Abstract

We review the theory that predicts that the decay constant of the excited light pseudo-scalar mesons are suppressed in the chiral limit relative to the pion decay constant. We compute the decay constant of the first excited pion ($\pi'$) using unquenched QCD at a fixed lattice spacing with sea quarks of mass as low as a third the mass of the strange quark. The final result is very sensitive to the improvement conditions. We obtain $f_{\pi'}/f_\pi = 0.078(93)$ in the chiral limit.

1 Introduction

Holl et al. have argued from Schwinger-Dyson equations and on general grounds that the decay constants of the excited light $0^{-+}$ mesons should be suppressed relative to the pion decay constant. The decay constant of the first excited pion has also been found to be small in \cite{2345678}. In table we summarise the values for the decay constant of the first excited pion from various models. The predictions from these models for $f_{\pi'}$ are indeed remarkably small. When we first heard about the result that the decay constant of the excited light pseudo-scalar could be as small a tenth of the pion decay constant, our first reaction was a combination of "that is remarkable" and "unbelievable". In this letter we check these predictions using lattice QCD.

Experimentally, the second lightest meson with $0^{-+}$ quantum numbers, made out of light quarks, is the $\pi(1300)$. In our lattice calculation we use the notation $\pi'$ for the first excited light pseudo-scalar meson.

From a (naive) quark model perspective it is surprising for the $\pi'$ to have a highly suppressed decay constant. We define highly suppressed to be that the decay constant is less than 10% of the pion decay constant. In the naive quark model the leptonic decay constant for S-wave states is proportional to
the wave-function at the origin. The wave function of the excited $0^{-+}$ state would be smaller than the ground state, because the wave-function is more spread out than for the ground state. However, there is no obvious reason for a dramatic suppression of the decay constant. It is instructive to consider the decay constants of mesons with heavy quarks. Lakhina and Swanson [10] have recently computed the leptonic decay constant of mesons in the charmonium and bottomonium systems and compared their values against experiment and lattice gauge theory. For example, Lakhina and Swanson [10] get good agreement from their model and the experimental results for the leptonic decay constants of the $J/\psi$ ($411 \pm 7$ MeV) and $\psi'$ ($279 \pm 8$ MeV) mesons. The same decay constants have also been computed by Dudek et al. [11] from quenched lattice QCD. This type of modest suppression of the value for the decay constant of the excited meson relative to the decay constant of the ground state agrees with our (perhaps simple minded) intuition.

Below is "simplistic" theoretical argument for the suppression of the decay constant of excited light pseudo-scalars. Consider the axial current applied to the meson $X$ (here applied to mesons with $J^{PC} = 0^{-+}$).

The decay constant ($f_X$) of the state $X$ is defined by

$$\langle 0 \mid A_\mu \mid X \rangle = if_X p_\mu$$  \hspace{1cm} (1)

where $A_\mu$ is the axial current. The partial conservation of the axial current [25] is

$$\partial_\mu A_\mu = m_q \pi$$  \hspace{1cm} (2)

where $\pi$ is the interpolating operator for pion states (pseudo-scalar density) and $m_q$ is the quark mass. Equation (2) is an operator relation, hence is true between any states. This allows us to write:

$$f_X = \frac{1}{m_X^2} m_q \langle 0 \mid \pi \mid X \rangle$$  \hspace{1cm} (3)

For the lightest pseudo-scalar

$$m_X^2 \propto m_q$$  \hspace{1cm} (4)

so $f_\pi$ is non-zero in the chiral limit. For a meson that is not a Goldstone state, $m_X$ is non-zero in the chiral limit, hence $f_X$ will vanish in the chiral limit.

In the past, corrections to equation (2) from excited pion states [2, 12] have been considered for corrections to the Goldberger-Trieman relation. For example [2] introduced extended PCAC

$$\partial^\mu A_\mu = \sum_n m_{\pi_n}^2 f_{\pi_n} \pi_n$$  \hspace{1cm} (5)

where $\pi_n$ is the interpolating operator for the $n$-th excited light $0^{-+}$ meson.

The PDG [13] quotes the mass of the $\pi(1300)$ as $1300 \pm 100$ MeV with a decay width of between 200 to 600 MeV. The predominant decay mode is to $\pi\pi\pi$ (this includes $\rho\pi$). There is readable discussion about the experimental
| Group                     | $f_{\pi'}$ MeV |
|--------------------------|----------------|
| Volkov and Weiss        | 0.68           |
| Elias et al.            | 4.2 ± 2.4      |
| Maltman and Kambor      | 3.11 ± 0.65    |
| Andrianov et al.        | 0.52 – 2.26    |
| Kataev et al.           | 4.3            |

Table 1: Summary of the values of the $\pi'$ decay constant determined from models and sum rules. Our normalisation convention is $f_\pi = 131$ MeV.

issues with the $\pi(1300)$ state in [14]. Diehl and Hiller [8] estimate the leptonic decay constant of the $\pi(1300)$ to be less than 8.4 MeV from the experimental bounds on the decay of the $\tau$ to $\pi(1300) + \nu_\tau$ from CLEO [13, 15].

