prym varieties.

As explained in Section 7, Theorem 0.1 shows that when $3 \leq e \leq g - 3$ the most interesting cases in which $X$ will possibly deform out of $J_g$ are those in which $C$ is bielliptic, $e$ any integer between 3 and $g - 3$ or $C$ is any curve of genus $g$ between 6 and 10, $e = 3$ and $L \subset g_6^2$. In both these cases, it is likely that the curve $X$ will deform out of $J_g$. Although jacobians of bielliptic curves form a subvariety of dimension $2g - 2$ of $J_g$, the curves obtained from bielliptic curves will likely deform to large families of ppav: such a situation is analogous to the case of tetragonal jacobians of dimension $\geq 7$ where the curve $X_2(g_4^1)$ deforms to a general Prym but does NOT deform to a general jacobian.
So we have some families of curves (including any $X$ with $e = g - 2$) which could possibly deform to non-jacobians. We need a different approach to prove that higher order obstructions to deformations vanish: this will be presented in detail in the forthcoming paper [6] and the idea behind it is the following. For each $\Theta_a$ containing $X$, one has the map of cohomology groups of normal sheaves

$$H^1(N_{X/JC}) \to H^1(N_{\Theta_a/JC}|_X) = H^1(\mathcal{O}_X(\Theta_a))$$

whose kernel contains all the obstructions to the deformations of $X$ since we will only consider algebraizable deformations of $JC$ for which the obstructions to deforming $\Theta_a$ vanish. If one can prove that the intersection of these kernels is the image of the first order algebraizable deformations of $JC$, i.e., the image of $S^2H^1(\mathcal{O}_C) \subset H^1(T_{JC})$, it will follow that the only obstructions to deforming $X$ with $JC$ are the first order obstructions.

Finally, we would like to mention that from curves one can obtain higher-dimensional subvarieties of an abelian variety. For a discussion of this we refer the reader to [7].

Plan of the paper: In Section 1 we define the curves $X_e(L)$ via their ideals for which we write down a concrete workable resolution. We compute their genus, define their maps to $A$ and prove a useful lemma about divisors parametrized by $X_{e+1}(L)$ and $X_{e+2}(L)$. In Section 2 we define the first order obstruction map $\nu_e : S^2H^1(\mathcal{O}_C) \to H^1(N_{W_e/A}|_X)$ which we use to prove Theorem 0.1. In Section 3 we compute the translates $\Theta_a$ of $\Theta$ containing $X$ and show how we can “replace” $\nu_e$ by the collection of maps $S^2H^1(\mathcal{O}_C) \to H^1(I_{Z_g-1\cap X-a}(\Theta))$. Our method will consist in finding when these maps can have non-trivial kernels. In Section 4 we decompose these maps into compositions of $S^2H^1(\mathcal{O}_C) \to H^0(\mathcal{O}_{Z_g-1\cap X-a}(\Theta))$ and $H^0(\mathcal{O}_{Z_g-1\cap X-a}(\Theta)) \to H^1(I_{Z_g-1\cap X-a}(\Theta))$ which we then analyze separately in Sections 5 and 6 respectively. In Section 5 we prove that for any $\eta \in S^2H^1(\mathcal{O}_C) \setminus H^1(T_C)$, there exists a translate $\Theta_a$ of $\Theta$ containing $X$ such that $\eta$ is not in the kernel of $S^2H^1(\mathcal{O}_C) \to H^0(\mathcal{O}_{Z_g-1\cap X-a}(\Theta))$. In Section 6 we prove that for “almost all” $\Theta_a$ containing $X$, the coboundary map $H^0(\mathcal{O}_{Z_g-1\cap X-a}(\Theta)) \to H^1(I_{Z_g-1\cap X-a}(\Theta))$ is injective unless $d = 2e$ and $h^0(L) = e$ or $d = 2e + 1$ and $h^0(L) = e + 1$ which proves Theorem 0.1. In Section 7 we describe the consequences of Theorem 0.1. Finally, we gather some useful technical results in the Appendix.

Notation and Conventions

We will denote linear equivalence of divisors by $\sim$. 
DEFORMING CURVES IN JACOBIANS TO NON-JACOBIANS II: CURVES IN $C^{(e)}, 3 \leq e \leq g - 3$

For any divisor or coherent sheaf $D$ on a scheme $X$, denote by $h^i(D)$ the dimension of the cohomology group $H^i(D) = H^i(X, D)$. For any subscheme $Y$ of $X$, we will denote by $\mathcal{I}_Y$ the ideal sheaf of $Y$ in $X$ and by $N_{Y/X}$ the normal sheaf of $Y$ in $X$. When there is no ambiguity we drop the subscript $X$ from $\mathcal{I}_Y$ or $N_{Y/X}$. The tangent sheaf of $X$ will be denoted by $T_X := \text{Hom}(\Omega^1_X, \mathcal{O}_X)$ and the dualizing sheaf of $X$ by $\omega_X$. By the genericity of any property on $X$ we mean genericity on every irreducible component.

We let $C$ be a smooth nonhyperelliptic curve of genus $g$ over the field $\mathbb{C}$ of complex numbers. For any positive integer $n$, denote by $C^{(n)}$ the $n$-th symmetric power of $C$. Note that $C^{(n)}$ parametrizes the effective divisors of degree $n$ on $C$.

We denote by $K$ an arbitrary canonical divisor on $C$. Since $C$ is not hyperelliptic, its canonical map $C \to |K|^{\ast}$ is an embedding and throughout this paper we identify $C$ with its canonical image. For a divisor $D$ on $C$, we denote by $\langle D \rangle$ its span in $|K|^{\ast} = \mathbb{P}H^0(\omega_C)^{\ast} = \mathbb{P}H^1(\mathcal{O}_C)$. Since we will mostly work with the Picard group $\text{Pic}^{g-1}C$ of invertible sheaves of degree $g - 1$ on $C$, we put $A := \text{Pic}^{g-1}C$. Let $\Theta$ denote the natural theta divisor of $A$, i.e.,

$$\Theta := \{ \mathcal{L} \in A : h^0(\mathcal{L}) > 0 \}.$$ 

The multiplicity of $\Theta$ at $\mathcal{L} \in \Theta$ is $h^0(\mathcal{L})$ ([2] Chapter VI p. 226). So the singular locus of $\Theta$ is

$$\text{Sing}(\Theta) := \{ \mathcal{L} \in A : h^0(\mathcal{L}) \geq 2 \}.$$ 

There is a map

$$\text{Sing}_2(\Theta) \longrightarrow |I_2(C)|$$

$$\mathcal{L} \mapsto \mathcal{Q}(\mathcal{L}) := \cup_{D \in |\mathcal{L}|} \langle D \rangle$$

where $\text{Sing}_2(\Theta)$ is the locus of points of order 2 on $\Theta$ and $|I_2(C)|$ is the linear system of quadrics containing the canonical curve $C$. This map is equal to the map sending $\mathcal{L}$ to the (quadric) tangent cone to $\Theta$ at $\mathcal{L}$ and its image $\mathcal{Q}$ generates $|I_2(C)|$ (see [4] and [14]). Any $\mathcal{Q}(\mathcal{L}) \in \mathcal{Q}$ has rank $\leq 4$. The singular locus of $\mathcal{Q}(\mathcal{L})$ cuts $C$ in the sum of the base divisors of $|\mathcal{L}|$ and $|\omega_C \otimes \mathcal{L}^{-1}|$. The rulings of $\mathcal{Q}$ cut the divisors of the moving parts of $|\mathcal{L}|$ and $|\omega_C \otimes \mathcal{L}^{-1}|$ on $C$ (see [11]).

For any divisor or invertible sheaf $a$ of degree 0 and any subscheme $Y$ of $A$, we let $Y_a$ or $Y + a$ denote the translate of $Y$ by $a$. By a $g^r_d$ we mean a (not necessarily complete) linear system of degree $d$ and dimension $r$. We call $W^r_d$ the subvariety of $\text{Pic}^dC$ parametrizing invertible sheaves $\mathcal{L}$ with $h^0(\mathcal{L}) > r$. 
For any effective divisor $E$ of degree $e$ on $C$ and any positive integer $n \geq e$, let $C_E^{(n-e)} \subset C^{(n)}$ be the image of $C^{(n-e)}$ in $C^{(n)}$ by the morphism $D \mapsto D + E$. For any divisor $E = \sum_{i=1}^{r} n_i t_i$ on $C$, let $C_E^{\text{div}}$ denote the divisor $\sum_{i=1}^{r} n_i C_i^{(n-1)}$ on $C^{(n)}$. For a linear system $L$ on $C$, we denote by $C_L^{\text{div}}$ any divisor $C_E^{\text{div}} \subset C^{(n)}$ with $E \in L$.

By infinitesimal deformation we always mean flat first order infinitesimal deformation.

1. The curve $X := X_{\langle g_1 \rangle}$ and its useful properties

Suppose $2 \leq e \leq g - 1$ and let $L$ be a pencil of degree $d \geq e + 2$ on $C$. We would like to define a curve $X$ whose underlying set will be

$$\{ D_e : \exists D \in C^{(d-e)} \text{ such that } D_e + D \in L \}.$$

If $L$ contains reduced divisors, then $X$ is reduced and can be defined by the above set. If $L$ does not contain reduced divisors then we need to define a scheme structure on $X$. Although we suppose $X$ integral in this paper, we will define it in general since the definition is simple in the general case. Furthermore, we define the curve by its ideal sheaf whose description we will use later on. We do this in such a way that our nonreduced curves will be flat limits of the reduced ones. Note that the restriction $d \geq e + 2$ avoids trivial cases where either the maps $X \to A$ are constant or the cohomology class of the image $\overline{X}$ of $X$ is equal to the minimal class in which case we know that $\overline{X}$ does not deform out of the jacobian locus $\Pi$.

