Asymptotic-preserving exponential methods for the quantum Boltzmann equation with high-order accuracy

Jingwei Hu† Qin Li‡ and Lorenzo Pareschi§

October 30, 2013

Abstract

In this paper we develop high order asymptotic preserving methods for the spatially inhomogeneous quantum Boltzmann equation. We follow the work in Li and Pareschi [18] where asymptotic preserving exponential Runge-Kutta methods for the classical inhomogeneous Boltzmann equation were constructed. A major difficulty here is related to the non Gaussian steady states characterizing the quantum kinetic behavior. We show that the proposed schemes work with high-order accuracy uniformly in time for all Planck constants ranging from classical regime to quantum regime, and all Knudsen number ranging from kinetic regime to fluid regime. Computational results are presented for both Bose gas and Fermi gas.

Key words. Quantum Boltzmann equation, asymptotic preserving methods, exponential Runge-Kutta schemes.

1 Introduction

The quantum Boltzmann equation (QBE), also known as the Nordheim-Uehling-Uhlenbeck equation, describes the nonequilibrium dynamics of a dilute quantum gas consisting of elementary particles of bosons or fermions [3]. By including quantum mechanical effects in the collisional process, the equation models a wider range of particle behaviors than the usual Boltzmann equation of classical particles. This is because the latter can be treated as a sub-model under a certain classical limit (Planck constant approaching zero). The QBE and its variants have many applications in science and engineering, including the kinetic description of Bose-Einstein condensate [28, 40], and the modeling of electron interactions in semiconductor devices [22, 16].

In this paper we design a class of high order numerical methods for quantum Boltzmann equation, that is accurate and efficient in both kinetic and hydrodynamic regimes for all Planck

constants. In kinetic theory, the time discretization represents a computational challenge in the
construction of numerical methods, especially in stiff regimes, when the collisional scale becomes
dominant over the transport of particles, and the fluid-dynamic limit is achieved. To resolve the
collision term, the time step is severely controlled by the Knudsen number for numerical stability
if explicit schemes are used. On the other hand, the use of implicit schemes allows larger time
steps but presents considerable limitations in most applications since the collision operator is
usually highly nonlinear and nonlocal.

Many techniques have been developed to address such issues in recent years, and we specif-
ically mention the micro-macro decomposition [2], the BGK penalization method [9], and the
exponential Runge-Kutta methods [6, 10]. The feature shared among these techniques is that
the schemes are unconditionally stable, capturing the asymptotic limits automatically without
time being resolved, and are numerically less complicated than other possible approaches, for ex-
ample, the domain decomposition strategies and hybrid methods at different levels [25, 31, 4, 5].
For a nice survey on asymptotic-preserving (AP) scheme for various kinds of systems see, for
instance, the review paper by Jin [15]. In the case of Boltzmann-type kinetic equations we refer
to a recent review by Pareschi and Russo [26].

In this work we extend the asymptotic preserving exponential Runge-Kutta method developed
in [6, 18] to the quantum Boltzmann equation. The extension to the multi-species Boltzmann
equation could be found in [19]. We refer the reader to [12] for an introduction to time integration
exponential techniques. New difficulties in the quantum case would be:

- The steady states are not classical Maxwellian (Gaussian distribution) and to obtain the
  local equilibrium — the quantum Maxwellian (Bose-Einstein or Fermi-Dirac distribution),
  a nonlinear system needs to be inverted;

- The methods developed need to be uniformly high order and efficient for all Planck con-
  stants, and thus capture the classical limit.

An asymptotic-preserving method for the quantum Boltzmann equation has been proposed in [8],
where a first-order IMEX scheme combined with the standard BGK penalization idea was used.
In particular, the classical Maxwellian was suggested in [8] as an alternative to the complicated
quantum Maxwellian for penalty. This replacement saves fairly amount of computational cost,
but the price to pay is the loss of the strong AP property (namely, in the fluid-limit the distri-
bution function should converge in one time step to its physical equilibrium state). Moreover,
as the scheme is of IMEX type, it is hard to extend the method to very high order [7]. In
comparison, our new schemes possess the strong AP property and, in principle, could achieve
arbitrarily high order. As we shall see, the presence of non classical steady states has a profound
influence on the structure of the resulting numerical method.