The mass of the $\pi(1300)$ meson has been studied before using lattice QCD. Some quenched studies show reasonable agreement with experiment [16, 17]. The $\pi(1300)$ decays via the strong interaction, so quenched calculations would not be expected to be so accurate for this state. Using the maximum entropy method the CP-PACS collaboration obtained the mass of the first excited pion to be $660(590)$ MeV in the continuum limit of quenched QCD [17]. The CP-PACS collaboration [17] also computed the leptonic decay constant for the first excited $\rho$ meson. The ratio of the leptonic decay constant of the excited to ground rho meson, obtained by CP-PACS [17] was 0.41. This is modest in accord with our quark model intuition. The unquenched lattice QCD calculation by the MILC collaboration, using improved staggered quarks, obtained the first excited pseudo-scalar to be at the mass $1362(41)(205)$ MeV [18].

2 The lattice QCD calculation

In [21] the UKQCD collaboration reported results for the pion decay constant from a two flavour unquenched calculation. The masses of the first excited light pseudo-scalar meson were reported but not the respective decay constants. The paper by UKQCD used a variational technique, where a matrix of correlators is fitted to a transfer matrix based model. This is one of the more reliable techniques to study excited states on the lattice. Variational and other lattice methods to extract properties of excited hadrons are reviewed in [22].

In this paper we report the decay constant of the first excited light pseudo-scalar meson. The calculation used two flavours of degenerate sea quarks. The non-perturbatively improved clover action was used for the quarks with the Wilson gauge action. The lattice volume was $16^3 \times 32$ and $\beta = 5.2$. The lattice spacing is roughly 0.1 fm. The data for the pion decay constant and the mass of the $\pi'$ state have already been published in [21, 23], so we do not repeat that here. Note that UKQCD also showed good agreement between the pion decay constant computed by UKQCD and the JLQCD collaborations [24].

One consequence of the suppression of the decay constants of the excited
pions would be that the correlators for $\gamma_0\gamma_5$ to $\gamma_5$ should show less excited contamination than for the $\gamma_5$ to $\gamma_5$ correlator. In figure 1 the effective mass plots for the two local correlators look very similar. Recall, that the flatter the effective mass plot, the less excited state contamination there is.

We use variational smearing to extract the required matrix elements. A 4 by 4 matrix of correlators was computed using as basis states: local operator, fuzzed operator combined with the gamma matrix combinations $\gamma_5$ and $\gamma_0\gamma_5$. Two mass states were included in the fits. The heaviest state included in the fit is likely to have more excited state contamination in it.

The lattice axial current requires both matching factors to convert to $\overline{MS}$ scheme, as well as improvement factors. We use the formulation of the ALPHA collaboration [25].

\[
(A_R)^a_\mu = Z_A(1 + b_A m_q)(A_I)^a_\mu
\]  
(6)

We use the non-perturbative renormalisation and improvement factors recently computed by the ALPHA collaboration [26, 27] for two flavour unquenched QCD. At $\beta = 5.2$ the ALPHA expressions give $c_A = -0.0641$ [26]. At present, the $b_A$ factor is only known to one loop in perturbation theory.

The $f_{\pi'}$ decay constant is extracted from the following combination.

\[
f_{\pi'} = Z_A(1 + b_A m)(a f_{\pi'} + c_A f_{\pi'})
\]  
(7)

where $f_{\pi'} = \frac{1}{m} \langle 0 | \bar{\psi}\gamma_0\gamma_5\psi | \pi' \rangle$ and $f_{\pi'} = \frac{1}{m} \langle 0 | \partial_4 \bar{\psi}\gamma_5\psi | \pi' \rangle$.

In figure 2 we plot the ratio of the ratio of the decay constants of the $\pi$ and $\pi'$ meson, using the unimproved and improved decay constants from the ALPHA formulation. On the x-axis we use the square of the pion mass in...
Table 2: Components of the π′ decay constant. The ground state decay constants are in the second table of [21]. The improved decay constant of the π′ state is given by equation 7.

| κ  | a f_{π'} | a f_{π'}' |
|----|----------|----------|
| 0.1358 | 0.042^{+6}_{-8} | 0.585^{+4}_{-7} |
| 0.1355 | 0.065^{+12}_{-8} | 0.60^{+6}_{-6} |
| 0.1350 | 0.11^{+1}_{-2} | 0.73^{+6}_{-9} |

Figure 2: Ratio of the decay constants of the first excited to ground state light pseudo-scalar meson as a function of the pion mass squared. The horizontal line is the experimental upper limit from Diehl and Hiller [8].

units of r_0. The value of r_0 is not needed for our final result, but a value of r_0 around 0.5 fm with 10% errors can be used if required [28]. The unimproved decay constant has only a modest suppression of f_{π'} relative to f_π. The value of f_{π'} obtained from the improved ALPHA formulation is very much suppressed relative to f_π. In the continuum limit the improved and un-improved decay constants should agree. However, at the fixed lattice spacing that we use here, the improved decay constant should be close to the continuum limit value of the decay constant because the O(a) errors have been removed.