Let $W(L) \subset H^0(L)$ be the vector subspace whose projectivization is $L \subset |L|$. The underlying set of $X$ is the subset of $C^{(e)}$ where the elements of $W(L)$ are dependent. A scheme structure can be defined on this set in the following way. Let $D^e \subset C^{(e)} \times C$ be the universal divisor and let $q_e$ and $p_e$ be the first and second projections from $C^{(e)} \times C$ onto $C^{(e)}$ and $C$ respectively. Then the global evaluation of sections of $\mathcal{O}_C(L)$ on divisors of degree $e$ is the map

$$H^0(L) \otimes \mathcal{O}_{C^{(e)}} \longrightarrow V_e^e := q_{e*}(p_{e*}\mathcal{O}_C(L)|_{D^e})$$

obtained by push-forward via $q_e$ from the evaluation map

$$p_{e*}\mathcal{O}_C(L) \longrightarrow p_{e*}\mathcal{O}_C(L)|_{D^e}.$$

So $X$ is the locus where the evaluation map $W(L) \otimes \mathcal{O}_{C^{(e)}} \to V_e^e$ has rank $\leq 1$. Therefore, since $X$ is of (the expected) pure dimension 1, by Eagon and Northcott \[2\] Theorem 2 page 201, there
is an exact sequence
\[(1.2) \hspace{1cm} 0 \rightarrow \Lambda^e V_L^e \otimes S^e W(L) \rightarrow \ldots \rightarrow \Lambda^4 V_L^e \otimes S^2 W(L) \rightarrow \Lambda^3 V_L^e \otimes W(L) \rightarrow \Lambda^2 V_L^e \rightarrow \mathcal{I}_{X/C(e)} \rightarrow 0.\]

Since our construction can be done globally in families, we see that our non-reduced curves \(X\) are indeed flat limits of reduced curves \(X\).

The natural morphism \(C \rightarrow \mathbb{P}^1\) obtained from \(L\) gives a morphism \(X \rightarrow \mathbb{P}^1\) and, using the Hurwitz formula, one sees immediately that \(X\) has arithmetic genus
\[g_X = -\binom{d}{e} + (g - 1 + d)\binom{d - 2}{e - 1} + 1.\]

This works at least when \(X\) is smooth. When \(X\) is not smooth, we obtain the arithmetic genus by specialization from the smooth case.

1.1. Having defined \(X\) in \(C(e)\), we define the curve \(\overline{X}\) that we are really interested in as its image in \(A\) up to translation. For this we first choose \(g - e - 1\) general points \(p_1, \ldots, p_{g-e-1}\) in \(C\) and map \(C(e)\) to \(C(g-1)\) and \(A\) by the respective morphisms
\[\phi_p : C(e) \rightarrow C(g-1), \quad \psi_p : C(e) \rightarrow A\]
\[D_e \mapsto D_e + \sum_{i=1}^{g-e-1} p_i, \quad D_e \mapsto \mathcal{O}_C(D_e + \sum_{i=1}^{g-e-1} p_i).\]

The first map is an embedding and the second map is a rational resolution of its image which is a determinantal variety. The fibers of \(\psi_p\) are the complete linear systems in \(C(e)\). Therefore, in particular, if we let \(W_e\) be the image of \(C(e)\) in \(A\), then \(\psi_p_*(\mathcal{O}_C(e)) = \mathcal{O}_{W_e}\). We define \(\overline{X}\) to be the curve whose ideal is \(\psi_p_*(\mathcal{I}_{X/C(e)})\). It immediately follows that if \(X\) is integral, then so is \(\overline{X}\). Furthermore, it is the flat limit of general curves \(\overline{X}\) in jacobians of general curves with \(g_d^1\). Replacing \(X\) by \(X_{d-e}(L)\) if necessary, we will assume that \(d \geq 2e\). We have the following.

**Lemma 1.1.** Suppose \(e \leq g - 2\) and \(L\) contains reduced divisors. Then

1. there are divisors \(D \in X_{e+1}(L)\) such that \(h^0(D) = 1\),
2. assume \(e \leq g - 3\) and
   1. either \(d \geq 2e + 2\),
   2. or \(d = 2e + 1, h^0(L) \leq e\),
   3. or \(d = 2e, h^0(L) \leq e - 1\);
then there are divisors \(D \in X_{e+2}(L)\) such that \(h^0(D) = 1\).
Proof. If \( d \geq 2g - 2 \), then a general divisor of \( L \) is reduced and spans at least a hyperplane in the canonical space of \( C \). So we can choose a subdivisor of degree \( e + 1 \) (resp. \( e + 2 \) if \( e \leq g - 3 \)) of it which spans a linear subspace of dimension \( e \) (resp. \( e + 1 \)) of \( |K|^* \) and hence satisfies the lemma. If \( d \leq 2g - 3 \), then, by Clifford’s Theorem, since \( C \) is not hyperelliptic, we have \( 2(h^0(L) - 1) < d \), hence \( h^1(L) < g - \frac{d}{2} \leq g - e \). So \( h^1(L) \leq g - e - 1 \) and a general divisor of \( L \) is reduced and spans a linear subspace of \( |K|^* \) of dimension at least \( e \). Therefore it has a subdivisor of degree \( e + 1 \) which spans a linear space of dimension \( e \) and hence satisfies the first part of the lemma. For the second part, the assumptions in conjunction with Clifford’s Theorem imply that \( h^1(L) \leq g - e - 2 \) and an analogous reasoning proves the second part. \( \square \)

2. The first order obstruction map

2.1. From now on in the rest of the paper we shall always assume that \( X \) (hence \( \overline{X} \)) is integral, i.e., reduced and irreducible. It is immediate that the irreducibility of \( X \) implies that \( L \) has no base points. Note that the converse to this is not true as is easily seen by assuming that \( C \) maps nontrivially to a curve of positive genus and taking \( L \) to be the inverse image of a pencil on the curve of lower positive genus.

Recall that we also assume \( d \geq 2e \), and, by Lemma 1.1, a general \( D_e \in X \) satisfies \( h^0(D_e) = 1 \) so that the map \( X \rightarrow \overline{X} \) is birational.

2.2. Since \( \overline{X} \) is reduced, the obstructions to deformations of \( \overline{X} \) with \( A \) live in \( \text{Ext}^1_{\overline{X}}(I_{\overline{X}}/A/I_{\overline{X}}^2, O_{\overline{X}}) \) (see \( [9] \) Lemma 2.13 page 33 and Proposition 2.14 page 34). We have the usual map

\[
I_{\overline{X}}/A/I_{\overline{X}}^2 \rightarrow \Omega^1_{\overline{X}}
\]

from which we obtain the map of exterior groups

\[
H^1(T_{\overline{X}}) \rightarrow \text{Ext}^1_{\overline{X}}(I_{\overline{X}}/A/I_{\overline{X}}^2, O_{\overline{X}}).
\]

Composing this with restriction

\[
H^1(T_A) \rightarrow H^1(T_{\overline{X}}),
\]

we obtain the first order obstruction map

\[
\nu : H^1(T_A) \rightarrow \text{Ext}^1_{\overline{X}}(I_{\overline{X}}/A/I_{\overline{X}}^2, O_{\overline{X}}).
\]

Given an infinitesimal deformation \( \eta \in H^1(T_A) \), the curve \( X \) deforms with \( A \) in the direction of \( \eta \) if and only if \( \nu(\eta) = 0 \).
2.3. The local to global spectral sequence for the exterior sheaves of $T_{X/A}/T^2_{X/A}$ provides the exact sequence

$$0 \longrightarrow H^1(N_{X/A}) \longrightarrow Ext^1(T_{X/A}/T^2_{X/A}, O_X) \longrightarrow H^0(Ext^1(T_{X/A}/T^2_{X/A}, O_X)).$$

The composition

$$H^1(T_A) \longrightarrow Ext^1(T_{X/A}/T^2_{X/A}, O_X) \longrightarrow H^0(Ext^1(T_{X/A}/T^2_{X/A}, O_X))$$

sends $\eta$ to the obstruction to deform $X$ with it locally. Since $A$ is smooth, every deformation of $A$ is locally trivial and locally $X$ deforms with it trivially. Therefore the image of $\eta$ by the above composition is zero and the obstruction map $\nu$ factors through $H^1(N_{X/A})$:

$$\nu : H^1(T_A) \longrightarrow H^1(N_{X/A}).$$

Alternatively, the dual of the map (2.1) gives us the map of cohomology groups

$$H^1(T_A|X) \longrightarrow H^1(N_{X/A})$$

whose composition with the inclusion $H^1(N_{X/A}) \longrightarrow Ext^1(T_{X/A}/T^2_{X/A}, O_X)$ is $\nu$.

2.4. From the inclusion $X \subset W_e$, we obtain the map

$$N_{X/A} \longrightarrow N_{W_e/A}|X$$

which gives us the map of cohomology groups

$$H^1(N_{X/A}) \longrightarrow H^1(N_{W_e/A}|X).$$

We call $\nu_e$ the composition of this with $\nu$ and the pull-back $H^1(N_{W_e/A}|X) \rightarrow H^1(N_{W_e/A}|X)$ obtained from the surjective morphism $X \rightarrow X$:

$$\nu_e : H^1(T_A) \longrightarrow H^1(N_{W_e/A}|X).$$

If $\nu_e(\eta) \neq 0$, then, a fortiori, $\nu(\eta) \neq 0$. 
2.5. The choice of the polarization $\Theta$ provides an isomorphism $H^1(T_A) \cong H^1(\mathcal{O}_C)^{\otimes 2}$ via which the algebraic (i.e. globally unobstructed) infinitesimal deformations with which $\Theta$ deforms are identified with the elements of the subspace $S^2H^1(\mathcal{O}_C) \subset H^1(\mathcal{O}_C)^{\otimes 2} \cong H^1(T_A)$. Via this identification, the space of infinitesimal deformations of $(A, \Theta)$ as a jacobian is naturally identified with $H^1(T_C) \subset S^2H^1(\mathcal{O}_C)$. The Serre dual of this last map is multiplication of sections

$$S^2H^0(K) \to H^2(2K)$$

whose kernel is the space $I_2(C)$ of degree 2 forms vanishing on the canonical image of $C$. To say that we consider an infinitesimal deformation of $(A, \Theta)$ out of the jacobian locus, means that we consider $\eta \in S^2H^1(\mathcal{O}_C) \setminus H^1(T_C)$ which is therefore equivalent to say that we consider $\eta \in S^2H^1(\mathcal{O}_C)$ such that there is $Q \in I_2(C)$ with $(Q, \eta) \neq 0$. Here we denote by

$$(,): S^2H^0(K) \otimes S^2H^1(\mathcal{O}_C) \to S^2H^1(K) \cong \mathbb{C}$$

the pairing obtained from Serre Duality.