Let us finally recall that the construction of numerical methods for the full problem involves
also discretization of the space and velocity variables. The latter discretization in particular is a
challenging problem for the Boltzmann equation due to the high-dimensionality of the collision
operator [23, 8, 14] and the occurrence of the Bose-Einstein condensation phenomenon in the
degenerate quantum case [20, 21]. Here, however, we do not discuss further these issues.

The rest of the paper is organized as follows. In Section 2 we review some basic features of
the quantum Boltzmann equation and its Euler limit. We emphasize in particular the differences
between the classical and the quantum equilibrium states. Next in Section 3 we introduce the
general form of the asymptotic-preserving exponential methods for the quantum Boltzmann
equation. The properties of the method are then analyzed in Section 4. Several numerical
examples are reported in Section 5 to show the AP property and the high-order accuracy of the
schemes. We conclude the paper with some remarks in the last section.

2 The quantum Boltzmann equation and its Euler limit

The quantum Boltzmann equation was first formulated by Nordheim, Uehling and Uhlenbeck
from the classical Boltzmann equation through heuristic arguments \[24, 32\]. In its dimensionless
form, the equation writes as:

\[ \partial_t f + v \cdot \nabla_x f = \varepsilon Q_q(f), \quad t \geq 0, \quad x \in \Omega \subset \mathbb{R}^d, \quad v \in \mathbb{R}^d, \quad d = 2, 3, \quad (2.1) \]

where \( f(t, x, v) \) is the phase space distribution function representing the (rescaled) number of
particles that travel with velocity \( v \) at location \( x \) and time \( t \). \( \varepsilon \) is the so-called Knudsen number
defined as the ratio of the mean free path over the typical length scale. It could vary across
scales from \( \varepsilon \sim O(1) \) to \( \varepsilon \ll 1 \), depending on which, the system falls into the kinetic regime or
fluid regime, respectively. The collision operator \( Q_q \) models the interaction between quantum
particles (here and in the rest of the paper, we always use the upper sign to denote the Bose gas
and the lower sign to the Fermi gas):

\[ Q_q(f) = \int_{\mathbb{R}^d} \int_{\mathbb{S}^{d-1}} B(v - v_s, \sigma) [f' f'_s (1 \pm \theta_0 f) (1 \pm \theta_0 f_s) - f f'_s (1 \pm \theta_0 f') (1 \pm \theta_0 f'_s)] d\sigma dv_s, \quad (2.2) \]

where as usual, \( f, f_s, f' \), and \( f'_s \) are short notations for \( f(t, x, v) \), \( f(t, x, v_s) \), \( f(t, x, v') \), and \( f(t, x, v'_s) \). \((v, v_s)\) and \((v', v'_s)\) are the velocities before and after collision:

\[ \begin{cases} 
   v' = \frac{v + v_s}{2} + \frac{|v - v_s|}{2} \sigma, \\
   v'_s = \frac{v + v_s}{2} - \frac{|v - v_s|}{2} \sigma,
\end{cases} \quad (2.3) \]

where \( \sigma \) is the unit vector along \( v' - v'_s \). The collision kernel \( B \) is a nonnegative function that
only depends on \( |v - v_s| \) and \( \cos \theta \) (\( \theta \) is the angle between \( \sigma \) and \( v - v_s \)). For variable hard sphere
(VHS) particles, \( B \) is independent of scattering angle:

\[ B = C \gamma |v - v_s| \gamma, \quad (2.4) \]

where \( \gamma = 0 \) corresponds to the Maxwell molecules, and \( \gamma = 1 \) is the hard sphere model. The
parameter \( \theta_0 \) is some constant proportional to the Planck constant:

\[ \theta_0 = C \hbar^d. \quad (2.5) \]