A simple linear fit to the ratio of decay constants with improvement gives f_{π'}/f_π = 0.078(93) in the chiral limit. The data at κ = 0.1358 is important to in producing a smaller extrapolated ratio of decay constants. A simple linear extrapolation of the two heavier points gives f_{π'}/f_π = 0.16. For the unimproved decay constants, we obtain f_{π'}/f_π = 0.38(11) in the chiral limit. The modest suppression of the f_{π'} decay constant when no improvement factors are used is
consistent with the effective plots of the axial to pseudo-scalar channel looking
similar to the pseudo-scalar to pseudo-scalar channel in figure 1. Although figure 2 could be viewed as a triumph of ALPHA’s program of non-perturbative
renormalisation, a controlled continuum extrapolation is required for a definitive
result. Perhaps it is not so surprising that the full ALPHA formulation is required
to see the suppression of the decay constant, because the PCAC relation
is at the heart of the conditions imposed for improvement (determining coeffi-
cients of irrelevant operators) [25]. The increased suppression of the excited
tion decay constant, from the improved current, is caused by the relatively large
non-perturbative value of the coefficient of $c_A$ and the size of $f_{P'}$. In quenched
QCD at $\beta = 6.0$, with a similar lattice spacing to the one used here, the value of
$c_A$ was controversial with different methods giving different results [29, 30]. The
ALPHA collaboration recommends that their formulation is used in a consistent
continuum extrapolation (“working at constant physics”) [26]. Also, there could
be excited state contamination in the coupling $f_{P'}$, that increases its value. To
check the excited state contamination requires a larger variational basis.

In the original paper the UKQCD collaboration noted that the excited state
masses were very close to the mass of three pions [21]. It is not clear to us what
we would expect for an axial current insertion into a three pion state. If we do a
linear extrapolation of the masses of the $\pi'$ meson versus the square of the pion
mass in units of $r_0$ we obtain in the chiral limit: $m_{\pi'} = 1.29 \pm 0.29$ MeV (using
a nominal value of $r_0 = 0.5$ fm). Although the consistency of the extrapolated
mass (within the large errors) with the mass of the $\pi(1300)$ state is good, it
will be more interesting in future studies to monitor the effect of the three pion
decay on the state.

3 Conclusion

We have investigated the leptonic decay constant of the first excited pseudo-
scalar meson. Although our results are consistent with $f_{P'}$, being much smaller
than $f_{\pi}$, a definitive lattice QCD calculation requires a continuum extrapo-
lation. Recent algorithmic improvements have rescued Wilson/clover lattice
calculations from being too computationally expensive with light quark masses,
hence it is now possible to repeat this calculation with more than one lattice
spacing and lighter quarks [31, 32, 33].

The suppression of the excited light pseudo-scalars may have implications
for the proposed restoration of chiral symmetry for highly excited hadrons, sug-
gested by Glozman [34]. If the leptonic decay constant of the excited pseudo-
scalar mesons are suppressed, then the leptonic decay constant of the parity
partners of the pseudo-scalar mesons should also be suppressed. Although, un-
fortunately, lattice QCD is not ideally suited to studying highly excited mesons,
the study of the suppression of the decay constant of the first excited light
pseudo-scalar is an interesting first step. Note that even if lattice QCD cannot
be used to study the proposed restoration of chiral symmetry in the excited
hadron spectrum, it may be able to study the proposed ”restoration of chiral
symmetry” via the eigenvalue spectrum \cite{35,36}.

Following Narison \cite{37}, in \cite{38} we argued that for the light 0++ state a small value for the leptonic decay constant would be a signal for a molecular state. This seems an unlikely interpretation for the smallness of the decay constant of the π’ meson \cite{14}.

The suppression of \( f_{\pi'} \) is a useful “benchmark” that can be used to tune and validate lattice QCD techniques that try to determine the properties of excited states mesons. It is particularly interesting, because it is a consequence of chiral symmetry. Holl et al. \cite{39} also have predictions for the sign of the decay constant of the \( \pi' \) meson that may also be studied using lattice QCD.

4 Acknowledgements

We thank Craig Roberts for bringing this issue to our attention. We thank Alexander Andrianov for comments. This work has been supported in part by the EU Integrated Infrastructure Initiative Hadron Physics (I3HP) under contract RI3-CT-2004-506078. We are grateful to the ULgrid project of the University of Liverpool for computer time. One of the authors (CM) wishes to thank PPARC for the award of a Senior Fellowship.