3. Translates of $\Theta$ containing $W_e$ and the obstruction map

To prove our main theorem we use translates of $\Theta$ which contain $W_e$.

**Lemma 3.1.** The subvariety $W_e$ is contained in a translate $\Theta_a$ of $\Theta$ if and only if there exists $\sum q_i \in C^{(g-1)}$ such that $a = \sum p_i - \sum q_i$.

**Proof.** For any points $q_1, \ldots, q_{g-1}$ of $C$, the image of $C^{(e)}$ in $A$ by the corresponding map $\psi_q$ is contained in the divisor $\Theta_{\sum p_i - \sum q_i}$. Conversely, if $W_e$ is contained in a translate $\Theta_a$ of $\Theta$, then we have $h^0(D_e + \sum p_i - a) > 0$, for all $D_e \in C^{(e)}$. Equivalently, for all $D_e \in C^{(e)}$, we have $h^0(K + a - \sum p_i - D_e) > 0$, i.e., $h^0(K + a - \sum p_i) \geq e + 1$ and $-a + \sum p_i$ is effective. □

3.1. Choose $a \in \text{Pic}^0C$ such that $W_e \subset \Theta_a$ (i.e., $a = \sum p_i - \sum q_i$ as above). Equivalently $W_e-a \subset \Theta$. Let $\rho : C^{(g-1)} \to \Theta$ be the natural morphism. Then (see [4] (1.20) p. 89) we have the exact sequence

$$0 \to T_{C^{(g-1)}} \to \rho^*T_A \to \mathcal{I}_{Z_{g-1}}(\Theta) \to 0$$

where, as in the Introduction, the scheme $Z_{g-1}$ is the locus where the map $\rho$ fails to be an isomorphism. For the convenience of the reader we mention that the scheme $Z_{g-1}$ is a determinantal
scheme of codimension 2. If \( g \geq 5 \) or if \( g = 4 \) and \( C \) has two distinct \( g_i \)'s, the scheme \( Z_{g-1} \) is reduced and is the scheme-theoretical inverse image of the singular locus of \( \Theta \).

Combining sequence (3.1) with the tangent bundles sequences for \( C^{(e)}_{\sum q_i} \subset C^{(g-1)} \) and \( W_e - a \subset A \), we obtain the commutative diagram with exact rows and columns

\[
\begin{array}{ccc}
0 & \rightarrow & 0 \\
\downarrow & & \downarrow \\
T_{C^{(e)}} & = & T_{C^{(e)}} \\
\downarrow & & \downarrow \\
T_{C^{(g-1)}}|_{C^{(e)}_{\sum q_i}} & \rightarrow & T_A|_{C^{(e)}_{\sum q_i}} \\
\downarrow & & \downarrow \\
T_{Z_{g-1}}(\Theta)|_{C^{(e)}_{\sum q_i}} & \rightarrow & 0 \\
\downarrow & & \downarrow \\
N_{C^{(e)}_{\sum q_i}/C^{(g-1)}} & \rightarrow & N_{W_e - a/A}|_{C^{(e)}_{\sum q_i}} \\
\downarrow & & \downarrow \\
0 & \rightarrow & \mathcal{O}_{C^{(e)}_{\sum q_i}}(\Theta) \rightarrow 0 \\
\downarrow & & \downarrow \\
0 & \rightarrow & 0
\end{array}
\]

where the leftmost horizontal maps are injective if and only if \( h^0(\sum q_i) = 1 \) and the map of sheaves

\[
T_A|_{W_e - a} \rightarrow N_{W_e - a/A}
\]

fails to be surjective on the locus where \( \psi_q \) fails to be an embedding. In \( C^{(e)} \) this locus, which we call \( Z_e \), is locally defined, in the same way as \( Z_{g-1} \), by the maximal minors of the map \( T_{C^{(e)}} \rightarrow T_A|_{C^{(e)}} \).

The support of \( Z_e \) is the subset of \( C^{(e)} \) parametrizing divisors \( D_e \) with \( h^0(D_e) \geq 2 \). The right-hand bottom horizontal map is the pull-back to \( C^{(e)}_{\sum q_i} \) of the map of normal sheaves

\[
N_{W_e - a/A} \rightarrow \mathcal{O}_{W_e - a}(\Theta) = N_{\Theta/A}|_{W_e - a}
\]

whose image is the twist of a sheaf of ideals by \( \mathcal{O}_{W_e - a}(\Theta) \). As in the introduction, we let \( Z_q \) be the subscheme of \( C^{(e)} \) defined by the pull-back of this sheaf of ideals. Note that because the sheaf of ideals contains \( T_{Z_{g-1} \cap C^{(e)}_{\sum q_i}} \), the subscheme \( Z_q \) is contained in \( Z_{g-1} \cap C^{(e)}_{\sum q_i} \). Furthermore, because \( C^{(e)}_{\sum q_i} \rightarrow W_e - a \) is an isomorphism outside \( Z_e \), we have \( Z_q \setminus Z_e = Z_{g-1} \cap C^{(e)}_{\sum q_i} \setminus Z_e \).

3.2. Hypothesis. From now on we will assume that the set of \( q \) for which \( Z_q \cap X_{-a} \neq Z_{g-1} \cap X_{-a} \) has dimension at most \( g - e - 3 \) and we have chosen \( q \) outside of this set, i.e., in such a way that

\[
Z_q \cap X_{-a} = Z_{g-1} \cap X_{-a}.
\]
By Appendix 8.2 this will be the case for all \( q \in C^{(g-1-e)} \) on some open subset of the space of pairs \((C, L)\).

Therefore, restricting the previous diagram to \( X_{-a} \), we obtain

\[
\begin{align*}
T_{C\{\varepsilon\}}|_{X_{-a}} & = T_{C\{\varepsilon\}}|_{X_{-a}} \\
\downarrow & \downarrow \\
T_{C(g-1)}|_{X_{-a}} & \rightarrow T_{A}|_{X_{-a}} \rightarrow I_{Zg-1}(\Theta)|_{X_{-a}} \rightarrow 0 \\
\downarrow & \downarrow \\
N_{C\{\varepsilon\}}|_{C(g-1)}|_{X_{-a}} & \rightarrow NW_{e-a/A}|_{X_{-a}} \rightarrow I_{Zg-1}(\Theta)|_{X_{-a}} \rightarrow 0 \\
\downarrow & \downarrow \\
0 & 0
\end{align*}
\]

So we have the commutative diagram

\[
\begin{array}{ccc}
S^2H^1(O_C) \subset H^1(T_A) & \rightarrow & H^1(T_A|_{X_{-a}}) \rightarrow H^1(I_{Zg-1}(\Theta)|_{X_{-a}}) \\
\| & & \| \\
S^2H^1(O_C) \subset H^1(T_A) & \rightarrow & H^1(N_{W_{e-a/A}}|_{X_{-a}}) \rightarrow H^1(I_{Zg-1}(\Theta)|_{X_{-a}}).
\end{array}
\]

Translation by \( a \) induces the identity on \( H^1(T_A) \) and isomorphisms

\[
\begin{align*}
H^1(T_A|_{X_{-a}}) & \cong H^1(T_A|X) \\
H^1(N_{W_{e-a/A}}|_{X_{-a}}) & \cong H^1(N_{W_{e/A}}|X)
\end{align*}
\]

so that the kernel of

\[
\nu_e : S^2H^1(O_C) \rightarrow H^1(N_{W_{e/A}}|X)
\]

is equal to the kernel of the map

\[
S^2H^1(O_C) \rightarrow H^1(N_{W_{e-a/A}}|_{X_{-a}})
\]

obtained from \( \nu_e \) by translation. Therefore the previous diagram proves the following theorem.

**Theorem 3.2.** The kernel of the map

\[
\nu_e : S^2H^1(O_C) \rightarrow H^1(N_{W_{e/A}}|X)
\]

is contained in the kernel of the map obtained from the above

\[
S^2H^1(O_C) \rightarrow H^1(I_{Zg-1}(\Theta)|_{X_{-a}})
\]

for all \( a \) such that \( \Theta_a \) contains \( W_e \) and \( Z_q \cap X_{-a} = Z_{g-1} \cap X_{-a} \).
A fortiori, the kernel of $\nu_e$ is contained in the kernel of the composition

$$S^2H^1(O_C) \rightarrow H^1(I_{Z_{g-1}}(\Theta)|_{X-a}) \rightarrow H^1(I_{Z_{g-1}\cap X-a}(\Theta)).$$

We shall prove that for any $\eta \in S^2H^1(O_C) \setminus H^1(T_C)$, there exists $a$ such that $\Theta_a$ contains $W_e$ and the image of $\eta$ in $H^1(I_{Z_{g-1}\cap X-a}(\Theta))$ is nonzero unless

- either $e = h^0(L)$ and $d = 2e$,
- or $e = 2h^0(L)$ and $d = 2e + 1$.