It characterizes the degree of degeneracy of the system in the sense that when \( \theta_0 \to 0 \), one
recovers the collision operator for classical particles:

\[ Q_c(f) = \int_{\mathbb{R}^d} \int_{\mathbb{S}^{d-1}} B(v - v_s, \sigma) [f' f'_s - f f'_s] d\sigma dv_s. \quad (2.6) \]

\(^1\)Strictly speaking, \( \theta_0 = \left( \frac{2\pi h^2}{m x_0 v_0^3} \right)^d N \), where \( m \) is the particle mass, \( x_0 \) and \( v_0 \) are the typical values of length
and velocity, \( N \) is the total number of particles.
Compared with $Q_c$, the quantum Boltzmann operator $Q_q$ involves more nonlinearity (it is cubic rather than quadratic). This new feature brings more complexities to both theoretical and numerical studies. We are particularly interested in the fluid regime, where macroscopic equations can be derived similarly as the classical case. To this aim, we first summarize the basic properties of $Q_q$.

1. $Q_q$ conserves mass, momentum, and energy:

$$\int_{\mathbb{R}^d} Q_q(f) \, dv = \int_{\mathbb{R}^d} Q_q(f) v \, dv = \int_{\mathbb{R}^d} Q_q(f) |v|^2 \, dv = 0. \quad (2.7)$$

Then if one defines the macroscopic quantities: density $\rho$, average velocity $u$, specific internal energy $e$, stress tensor $P$, and heat flux $q$ as

$$\rho = \int_{\mathbb{R}^d} f \, dv, \quad \rho u = \int_{\mathbb{R}^d} v f \, dv, \quad \rho e = \frac{1}{2} \int_{\mathbb{R}^d} |v - u|^2 f \, dv, \quad (2.8)$$

$$P = \int_{\mathbb{R}^d} (v - u) \otimes (v - u) f \, dv, \quad q = \frac{1}{2} \int_{\mathbb{R}^d} (v - u) |v - u|^2 f \, dv, \quad (2.9)$$

the following local conservation laws can be obtained from equation (2.1) after multiplication by $(1, v, |v|/2)^T$ and integration w.r.t. $v$:

$$\begin{cases}
\partial_t \rho + \nabla_x \cdot (\rho u) = 0, \\
\partial_t (\rho u) + \nabla_x \cdot (\rho u \otimes u + P) = 0, \\
\partial_t \left( \rho e + \frac{1}{2} \rho u^2 \right) + \nabla_x \cdot \left( \left( \rho e + \frac{1}{2} \rho u^2 \right) u + Pu + q \right) = 0.
\end{cases} \quad (2.10)$$

2. $Q_q$ satisfies the Boltzmann’s H-theorem:

$$\int_{\mathbb{R}^d} \ln \frac{f}{1 + \theta_0 f} Q_q(f) \, dv \leq 0. \quad (2.11)$$

Moreover, the equality holds iff $Q_q(f) = 0$ and iff $f$ reaches the local equilibrium — the quantum Maxwellian (also called Bose-Einstein or Fermi-Dirac distribution):

$$\mathcal{M}_q = \frac{1}{\theta_0} \frac{1}{z^{-1} e^{(v-u)^2/2T} + 1}. \quad (2.12)$$

The new macroscopic quantities $z$ and $T$ are the fugacity and temperature. They are related to $\rho$ and $e$ via

$$\begin{cases}
\rho = \frac{(2\pi T)^{\frac{d}{2}}}{\theta_0} Q^{\frac{d}{2}}(z), \\
e = \frac{d}{2T} Q^{\frac{d}{2}+1}(z)
\end{cases} \quad (2.13)$$

where $Q_\nu(z)$ is the Bose-Einstein/Fermi-Dirac function of order $\nu$ [27]:

$$Q_\nu(z) = \frac{1}{\Gamma(\nu)} \int_0^\infty \frac{x^{\nu-1}}{z^{-1} e^x + 1} \, dx, \quad \begin{cases}
0 < z < 1 \quad \text{for Bose gas} \\
0 < z < \infty \quad \text{for Fermi gas}
\end{cases} \quad (2.14)$$
and $\Gamma(\nu) = \int_0^\infty x^{\nu-1}e^{-x} \, dx$ is the Gamma function.