4. The kernel of the map $S^2H^1(O_C) \rightarrow H^1(I_{Z_{g-1}\cap X-a}(\Theta))$

4.1. The above map is equal to the composition

$$S^2H^1(O_C) \rightarrow H^1(I_{Z_{g-1}}(\Theta)) \rightarrow H^1(I_{Z_{g-1}}(\Theta)|_{X-a}) \rightarrow H^1(I_{Z_{g-1}\cap X-a}(\Theta)).$$

From the usual exact sequence

$$0 \rightarrow I_{Z_{g-1}}(\Theta) \rightarrow O_{C^{(e)}}(\Theta) \rightarrow O_{Z_{g-1}}(\Theta) \rightarrow 0$$

we obtain the embedding

$$H^0(O_{Z_{g-1}}(\Theta)) \hookrightarrow H^1(I_{Z_{g-1}}(\Theta)).$$

By [4] p. 95, the image of $S^2H^1(O_C)$ in $H^1(I_{Z_{g-1}}(\Theta))$ is contained in $H^0(O_{Z_{g-1}}(\Theta))$. Using the commutative diagram with exact rows

$$\begin{array}{ccccccc} 0 & \rightarrow & I_{Z_{g-1}}(\Theta) & \rightarrow & O_{C^{(g-1)}}(\Theta) & \rightarrow & O_{Z_{g-1}}(\Theta) & \rightarrow & 0 \\ \downarrow & & \downarrow & & \downarrow & & \downarrow \\ 0 & \rightarrow & I_{Z_{g-1}\cap X-a}(\Theta) & \rightarrow & O_{X-a}(\Theta) & \rightarrow & O_{Z_{g-1}\cap X-a}(\Theta) & \rightarrow & 0, \end{array}$$

Composition (4.1) is also equal to the composition

$$S^2H^1(O_C) \rightarrow H^0(O_{Z_{g-1}}(\Theta)) \rightarrow H^0(O_{Z_{g-1}\cap X-a}(\Theta)) \rightarrow$$

$$\rightarrow H^1(I_{Z_{g-1}\cap X-a}(\Theta)).$$

By [4] p. 95 the first map is the following

$$S^2H^1(O_C) \rightarrow H^0(O_{Z_{g-1}}(\Theta))$$

$$\sum a_{ij} \frac{\partial^2}{\partial z_i \partial z_j} \mapsto \sum a_{ij} \frac{\partial^2}{\partial z_i \partial z_j} |_{Z_{g-1}}.$$
4.2. We will investigate the kernel of the composition of the first two maps $S^2H^1(\mathcal{O}_C) \rightarrow H^0(\mathcal{O}_{Z_{g-1}}(\Theta)) \rightarrow H^0(\mathcal{O}_{Z_{g-1}\cap X_{-a}}(\Theta)) \rightarrow H^1(\mathcal{I}_{Z_{g-1}\cap X_{-a}}(\Theta))$ separately. The kernel of $S^2H^1(\mathcal{O}_C) \rightarrow H^0(\mathcal{O}_{Z_{g-1}\cap X_{-a}}(\Theta))$ and that of the coboundary map $H^0(\mathcal{O}_{Z_{g-1}\cap X_{-a}}(\Theta)) \rightarrow H^1(\mathcal{I}_{Z_{g-1}\cap X_{-a}}(\Theta))$ separately. The kernel of $S^2H^1(\mathcal{O}_C) \rightarrow H^0(\mathcal{O}_{Z_{g-1}\cap X_{-a}}(\Theta))$ is contained in (with equality if and only if $Z_{g-1}\cap X_{-a}$ is reduced) the annihilator of the quadrics of rank $\leq 4$ which are the tangent cones to $\Theta$ at the points of $Z_{g-1}\cap X_{-a}$.

5. The kernel of the map $S^2H^1(\mathcal{O}_C) \rightarrow H^0(\mathcal{O}_{Z_{g-1}\cap X_{-a}}(\Theta))$

5.1. An effective divisor $\sum_{i=1}^{g-1-\epsilon} q_i \in C^{(g-1-\epsilon)}$ gives the embedding of $X$ in $C^{(g-1-\epsilon)}$ defined by $D_e \hookrightarrow D_e + \sum_{i=1}^{g-1-\epsilon} q_i$. The union of the images of these maps is a scheme, denoted $X + C^{(g-1-\epsilon)} \subset C^{(g-1-\epsilon)}$ whose intersection with $Z_{g-1}$ is the union of the schemes $Z_{g-1}\cap X_{-a}$ as $a = \sum p_i - \sum q_i$ varies. To say that $\eta$ is in the kernel of the composition

$$S^2H^1(\mathcal{O}_C) \rightarrow H^0(\mathcal{O}_{Z_{g-1}}(\Theta)) \rightarrow H^0(\mathcal{O}_{Z_{g-1}\cap X_{-a}}(\Theta))$$

for every $a$, means that $\eta$ is in the kernel of the map

$$S^2H^1(\mathcal{O}_C) \rightarrow H^0(\mathcal{O}_{Z_{g-1}}(\Theta)) \rightarrow H^0(\mathcal{O}_{Z_{g-1}\cap X + C^{(g-1-\epsilon)}}(\Theta)).$$

Since $X$ is reduced, $X + C^{(g-1-\epsilon)}$ is also the union of all $C^{(g-1-\epsilon)}_E$ with $E \in X$. So we see that the above is also equivalent to $\eta$ being in the kernel of all the maps

$$S^2H^1(\mathcal{O}_C) \rightarrow H^0(\mathcal{O}_{Z_{g-1}}(\Theta)) \rightarrow H^0(\mathcal{O}_{Z_{g-1}\cap C^{(g-1-\epsilon)}_E}(\Theta))$$

for all points $E \in X$.

5.2. We compute the kernel of the map

$$S^2H^1(\mathcal{O}_C) \rightarrow H^0(\mathcal{O}_{Z_{g-1}}(\Theta)) \rightarrow H^0(\mathcal{O}_{Z_{g-1}\cap C^{(f)}_D}(\Theta))$$

for $1 \leq f \leq g-1$ and $D$ a divisor of degree $g-1-f$ such that $h^0(D) = 1$. We shall later assume $D \in X$. Recall that by Lemma [1.1] for a general $D \in X$, we have $h^0(D) = 1$. 

where $\{z_i\}$ is a system of coordinates on $A$ and $\sigma$ is a theta function with divisor of zeros equal to $\Theta$. So we have the following description

$$S^2H^1(\mathcal{O}_C) \rightarrow H^0(\mathcal{O}_{Z_{g-1}}(\Theta)) \rightarrow H^0(\mathcal{O}_{Z_{g-1}\cap X_{-a}}(\Theta)) \rightarrow H^1(\mathcal{I}_{Z_{g-1}\cap X_{-a}}(\Theta))$$

\[\sum a_{ij} \frac{\partial^2}{\partial z_i \partial z_j} \rightarrow \sum a_{ij} \frac{\partial^2 \sigma}{\partial z_i \partial z_j} \mid_{Z_{g-1}} \rightarrow \sum a_{ij} \frac{\partial^2 \sigma}{\partial z_i \partial z_j} \mid_{Z_{g-1}\cap X_{-a}} \rightarrow ?\]
Consider the exact sequence
\[ 0 \to T_{C^{(g-1)}}|_{C_D^{(f)}} \to T_A|_{C_D^{(f)}} \to \mathcal{I}_{Z_{g-1}}(\theta)|_{C_D^{(f)}} \to 0 \]
from which it follows that the kernel of the map
\[ H^1(T_A|_{C_D^{(f)}}) = H^1(T_A) = H^1(O_C)^{\otimes 2} \to H^1(\mathcal{I}_{Z_{g-1}}(\theta)|_{C_D^{(f)}}) \]
is the image of \( H^1(T_{C^{(g-1)}}|_{C_D^{(f)}}) \). We have
\[ \mathcal{I}_{Z_{g-1}}(\theta)|_{C_D^{(f)}} \cong \mathcal{I}_{Z_{g-1} \cap C_D^{(f)}}(\theta) \]
if and only if \( Z_{g-1} \cap C_D^{(f)} \) has codimension 2 in \( C_D^{(f)} \). In such a case the kernel of
\[ S^2H^1(O_C) \to H^0(O_{Z_{g-1}}(\Theta)) \to H^0(O_{Z_{g-1} \cap C_D^{(f)}}(\Theta)) \]
is the intersection of the image of \( H^1(T_{C^{(g-1)}}|_{C_D^{(f)}}) \) with \( S^2H^1(O_C) \).

Denote by \( V(D) \) the vector subspace of \( H^1(O_C) = H^0(\omega_C)^* \) whose projectivization is \( (D) \).

**Theorem 5.1.** The image of \( H^1(T_{C^{(g-1)}}|_{C_D^{(f)}}) \) in \( H^1(T_A|_{C_D^{(f)}}) \) is the span of \( H^1(T_C) \subset S^2H^1(O_C) \)
and \( V(D) \otimes H^1(O_C) \). The intersection of this span with \( S^2H^1(O_C) \) is the span of \( H^1(T_C) \) and \( S^2V(D) \).