**Remark 2.1.**

- Compared to the classical Maxwellian:

  $$M_c = \frac{\rho}{(2\pi T)^{\frac{d}{2}}} e^{-\frac{(v-u)^2}{2T}},$$

  (2.15)

the quantum Maxwellian $M_q$ is not a Gaussian function, and $z$, $T$ depend nonlinearly on $\rho$ and $e$, the macroscopic quantities that could be readily obtained by taking the moments of $f$. In fact, it is not difficult to see that when $z \ll 1$, $Q_\nu(z)$ behaves like $z$ itself. Therefore, in the system (2.13), if we keep $\rho$ and $T$ fixed, but send $\theta_0 \to 0$, we get

$$\frac{\rho}{(2\pi T)^{\frac{d}{2}}} \approx \frac{z}{\theta_0}, \quad e \approx \frac{d}{2} T.$$  \hspace{1cm} (2.16)

Since $z$ is very small, one can neglect $\mp 1$ in (2.12), which results in

$$M_q \approx \frac{z}{\theta_0} e^{-\frac{(v-u)^2}{2T}} \approx \frac{\rho}{(2\pi T)^{\frac{d}{2}}} e^{-\frac{(v-u)^2}{2T}} = M_c.$$  

(2.17)

On the other hand, if $\theta_0$ is not small, $M_q$ and $M_c$ will be quite different from each other. Figure gives a simple illustration of the aforementioned two regimes, which we will refer to as (nearly) classical regime and quantum regime in the following discussion.

- The physical range of interest for a Bose gas is $0 < z \leq 1$, where $z = 1$ corresponds to the onset of Bose-Einstein condensation (BEC). To avoid singularity, in this paper we do not consider this extreme case. We refer to [20, 21] for some recent results on the construction of numerical methods for the formation of BEC.

### 2.1 The Euler limit

Now as the Knudsen number $\varepsilon \to 0$ in equation (2.1), based on the discussion above, $f$ is driven to the quantum Maxwellian $M_q$. Substituting $M_q$ into (2.9), we see that $P = \frac{d}{2} \rho e I$ and $q = 0$ ($I$ is the identity matrix). Hence the system (2.10) can be closed and yields the following quantum Euler equations:

\[
\begin{align*}
\partial_t \rho + \nabla_x \cdot (\rho u) &= 0, \\
\partial_t (\rho u) + \nabla_x \cdot \left( \rho u \otimes u + \frac{2}{d} \rho e I \right) &= 0, \\
\partial_t \left( \rho + \frac{1}{2} \rho u^2 \right) + \nabla_x \cdot \left( \left( \frac{d}{d} \rho e + \frac{1}{2} \rho u^2 \right) u \right) &= 0.
\end{align*}
\]

(2.18)

Obviously, written in terms of the macroscopic variables $\rho$, $u$, and $e$, this system is exactly the same as classical Euler equations. The form would be much more complicated if everything is denoted in terms of $z$, $u$, and $T$. 

5
Figure 1: Differences between $M_c$ and $M_q$ in (a) the classical regime; (b) the quantum regime. The left column is for Bose gas and the right one is for Fermi gas.
Remark 2.2. By performing a Chapman-Enskog expansion to the next order, one can obtain the quantum Navier-Stokes (NS) system which differs from its classical counterpart [7]. In particular, the viscosity and heat conductivity coefficients not only depend on $\varepsilon$ but also on $\rho$. The design of a numerical scheme which is capable to capture with high accuracy the NS limit is actually under study and will be considered in future work.

3 The asymptotic-preserving (AP) exponential methods

In this section we propose a class of high-order numerical methods for the quantum Boltzmann equation that

- gives accurate solution in both kinetic and fluid regimes, with time discretization not controlled by $\varepsilon$;
- is accurate for both classical and quantum regimes with accuracy analysis independent of $\theta_0$ (or Planck constant $\hbar$).

To this end, we need to go through two steps: we first rewrite the equation (2.1) in an exponential form, and then apply the explicit Runge-Kutta methods on the newly derived equation. The difficulty is two fold: firstly, the equation needs to be reformulated in a way such that explicit Runge-Kutta, under very mild condition, automatically achieves AP property, and secondly, the new terms emerged in the new equation need to be treated with consistent schemes. We address these two difficulties in the following two subsections respectively.

3.1 Reformulation of the equation and basic numerical methods

In this subsection, we reformulate the equation (2.1) in a form such that basic explicit Runge-Kutta methods automatically achieve asymptotic-preserving properties. The idea is adopted from [6, 18]:

$$
\frac{\partial}{\partial t} \left[ (f - M_q)e^{\mu t} \right] = \left[ \frac{Q_q(f) - \mu(M_q - f)}{\varepsilon} - v \cdot \nabla_x f - \partial_t M_q \right] e^{\mu t}.
$$

This equation is derived through simple calculation, and is completely equivalent to the original quantum Boltzmann equation (2.1). However, if explicit methods are applied onto this equation instead of the original one, one could obtain the AP property.

In the equation (3.1), $\mu$ could be any constant independent of time, and $M_q$ is the local quantum Maxwellian function. As it shares the same moments with $f$, we update them through the following equation:

$$
\frac{\partial}{\partial t} \int \phi M_q dv = \frac{\partial}{\partial t} \int \phi f dv = - \int \phi (v \cdot \nabla_x f) dv, \quad \phi = (1, v, |v|/2)^T.
$$

In the derivation we also used the fact that the first $d + 2$ moments of $Q_q$ are all zeros, as mentioned in (2.7).
We then apply the standard Runge-Kutta method to equations (3.1) and (3.2). The simplest example is the forward Euler scheme:

\[
\begin{cases}
(f^{n+1} - M_q^{n+1})e^\lambda = (f^n - M_q^n) + \frac{h}{\varepsilon} \left[P^n - \mu M_q^n - \varepsilon v \cdot \nabla_x f^n - \varepsilon \partial_t M_q^n\right], \\
\phi M_q^{n+1} dv = \int \phi f^{n+1} dv = \int \phi f^n dv - \frac{h}{\varepsilon} \int \phi (v \cdot \nabla_x f^n) dv,
\end{cases}
\]  

(3.3)

where \( h \) is the time step, \( \lambda = \mu h / \varepsilon \), and the operator \( P \) is defined as \( P(f) = Q_q(f) + \mu f \). The more general \( \kappa \)-step explicit Runge-Kutta method gives:

- **Stage \( i \) (\( i = 1, \ldots, \kappa \))**:

\[
\begin{cases}
(f^{(i)} - M_q^{(i)})e^{c_i \lambda} = (f^n - M_q^n) + \sum_{j=1}^{i-1} a_{ij} \frac{h}{\varepsilon} \left[P^{(j)} - \mu M_q^{(j)} - \varepsilon v \cdot \nabla_x f^{(j)} - \varepsilon \partial_t M_q^{(j)}\right] e^{c_j \lambda}, \\
\phi M_q^{(i)} dv = \int \phi f^{(i)} dv = \int \phi f^n dv + \sum_{j=1}^{i-1} a_{ij} \left(-h \int \phi v \cdot \nabla_x f^{(j)} dv\right);
\end{cases}
\]  

(3.4a)