**Proof.** We first determine the image of \( H^1(T_{C^{(g-1)}}|_{C_D^{(f)}}) \) in \( H^1(T_A|_{C_D^{(f)}}) \) and its intersection with \( S^2H^1(O_C) \). For this we use the diagram
\[ \begin{array}{ccc}
0 & \to & 0 \\
\downarrow & & \downarrow \\
T_C^{(f)} & = & T_C^{(f)} \\
\downarrow & & \downarrow \\
0 \to T_{C^{(g-1)}}|_{C_D^{(f)}} & \to & T_A|_{C_D^{(f)}} \to \mathcal{I}_{Z_{g-1}}(\theta)|_{C_D^{(f)}} \to 0 \\
\downarrow & & \downarrow \\
0 \to N_{C_D^{(f)}/C^{(g-1)}} & \to & N_{C_D^{(f)}/A} \to \mathcal{I}_{Z_{g-1}}(\theta)|_{C_D^{(f)}} \to 0 \\
\downarrow & & \\
0 & & 
\end{array} \]
The map \( H^1(C^{(f)}, T_C^{(f)}) \to H^1(C^{(f)}, T_A|_{C_D^{(f)}}) \) is injective, hence so is the map \( H^1(C^{(f)}, T_C^{(f)}) \to H^1(C^{(f)}, T_{C^{(g-1)}}|_{C_D^{(f)}}) \). Therefore \( H^0(C^{(f)}, T_{C^{(g-1)}}|_{C_D^{(f)}}) \to H^0(C^{(f)}, N_{C_D^{(f)}/C^{(g-1)}}) \) is an isomorphism.
Consider now the composition

\[ H^0(T_{C^{(g-1)}}|_{C_D^{(f)}}) \otimes \mathcal{O}_{C^{(f)}} \longrightarrow T_{C^{(g-1)}}|_{C_D^{(f)}} \longrightarrow N_{C_D^{(f)}|C^{(g-1)}} \]

where the first map is evaluation. Then, because of the isomorphism \( H^0(C^{(f)}, T_{C^{(g-1)}}|_{C_D^{(f)}}) \cong H^0(C^{(f)}, N_{C_D^{(f)}|C^{(g-1)}}) \), this composition can be identified with evaluation of global sections

\[ H^0(C^{(f)}, N_{C_D^{(f)}|C^{(g-1)}}) \otimes \mathcal{O}_{C^{(f)}} \longrightarrow N_{C_D^{(f)}|C^{(g-1)}}. \]

From this we obtain the map

\[ H^0(C^{(f)}, N_{C_D^{(f)}|C^{(g-1)}}) \otimes H^1(\mathcal{O}_{C^{(f)}}) \longrightarrow H^1(N_{C_D^{(f)}|C^{(g-1)}}). \]

Write \( D = \sum_{i=1}^{g-1-f} t_i \). Since \( C_D^{(f)} \) is the complete intersection of the divisors \( C_{t_i}^{(g-2)} \) in \( C^{(g-1)} \), its normal sheaf is isomorphic to \( \bigoplus_{i=1}^{f} \mathcal{O}_{C^{(f)}}(C_{t_i}^{(g-1)}) \). Therefore, using Appendix 6.1 in [5], the above map can be identified with

\[ \bigoplus_{i=1}^{g-1-f} S^{(f)} H^0(t_i) \otimes H^1(\mathcal{O}_C) \longrightarrow \bigoplus_{i=1}^{f} S^{(f)} H^0(t_i) \otimes H^1(t_i) \]

which is onto because each of the maps \( H^1(\mathcal{O}_C) \to H^1(q_i) \) is linear projection which is onto. Therefore, the composition

\[ H^0(T_{C^{(g-1)}}|_{C_D^{(f)}}) \otimes H^1(\mathcal{O}_{C^{(f)}}) \longrightarrow H^1(T_{C^{(g-1)}}|_{C_D^{(f)}}) \longrightarrow H^1(N_{C_D^{(f)}|C^{(g-1)}}) \]

is onto and hence so is

\[ H^1(T_{C^{(g-1)}}|_{C_D^{(f)}}) \longrightarrow H^1(N_{C_D^{(f)}|C^{(g-1)}}). \]

In conclusion we have the exact sequence

\[ 0 \longrightarrow H^1(T_{C^{(f)}}) \longrightarrow H^1(T_{C^{(g-1)}}|_{C_D^{(f)}}) \longrightarrow H^1(N_{C_D^{(f)}|C^{(g-1)}}) \longrightarrow 0 \]

and the image of \( H^1(T_{C^{(g-1)}}|_{C_D^{(f)}}) \) in \( H^1(T_A|_{C_D^{(f)}}) \) is the span of the images of \( H^1(T_C) = H^1(T_{C^{(f)}}) \) and \( \bigoplus_{i=1}^{g-1-f} S^i H^0(t_i) \otimes H^1(\mathcal{O}_C) \).

The image of \( \bigoplus_{i=1}^{g-1-f} S^i H^0(t_i) \) in \( H^0(T_A) = H^1(\mathcal{O}_C) \) is \( V(D) \). Indeed, as we saw above, \( H^0(T_{C^{(g-1)}}|_{C_D^{(f)}}) \cong H^0(N_{C_D^{(f)}|C^{(g-1)}}) = \bigoplus_{i=1}^{g-1-f} S^i H^0(t_i) \) has dimension \( g - 1 - f \). The tangent space to \( C^{(g-1)} \) at \( D_{g-1} \in C^{(g-1)} \) can canonically be identified with \( \mathcal{O}_{D_{g-1}}(D_{g-1}) \). For all \( D_{g-1} \in C_D^{(f)} \subset C^{(g-1)} \), we have \( \mathcal{O}_D(D) \subset \mathcal{O}_{D_{g-1}}(D_{g-1}) \). So \( \mathcal{O}_D(D) \subset H^0(T_{C^{(g-1)}}|_{C_D^{(f)}}) \) and the two spaces are equal since they have the same dimension. The image of \( \mathcal{O}_D(D) \) in \( H^0(T_A) = H^1(\mathcal{O}_C) \) by the differential of the map \( \rho : C^{(g-1)} \to A \) is \( V(D) \). So the image of \( H^0(T_{C^{(g-1)}}|_{C_D^{(f)}}) \) in \( H^1(\mathcal{O}_C) \)
is $V(D)$. Therefore the image of $H^0(T_{C^{(g-1)}}|_{C^{(f)}_D}) \otimes H^1(O_C) = \oplus_{i=1}^{g-1} S^{f-1} H^0(t_i) \otimes H^1(O_C)$ in $H^1(T_{A|_{C^{(f)}_D}}) = H^1(O_C) \otimes \mathbb{C}$ is $V(D) \otimes H^1(O_C)$. \hfill \Box

Therefore, if $Z_{g-1 \cap C^{(f)}_D}$ has codimension 2 in $C^{(f)}_D$, then the kernel of $S^2 H^1(O_C) \rightarrow H^0(O_{Z_{g-1 \cap C^{(f)}_D}})$ is the span of $H^1(T_C)$ and $S^2 V(D)$.

Since we have assumed $h^0(D) = 1$, the codimension of $Z_{g-1 \cap C^{(f)}_D}$ is at least 1. If the codimension of $Z_{g-1 \cap C^{(f)}_D}$ in $C^{(f)}$ is 1, then we have the exact sequence

$$0 \rightarrow K_Y \rightarrow \mathcal{I}_{Z_{g-1}}(\theta)|_{C^{(f)}} \rightarrow \mathcal{I}_{Z_{g-1 \cap C^{(f)}}}(\theta) \rightarrow 0$$

where $Y$ is the maximal subscheme of $Z_{g-1 \cap C^{(f)}_D}$ supported on the union of its codimension 1 components and $K_Y$ is the sheaf on $Y$ defined by the exact sequence. If $f = 1$, then $Y$ has dimension 0, $h^1(K_Y) = 0$, $H^1(\mathcal{I}_{Z_{g-1}}(\theta)|_{C^{(f)}}) = H^1(\mathcal{I}_{Z_{g-1 \cap C^{(f)}}}(\theta))$ and the kernel of

$$S^2 H^1(O_C) \rightarrow H^0(O_{Z_{g-1}}(\theta)) \rightarrow H^0(O_{Z_{g-1 \cap C^{(f)}}}(\theta)) \rightarrow H^1(\mathcal{I}_{Z_{g-1 \cap C^{(f)}}}(\theta))$$

is again the intersection of the image of $H^1(T_{C^{(g-1)}}|_{C^{(f)}_D})$ with $S^2 H^1(O_C)$.

Suppose from now on that $2 \leq f \leq g - 1$. We have

**Lemma 5.2.** The codimension of $Z_{g-1 \cap C^{(f)}_D}$ is 1 only in the following cases

1. The intersection $Z_{g-1 \cap C^{(f)}_D}$ contains $C^{(f-1)}_t$ for some $t \in C$. This happens if and only if $\langle D \rangle \cap C$ contains $D + t$.

2. The restriction to $C$ of the projection from $\langle D \rangle$ is not birational to its image. Letting $C'$ be the normalization of this image, the projection from $\langle D \rangle$ induces $\kappa : C \rightarrow C'$ of degree at least 2. Given $\kappa$, there exist a finite number of linear subspaces $L_i$ ($i = 1, \ldots, l$) of $|\omega_C|^*$ such that any such $\langle D \rangle$ contains $L_i$ for some $i$. Furthermore, $Z_{g-1 \cap C^{(f)}_D}$ contains the divisor $C^{(f-2)} + X(\kappa) \subset C^{(f)}$ where

$$X(\kappa) := \{ D_2 \in C^{(2)} : \exists t \in C', h^0(\kappa^*(t) - D_2) > 0 \}.$$

**Proof.** The first case is clear. Assume therefore that $Z_{g-1 \cap C^{(f)}_D}$ contains an irreducible divisor $\mathcal{F}$ which is not of the form $C^{(f-1)}_t$. It is easily seen that this is equivalent to the fact that for a general divisor $D_{f-2} \in C^{(f-2)}$, the projection from $\langle D + D_{f-2} \rangle$ is not birational on $C$. It first follows that the projection from $\langle D \rangle$ is not birational on $C$. Indeed, if we call $C_1$ the image of $C$ by the projection from $\langle D \rangle$, then, by the general position theorem (\cite{2} page 109), the projection of $C_1$ from the span of a general effective divisor on it is always birational unless the image of
the projection is $\mathbb{P}^1$ or a point. So, if the projection of $C$ from $\langle D \rangle$ is birational, then so is its projection from $\langle D + D_f - 2 \rangle$ for $D_f - 2 \in C_{(f-2)}$ general.