- **Final Stage**:

\[
\begin{cases}
(f^{n+1} - M_q^{n+1})e^\lambda = (f^n - M_q^n) + \sum_{i=1}^{\kappa} b_i \frac{h}{\varepsilon} \left[P^{(i)} - \mu M_q^{(i)} - \varepsilon v \cdot \nabla_x f^{(i)} - \varepsilon \partial_t M_q^{(i)}\right] e^{c_i \lambda}, \\
\phi M_q^{n+1} dv = \int \phi f^{n+1} dv = \int \phi f^n dv + \sum_{i=1}^{\kappa} b_i \left(-h \int \phi v \cdot \nabla_x f^{(i)} dv\right),
\end{cases}
\]  

(3.4b)

where \( f^{(i)} \) stands for the estimation of \( f \) at time \( t = t^n + c_i h \). \( a_{ij}, b_i, \) and \( c_i \) are Runge-Kutta coefficients that satisfy \( \sum_{j=1}^{i-1} a_{ij} = c_i \) and \( \sum_{i=1}^{\kappa} b_i = 1 \). They are usually stored in a Butcher tableau as:

\[
\begin{array}{c|c}
 c & A \\
 \hline
 b^T & 
\end{array}
\]  

(3.5)

Clearly at each stage \( i \), to evaluate \( f^{(i)} \), one needs to find \( M_q^{(i)} \) at the new stage first, and a good approximation of \( \partial_t M_q^{(j)} \) at old stages (this also applies to the final stage).

Before moving to the next step some considerations are necessary.

**Remark 3.1.**

- The above exponential approach applied to equation (3.1) corresponds to the so-called integrating factor method [12]. Here we limit our analysis to this class of schemes, however, we refer to [10, 12, 18] for other possible exponential techniques that can be used to construct other types of AP exponential schemes.

- Reformulation (3.1) holds true for arbitrary function \( M_q \) which shares the same moments with \( f \). We use the local Maxwellian \( M_q \) because this guarantees the strong AP property, as will be proved in Section 4. A simplifying assumption, analyzed in [18], consists in taking \( M_q \) constant along the time stepping so that the term \( \partial_t M_q \) disappears and the scheme simplifies. This choice, although in general less accurate in intermediate regimes, permits to obtain AP schemes with better stability and monotonicity properties. We leave the analysis of this approach in the quantum case for future studies and refer to [18] for further details.
3.2 Computation of $\mathcal{M}_q^{(i)}$ and $\partial_i \mathcal{M}_q^{(j)}$

We now show how to evaluate $\mathcal{M}_q^{(i)}$ and $\partial_i \mathcal{M}_q^{(j)}$ provided $f^{(j)}$, $\mathcal{M}_q^{(j)} (j < i)$ are known from previous stages.

— Computation of $\mathcal{M}_q^{(i)}$.

By definition in (2.12), $\mathcal{M}_q^{(i)}$ is obtained once we have $u^{(i)}$, $z^{(i)}$, and $T^{(i)}$. The second equation in (3.4a) gives the macroscopic quantities $\rho^{(i)}$, $u^{(i)}$, and $e^{(i)}$, and thus to obtain $z^{(i)}$ and $T^{(i)}$, one only needs to invert the system (2.13). Note that the $2 \times 2$ system is nonlinear. In the implementation, we use the standard Newton-iteration. Details about the approximation and inversion of the quantum function $Q_{\nu}(z)$ can be found in [13].

— Computation of $\partial_i \mathcal{M}_q^{(j)}$.