The general divisors $D_f \in \mathcal{F}$ are of the form $D_{f-2} + D_2$ where $D_{f-2} \in C_{(f-2)}$ is general and $D_2 \leq \kappa^*(t)$ for some $t \in C'$, i.e.,

$$\mathcal{F} = C_{(f-2)} + X(\kappa).$$

To prove the assertion about the $L_i$, first suppose that the cover $\kappa : C \to C'$ is Galois and let $\{\sigma_1, \ldots, \sigma_n\}$ be a set of generators for its Galois group. Then, since the projection from $\langle D \rangle$ induces $\kappa$, the linear space $\langle D \rangle$ is globally invariant under $\sigma_1, \ldots, \sigma_n$ and $\sigma_1, \ldots, \sigma_n$ induce the identity on $|\omega_C|^*/\langle D \rangle$. Therefore, if we let $V$ be the vector space whose projectivization is $|\omega_C|^*/\langle D \rangle$, then, for all $i$, $\sigma_i$ has only one eigenvalue, say $\lambda_i$ on $V$. Hence $\langle D \rangle$ contains the eigenspaces of $\sigma_i$ for all its eigenvalues which are distinct from $\lambda_i$. For each choice $\mu_1, \ldots, \mu_n$ of eigenvalues of $\sigma_1, \ldots, \sigma_n$, we let $L(\mu_1, \ldots, \mu_n)$ be the smallest linear subspace of $|\omega_C|^*$ which, for all $i$, contains all the eigenspaces of $\sigma_i$ distinct from $\mu_i$. Assuming none of the $\sigma_i$ is the identity on $C$, all the $L(\mu_1, \ldots, \mu_n)$ are non-empty. So we see that $L(\lambda_1, \ldots, \lambda_n) \subset \langle D \rangle$. It is immediate that a linear subspace $L$ contains some $L(\mu_1, \ldots, \mu_n)$ if and only if the projection from $L$ factors through $\kappa : C \to C'$. Therefore, the $L(\mu_1, \ldots, \mu_n)$ are the minimal subspaces $L$ of $|\omega_C|^*$ such that the projection from $L$ factors through $\kappa : C \to C'$. This description shows that they only depend on $\kappa$ and not the choice of the generating set $\{\sigma_1, \ldots, \sigma_n\}$. We number them to obtain the subspaces $L_i$ ($i = 1, \ldots, l$) in the statement.

Now, if the cover $\kappa : C \to C'$ is not Galois, it can be dominated by a Galois cover: in other words, there exists a Galois cover $\tilde{\kappa} : \tilde{C} \to C'$ which factors through $\kappa : C \to C'$. The induced map on the jacobians $J\tilde{C} \to JC$ induces a projection $|\omega_{\tilde{C}}|^* \to |\omega_C|^*$ which, composed with the map $|\omega_C|^* \to |\omega_C|^*/\langle D \rangle$, induces $\tilde{\kappa}$. The subspaces $L_i$ are well-defined for $\tilde{\kappa}$ and their images in $|\omega_C|^*$ will give us the subspaces $L_i$ for $\kappa$. \hfill \square

**Lemma 5.3.** Suppose $e \leq g - 3$. For $D \in X$ general, the intersection $Z_{g-1} \cap C_{D}^{(g-1-e)}$ has codimension 2 in $C_{D}^{(g-1-e)}$.

**Proof.** We have to prove that neither of the two cases in Lemma 5.2 occur.

If, for $D$ general in $X$, $\langle D \rangle$ contains one of the linear spaces $L_i$ from Lemma 5.2, then, since $X$ is irreducible, for all $D \in X$, $\langle D \rangle \supset L_i$. Choose now $D_{e+1}$ general in $X_{e+1}(L)$. Then, by Lemma 5.1, $h^0(D_{e+1}) = 1$ so that $\cap_{D \leq D_{e+1}} \langle D \rangle = \emptyset$ and it cannot contain any $L_i$. 

Suppose now that, for $D$ general in $X$, $\langle D \rangle \cap C \supset D + t_D$ for some $t_D \in C$. Then if we choose $D_{e+1}$ as above and $D \leq D_{e+1}$ again, we see that $D + t_D \subset \langle D_{e+1} \rangle$. If the $t_D$ are distinct for the distinct subdivisors of $D_{e+1}$, then we obtain a contradiction by Clifford’s Theorem and the fact that $C$ is not hyperelliptic. Since any two subdivisors of degree $e$ of $D_{e+1}$ have $e - 1$ points in common, we see then that there is a divisor $D_{e-1} \in X_{e-1}(L)$ such that $\langle D_{e-1} \rangle \cap C \supset D_{e-1} + t$ for some $t \in C$. Since $X_{e-1}(L)$ is also irreducible and our choices of divisors were general, this is the case for all $D_{e-1} \in X_{e-1}(L)$. Repeating the argument with $e - 1$ instead of $e$ and continuing, we arrive at a contradiction. □

5.3. Therefore, by what we saw above, for $D \in X$ general, the kernel of $S^2H^1(\mathcal{O}_C) \to H^0(\mathcal{O}_{Z_{g-1}\cap C(D)})$ is the span of $H^1(T_C)$ and $S^2V(D)$. We have

**Lemma 5.4.** Assume $e \leq g - 3$ and

1. either $d \geq 2e + 2$,
2. or $d = 2e + 1$, $h^0(L) \leq e$,
3. or $d = 2e$, $h^0(L) \leq e - 1$.

Then there is a reduced $D \in X_{e+1}(L)$ such that $h^0(D) = 1$ and $\langle D \rangle \cap C = D$.

**Proof.** By Lemma 5.2 there is $E \in X_{e+2}(L)$ such that $h^0(E) = 1$ and $E$ is reduced. We claim that there is $D \leq E$ with $\langle D \rangle \cap C = D$. Suppose not so that the span of every subdivider of degree $e + 1$ of $E$ contains an extra point of $C$. If two of these points are equal, then we have a subdivider of degree $e$ of $E$ whose span contains an extra point of $C$ and this is not possible for all such $E$ by the previous two Lemmas. So the span of $E$ contains $e + 2$ distinct extra points which is the number of subdivisors of degree $e + 1$ of $E$. Therefore we have a divisor $E'$ of degree $e + 2$ such that $\langle E + E' \rangle$ has dimension $e + 1$. Hence $h^0(E + E') = 1 + e + 2 = e + 3$. By Clifford’s Theorem, since $C$ is not hyperelliptic, this is possible only if $E + E'$ is a canonical divisor on $C$. In particular, $e = g - 3$.

Put $E = t_1 + \ldots t_{g-1}$ and $E' = s_1 + \ldots + s_{g-1}$, the points being numbered in such a way that for all $j$, $s_j + \sum_{i \neq j} t_i \leq \langle \sum_{i \neq j} t_i \rangle \cap C$, i.e., $h^0(s_j + \sum_{i \neq j} t_i) = 2$. Since $E + E'$ is a canonical divisor, we also have $h^0(t_j + \sum_{i \neq j} s_i) = 2$ for all $j$, i.e., $t_j + \sum_{i \neq j} s_i \leq \langle \sum_{i \neq j} s_i \rangle \cap C$. Choose a basis of $V(E) = V(E + E') \subset H^1(\mathcal{O}_C)$ in which the coordinates of $t_j$ are $(0, \ldots 0, 1, 0, \ldots 0)$ where $1$ is in the $j$-th slot. Let $(a_{j1}, \ldots, a_{j g-1})$ be the coordinates of $s_j$. Then $a_{jj} = 0$ for all $j$. Take $j = 1$.
Then $a_{11} = 0$ and the condition $t_1 \in \langle \sum_{i=2}^{g-1} s_i \rangle$ means there are scalars $\lambda_2, \ldots, \lambda_{g-1}$ such that
\[
1 = \sum_{i=2}^{g-1} \lambda_i a_{i1}\\
0 = \sum_{i=2}^{g-1} \lambda_i a_{ik} \text{ for all } k \geq 2
\]
Since $E + E'$ is a canonical divisor and $h^0(E) = 1$, we also have $h^0(E') = 1$. Therefore the $s_j$ are linearly independant and, a fortiori, the minor $|a_{jk}|_{2 \leq j \leq g-1}$ is not zero and the condition $0 = \sum_{i=2}^{g-1} \lambda_i a_{ik}$ for all $k \geq 2$ implies $\lambda_i = 0$ for all $i$. Then the condition $1 = \sum_{i=2}^{g-1} \lambda_i a_{i1}$ gives a contradiction. \qed

**Lemma 5.5.** Suppose $1 \leq e \leq g - 3$ and $D := t_1 + \ldots + t_{e+1}$ is a reduced divisor such that $h^0(D) = 1$ and $\langle D \rangle \cap C = D$. Put $E_i := D - t_i$. Then
\[
\bigcap_{i=1}^{e+1} \langle H^1(T_C), S^2 V(E_i) \rangle = H^1(T_C).
\]

**Proof.** We proceed by induction on $e$. For $e = 1$, we have $E_i = t_{2-i}$,
\[
S^2 V(E_i) \subset H^1(T_C),
\]
and the result is trivially true. Suppose $e \geq 2$ and the result holds for $e - 1$. Let us rewrite
\[
\bigcap_{i=1}^{e+1} \langle H^1(T_C), S^2 V(E_i) \rangle = \bigcap_{i=1}^e \left( \langle H^1(T_C), S^2 V(E_i) \rangle \cap \langle H^1(T_C), S^2 V(E_{e+1}) \rangle \right).
\]

We will prove that
\[
\langle H^1(T_C), S^2 V(E_i) \rangle \cap \langle H^1(T_C), S^2 V(E_{e+1}) \rangle = \langle H^1(T_C), S^2 V(E'_i) \rangle
\]
where $E'_i := D - t_i - t_{e+1} = E_{e+1} - t_i$. Then replacing $D$ with $E_{e+1}$ we are reduced to the statement for $e - 1$.

Dually, we will prove that the annihilators in $S^2 H^0(\omega_C)$ of the two spaces are equal. The annihilator of $H^1(T_C)$ is $I_2(C)$. That of $\langle H^1(T_C), S^2 V(E) \rangle$ for any divisor $E$ is the space $I_2(C, E)$ of homogeneous degree 2 forms vanishing on $C$ and the linear span $\langle E \rangle$ of $E$ in $|\omega_C|^*$. The statement we need to prove has now become
\[
I_2(C, D - t_i - t_{e+1}) = I_2(C, D - t_i) + I_2(C, D - t_{e+1}).
\]
Choose $g - 3 - e$ general points $t_{e+2}, \ldots, t_{g-2}$ on $C$. Then
\[
\langle \sum_{i=1}^{g-2} t_i \rangle \cap C = \sum_{i=1}^{g-2} t_i
\]
and the $t_i$ are linearly independent and distinct. In particular, the $t_i$ impose independent conditions on quadrics.

We claim that the restriction map

$$I_2(C) \longrightarrow S^2V(\sum_{i=1}^{g-2} t_i)^*$$

induces an isomorphism between $I_2(C)$ and the homogeneous degree 2 forms on $V(\sum_{i=1}^{g-2} t_i)$ vanishing at the points $t_i$. These two spaces have the same dimension so it is sufficient to prove that the restriction map is injective, i.e., no quadric in $|\omega_C|^*$ containing the canonical curve $C$ contains $\langle \sum_{i=1}^{g-2} t_i \rangle$. Since $\langle \sum_{i=1}^{g-2} t_i \rangle$ has codimension 2, if a quadric contains it, then the quadric has rank $\leq 4$. Then $\langle \sum_{i=1}^{g-2} t_i \rangle$ is a member of a ruling of the quadric and by \[1\] cuts a divisor of a $g^1_d$ on $C$.

This, however, is not possible by our assumptions on the $t_i$.

It first follows from this that

$$\dim I_2(C, D - t_{e+1}) = \dim I_2(C, D - t_i) = \dim I_2(C) - \binom{e}{2} = \binom{g-2}{2} - \binom{e}{2}$$

$$\dim I_2(C, D - t_{e+1} - t_i) = \dim I_2(C) - \binom{e - 1}{2} = \binom{g-2}{2} - \binom{e - 1}{2}.$$ 

So to prove our claim we need to prove that

$$\dim (I_2(C, D - t_{e+1}) \cap I_2(C, D - t_i)) = 2 \left( \binom{g-2}{2} - \binom{e}{2} \right) - \left( \binom{g-2}{2} - \binom{e-1}{2} \right) = \binom{g-2}{2} - \binom{e}{2} - (e-1)$$

This is easily seen to be true from our assumptions on the $t_i$. □

5.4. So far it follows from our results above that the intersection of the kernels of the maps

$$S^2H^1(O_C) \longrightarrow H^0(O_{Z_{g-1}}(\Theta)) \longrightarrow H^0(O_{Z_{g-1} \cap C^{(g-1-e)}_E}(\Theta))$$

as $E$ varies in $X$ is $H^1(T_C)$. Therefore (see \[5.1\] for a given $\eta \notin H^1(T_C)$, there exists $a = \sum p_i - \sum q_i$ such that $\eta$ is not in the kernel of the map

$$S^2H^1(O_C) \longrightarrow H^0(O_{Z_{g-1}}(\Theta)) \longrightarrow H^0(O_{Z_{g-1} \cap X_{-a}}(\Theta)).$$
6. The kernel of the map $H^0(\mathcal{O}_{Z_{g-1\cap X_a}}(\Theta)) \to H^1(\mathcal{I}_{Z_{g-1\cap X_a}}(\Theta))$

We continue with the analysis of the kernel of the coboundary map

$$H^0(\mathcal{O}_{Z_{g-1\cap X_a}}(\Theta)) \to H^1(\mathcal{I}_{Z_{g-1\cap X_a}}(\Theta))$$

and see that in fact we can choose our $a$ above also in such a way that this map is injective.

6.1. Let $\tilde{Z}(X) \subset C^{(g-1-e)} \times X$ be the closure of the subvariety parametrizing pairs $(\sum q_i, D_e)$ such that $h^0(\sum q_i) = h^0(D_e) = 1$ and $h^0(\sum q_i + D_e) \geq 2$. Let $Z(X) \subset C^{(g-1-e)}$ be the image of $\tilde{Z}(X)$ by the first projection.

**Lemma 6.1.** The varieties $\tilde{Z}(X)$ and $Z(X)$ are not empty.

**Proof.** Choose a general $D_e \in X$ so that we have $h^0(D_e) = 1$ (see Lemma 1.1 or 5.4). If, for all $\sum q_i \in C^{(g-1-e)}$ with $h^0(\sum q_i + D_e) \geq 2$, we have $h^0(\sum q_i) \geq 2$, then, for some $r \geq 1$, the dimension of $W^r_{g-1-e}$ is at least $g - 1 - e - r - 2 = g - e - r - 3$. By [12] pp. 348-350, this can only be the case if $r = 1$ and either $C$ is trigonal, bielliptic or a smooth plane quintic.

In the trigonal case $W^1_{g-1-e} = g_3 + C^{(g-e-4)}$. For a point $t$ of $D_e$, the divisor $\sum q_i = g_3^1 - t + D_{g-3-e}$ with $D_{g-3-e} \in C^{(g-1-3)}$ general satisfies $h^0(\sum q_i) = 1$ and $h^0(\sum q_i + D_e) \geq 2$.

In the bielliptic case, if $\pi : C \to E$ is the bielliptic cover, then $W^1_{g-1-e} = \pi^* W^1_2(E) + C^{(g-e-5)}$. For two distinct points $s$ and $t$ of $D_e$, the divisor $\iota s + \iota t + D_{g-3-e}$ with $D_{g-3-e} \in C^{(g-1-3)}$ general and $\iota$ the bielliptic involution satisfies $h^0(\sum q_i) = 1$ and $h^0(\sum q_i + D_e) \geq 2$.

In the case of the smooth plane quintic, we have $g - 1 - e = 4 = g - 2$. So $e = 1$ which is excluded. \[\square\]

**Lemma 6.2.** Suppose that for $\sum q_i \in Z(X)$ with $h^0(\sum q_i) = 1$ the coboundary map

$$H^0(\mathcal{O}_{Z_{g-1\cap X}}(\Theta_a)) \to H^1(\mathcal{I}_{Z_{g-1\cap X}}(\Theta_a))$$

is not injective, then

$$H^0(K - \sum q_i - L) \neq 0.$$ 

**Proof.** Using the exact sequence

$$0 \to H^0(\mathcal{I}_{Z_{g-1\cap X}}(\Theta_a)) \to H^0(\mathcal{O}_X(\Theta_a)) \to H^0(\mathcal{O}_{Z_{g-1\cap X}}(\Theta_a)) \to H^1(\mathcal{I}_{Z_{g-1\cap X}}(\Theta_a)),$$
we need to understand the sections of $\mathcal{O}_X(\Theta_a)$ which vanish on $Z_{g-1} \cap X$. For this, we use the embedding of $X$ in $C^{(e)}$:

$$0 \to \mathcal{I}_{X/C^{(e)}}(\Theta_a) \to \mathcal{O}_{C^{(e)}}(\Theta_a) \to \mathcal{O}_X(\Theta_a) \to 0.$$ 

By Appendix 6.1 in [5] this gives the exact sequence of cohomology

$$0 \to H^0(\mathcal{I}_{X/C^{(e)}}(\Theta_a)) \to \wedge^e H^0(C, K - \sum_{i=1}^{g-e-1} q_i) \to H^0(X, \Theta_a) \to H^1(\mathcal{I}_{X/C^{(e)}}(\Theta_a)).$$

By Appendix 6.2 in [5] the elements of $H^0(C^{(e)}, \Theta_a) = \wedge^e H^0(C, K - \sum_{i=1}^{g-e-1} q_i)$ all vanish on $Z_{g-1} \cap C^{(e)}$, hence they also vanish on $Z_{g-1} \cap X$. So if the coboundary map is not injective, then there must be elements of $H^0(X, \Theta_a)$ which are not restrictions of elements of $H^0(C^{(e)}, \Theta_a)$.

In particular, we must have $H^1(\mathcal{I}_{X/C^{(e)}}(\Theta_a)) \neq 0$. By sequence (1.2), this implies that there is an integer $j \in \{1, \ldots, e\}$ such that $H^{j-1}(\Lambda^j V^e(L)(\Theta_a)) \neq 0$. Equivalently, $H^{e-j+1}(\omega_{C^{(e)}}(-\Theta_a) \otimes \Lambda^j V^e_L) \neq 0$. By Appendix 6.1 since (5) Appendix

$$\pi^*_e \mathcal{O}_{C^{(e)}}(\Theta_a) \cong p_1^* \mathcal{O}_C(K - q) \otimes \cdots \otimes p_e^* \mathcal{O}_C(K - q)(-\sum_{1 \leq k \leq l \leq e} \Delta_{k,l}),$$

this implies that

$$H^{e-j+1}(p_1^* \mathcal{O}_C(L + q) \otimes \cdots \otimes p_j^* \mathcal{O}_C(L + q) \otimes p_{j+1}^* \mathcal{O}_C(q) \otimes \cdots \otimes p_e^* \mathcal{O}_C(q)(-\sum_{1 \leq k \leq l \leq j} \Delta_{k,l}))^{\mathfrak{S}_j \times \mathfrak{S}_{e-j}} \neq 0$$

As in the Appendix of [5] the above cohomology group is equal to the group of elements of

$$H^{e-j+1}(p_1^* \mathcal{O}_C(L + q) \otimes \cdots \otimes p_j^* \mathcal{O}_C(L + q) \otimes p_{j+1}^* \mathcal{O}_C(q) \otimes \cdots \otimes p_e^* \mathcal{O}_C(q))$$

anti-invariant under the action of $\mathfrak{S}_j$ and invariant under the action of $\mathfrak{S}_{e-j}$. Therefore its non-vanishing implies the non-vanishing of $H^1(L + q) = H^1(L + \sum q_i) = H^0(K - \sum q_i - L)^*$. \qed

6.2. By Lemma 6.1 the variety $\tilde{Z}(X)$ is not empty. Therefore $\tilde{Z}(X)$ has dimension at least $g - e - 2$. By Lemma 6.3 below this implies that $Z(X)$ also has dimension $\geq g - e - 2$. Therefore the hypothesis and hence the conclusion of Lemma 6.2 hold for a $(g - e - 2)$-dimensional family of $\sum_{i=1}^{g-e-1} q_i$. This implies $h^0(K - L) \geq g - e - 1$. Therefore, by Clifford’s Lemma, since $C$ is not hyperelliptic, we have $2(g - e - 1) < 2g - 2 - d$ or $d \leq 2e + 1$. If $d = 2e + 1$, then $h^0(L) = e + 1$ and $C$ has Clifford index 1 if $e \leq g - 3$.

Lemma 6.3. The projection $\tilde{Z}(X) \to Z(X)$ is generically finite.
Proof. If not, then some component of $\tilde{Z}(X)$ maps with one-dimensional fibers into $Z(X)$. Since $X$ is integral, these one-dimensional fibers are all isomorphic to $X$. Hence there is a $(g - e - 3)$-dimensional family of divisors $q = \sum q_i$ such that $h^0(q) = 1$ and, for every $D_e \in X$, $h^0(q + D_e) \geq 2$.

Let $e'$ be the largest integer such that for a general such $q$ and a general $D_{e'} \in X_{e'}(L)$, we have $h^0(q + D_{e'}) = 1$. It is immediate that $1 \leq e' \leq e - 1$. For a fixed general such $D_{e'}$, let $D$ be the divisor of $L$ containing $D_{e'}$ and let $t$ be a point of $D - D_{e'}$. Then $h^0(q + D_{e'} + t) = 2$. Equivalently $h^0(K - q - D_{e'} - t) = h^0(K - q - D_{e'})$, i.e., $t$ is a base point of the linear system $|K - q - D_{e'}|$. Since $D_{e'}$ is general, so is $D$, hence $D$ is reduced and, furthermore, it has no points in common with $q$. It follows that all of $D - D_{e'}$ is contained in the base locus of $|K - q - D_{e'}|$. By Riemann-Roch and Serre duality we see that this implies $h^0(q + D) = 1 + d - e'$. So $C$ has a family of dimension $g - e - 3$ of linear systems of degree $g - 1 - e + d$ and dimension $d - e'$. Since $C$ is not hyperelliptic, it follows from [12] pp. 348-350 that $g - e - 3 \leq g - 1 - e + d - 2(d - e') - 1$, i.e., $d \leq 2e' + 1 \leq 2e - 1$ which contradicts the hypothesis $d \geq 2e$. \hfill $\square$

7. The Consequences of Theorem 0.1

If $C$ has a $g_{2e}^{e-1}$ (resp. $g_{2e+1}^e$), then $C$ has Clifford index 2 (resp. 1). By a result of Martens ([10] Satz 4 page 80), if $C$ is non-bielliptic, has Clifford index 2 (resp. 1) and genus at least 10 (resp. 8), then $C$ has no $g_{2e}^{e-1}$ for $4 \leq e \leq g - 5$ (resp. no $g_{2e+1}^e$ for $3 \leq e \leq g - 5$). The cases of low genus are easily analyzed [6] and we see that the cases in which $X$ might deform with $JC$ out of the jacobian locus are

(1) $C$ any curve, $e = g - 2$,

(2) $C$ with a $g_1^2$ and hence also a $g_{2g-4}^{g-4} = |K_C - g_1^1|$, $e = 2$ or $g - 3$,

(3) $C$ with a $g_6^2$, $e = 3$ or $g - 4$,

(4) $C$ with a $g_3^1$, $e = g - 4$ or $g - 3$,

(5) $C$ with a $g_8^2$, $e = 2$ or $g - 4$,

(6) $C$ bielliptic, $2 \leq e \leq g - 2$.

8. Appendix

8.1. The cohomology of $I_{X/C} \otimes N$. Here we introduce a method for computing the cohomology of $I_{X/C} \otimes N$ where $N$ is a locally free sheaf on $C^{(e)}$. One way to approach this calculation is to compute the cohomologies of the pieces $\Lambda^j V_L^{\alpha} \otimes S^j W(L) \otimes N$ of the resolution [12] of
\[ V^e_L = q_{e*}(p_e^*\mathcal{O}(L)|_{D^e}) \]

where \( D^e \subset C^{(e)} \times C \) is the universal divisor and \( q_e, p_e \) are the first and second projections of \( C^{(e)} \times C \) onto its two factors. On this model, for \( 1 \leq j \leq e \), let

\[ Y^{e,j} \subset C^{(e)} \times C^{(j)} \]

be the universal subvariety, i.e.,

\[ Y^{e,j} := \{(D_e, D_j) \in C^{(e)} \times C^{(j)} : D_e \geq D_j\} \]

and let \( q_{e,j} \) and \( p_{e,j} \) be the first and second projections of \( C^{(e)} \times C^{(j)} \) onto its two factors. Then a moment of reflection will convince the reader that

\[ \Lambda^j V^e_L = q_{e,j*}( (p_{e,j}^*\mathcal{L}'_{L,j}) |_{Y^{e,j}} ) \]

where, as in [5], \( \mathcal{L}'_{L,j} \) is the sheaf on \( C^{(j)} \) whose inverse image on \( C^j \) is \( p_j^*\mathcal{O}(L) \otimes \ldots \otimes p_j^*\mathcal{O}(L) \left( - \sum_{1 \leq k < l \leq j} \Delta_{k,l} \right) \). So

\[ H^k(\omega_{C^{(e)}} \otimes N^* \otimes \Lambda^j V^e_L) = H^k(\omega_{C^{(e)}} \otimes N^* \otimes q_{e,j*}( (p_{e,j}^*\mathcal{L}'_{L,j}) |_{Y^{e,j}} )) \]

is a graded piece of the filtration of

\[ H^k(q_{e,j*}^* (\omega_{C^{(e)}} \otimes N^*) \otimes p_{e,j}^*\mathcal{L}'_{L,j}|_{Y^{e,j}}) \]

induced by the Leray Spectral sequence of the fibration \( q_{e,j} : C^{(e)} \times C^{(j)} \to C^{(e)} \). The morphism

\[
\begin{align*}
C^e & \quad \longrightarrow \quad Y^{e,j} \\
(s_1, \ldots, s_e) & \quad \longmapsto \quad (s_1 + \ldots + s_e, s_1 + \ldots + s_j)
\end{align*}
\]

shows that \( Y^{e,j} \) is the quotient of \( C^e \) by the action of \( S_j \times S_{e-j} \) which permutes the first \( j \) points and the last \( e - j \) points. Therefore

\[
H^k(q_{e,j*}^* (\omega_{C^{(e)}} \otimes N^*) \otimes p_{e,j}^*\mathcal{L}'_{L,j}|_{Y^{e,j}}) = H^k(\pi_{e,j*}^* (\omega_{C^{(e)}} \otimes N^*) \otimes p_{e,j}^*\mathcal{L}'_{L,j}|_{Y^{e,j}}) \otimes_{S_j} \otimes_{S_{e-j}}
\]

\[
= H^k(p_1^*\mathcal{O}(K + L) \otimes \ldots \otimes p_j^*\mathcal{O}(K + L) \otimes p_{j+1}^*\mathcal{O}(K) \otimes \ldots \otimes p_e^*\mathcal{O}(K) \otimes \pi_e^*N^*
\]

\[
(- \sum_{1 \leq k < l \leq j} \Delta_{k,l} - \sum_{1 \leq k < l \leq e} \Delta_{k,l})) \otimes_{S_j} \otimes_{S_{e-j}}.
\]
8.2. The purpose of this section is to show that when \( e \leq g - 3 \), for a sufficiently general pair \((C, L)\) the curve \( X \) obtained satisfies the condition

\[
X \cap Z_{g-1} = X \cap Z_q
\]

for all \( \sum q_i \in C^{(g-1-e)} \). Since the schemes \( Z_{g-1} \cap (W_e - a) \) and \( Z_q \) are equal outside \( Z_e \), this will follow if we show that \( X \cap Z_e = \emptyset \).

So we shall prove that for \((C, L)\) sufficiently general, there is no subdivisor \( D \) of degree \( e \) of a divisor of \( L \) such that \( h^0(D) \geq 2 \). If \( d \leq g + 1 \), then for a sufficiently general \((C, L)\), \( h^0(L) = 2 \) and since we can suppose \( L \) base-point-free, the assertion is true.

Suppose therefore that \( d \geq g + 2 \). In such a case, supposing \((C, L)\) general also means that \( C \) is general, since a general curve has \( g^1_3 \)'s. If \( e < \frac{2+2}{2} \), then by Brill-Noether theory a general curve does not have any \( g^1_3 \) and the assertion is true.

So we suppose \( e \geq \frac{2+2}{2} \) (which then implies \( d \geq g + 2 \)). In this case we prove that in a general linear system \( G \) of degree \( d \geq g + 2 \) on the general curve \( C \), the family \( M_G \) of divisors of the form \( D_e + D_{d-e} \) with \( h^0(D_e) \geq 2 \) has codimension at least 2. Then a general pencil \( L \) in \( G \) will not intersect \( M_G \). It suffices to show that the union \( M := \bigcup_{deg(G)=d} M_G \) has dimension at most \( d - 2 \) since \( \bigcup_{deg(G)=d} G = C^{(d)} \) has dimension \( d \). We can rewrite \( M = C_1^{(e)} + C^{(d-e)} := \bigcup_{D \in C_1^{(e)} \subset C^{(d-e)}} \).

Since \( C \) is general, by Brill-Noether theory

\[
\dim W_e^1 = g - 2(g - e + 1) = 2e - g - 2.
\]

Hence \( \dim C_1^{(e)} = 2e - g - 1 \) and \( \dim M = 2e - g - 1 + d - e = d + e - g - 1 \). We have \( e - g - 1 \leq -2 \) which concludes our proof.