This is the key idea of the scheme. Write $\mathcal{M}_q = \mathcal{M}_q(z, T, u)$, it is not difficult to derive that (we drop the superscript $(j)$ for simplicity)

$$\partial_i \mathcal{M}_q = \mathcal{M}_q(1 \pm \theta_0 \mathcal{M}_q) \left[ \frac{1}{2} \partial_i z + \frac{(v-u)^2}{2T^2} \partial_i T + \frac{v-u}{T} \cdot \partial_i u \right].$$

(3.6)

While $\partial_i \rho$, $\partial_i u$, and $\partial_i e$ can be directly obtained from the macroscopic equations as we shall see, the computation of $\partial_i z$ and $\partial_i T$ is, however, not explicit. Therefore, it is desirable to transform the expression (3.6) in terms of $\partial_i \rho$, $\partial_i u$, and $\partial_i e$. Through the straightforward but cumbersome calculations in the Appendix, we end up with:

$$\partial_i \mathcal{M}_q = \mathcal{M}_q(1 \pm \theta_0 \mathcal{M}_q) \left[ A \partial_i \rho + B \partial_i e + C \cdot \partial_i u \right],$$

(3.7)

where

$$A = \frac{1}{\rho} \left( M(z) + \frac{(v-u)^2}{dT} (1 - N(z)) \right),$$

(3.8)

$$B = \left( \frac{(v-u)^2}{2eT} - \frac{d}{2e} M(z) \right),$$

(3.9)

$$C = \frac{v-u}{T},$$

(3.10)

and $M(z)$ and $N(z)$ are defined by:

$$M(z) = \frac{Q_{\frac{3}{2}}(z)}{(\frac{d}{2} + 1) Q_{\frac{3}{2} - 1}(z) - \frac{dT}{4e} Q_{\frac{3}{2}}(z)},$$

$$N(z) = \frac{Q_{\frac{3}{2} - 1}(z)}{(\frac{d}{2} + 1) Q_{\frac{3}{2} - 1}(z) - \frac{dT}{4e} Q_{\frac{3}{2}}(z)}.$$  

(3.11)

To compute $\partial_i \rho$, $\partial_i u$, and $\partial_i e$, we use equation (3.2) to transform the time derivative into spatial derivative, namely:

$$\begin{align*}
\partial_t \rho &= \partial_t \int \mathcal{M}_q dv = - \int v \cdot \nabla_x f dv := -F_1, \\
\partial_t (pu) &= \partial_t \int v \mathcal{M}_q dv = - \int v (v \cdot \nabla_x f) dv := -F_2, \\
\partial_t (pe + \frac{1}{2} pu^2) &= \partial_t \int \frac{v^2}{2} \mathcal{M}_q dv = - \int \frac{v^2}{2} (v \cdot \nabla_x f) dv := -F_3,
\end{align*}$$

(3.12)

which is

$$\begin{align*}
\partial_t \rho &= -F_1, \\
\partial_t u &= \frac{1}{\rho} (-F_2 + F_1 u), \\
\partial_t e &= \frac{1}{\rho} \left( -F_3 + F_1 e + \frac{1}{2} F_1 u^2 + u \cdot (F_2 - F_1 u) \right).
\end{align*}$$

(3.13)
In this way, we could compute the time derivatives using only spatial discretizations, and
the scheme is automatically consistent with the framework (3.4).

4 Properties of the exponential AP methods

In this section we briefly analyze the numerical scheme. We are going to show that our
scheme is consistent, recovers the classical Boltzmann equation in the classical regime, and is
AP.

1. The classical regime:
In the classical regime, $\theta_0$ (or the Planck constant) is considered as a very small number,
and the fugacity $z \to 0$. In this regime, theoretically, the quantum Boltzmann equation
recovers the classical Boltzmann equation, and our schemes should reflect this consistency.
For $z \ll 1$, as we have seen previously $Q(\nu) \approx z$, and $e \approx \frac{d^2}{2} T$. By definition, $M(z), N(z) \approx 1$. Plugging these relations back into

\begin{equation}
\frac{1}{\rho} \partial_t \rho + \left( \frac{d}{2e^2} (v-u)^2 - \frac{d}{2e} \right) \rho \frac{d}{dt} e + \frac{d}{2e} (v-u) \cdot \partial_t u.
\end{equation}

(4.2)

This is indeed the time evolution of the classical Maxwellian function $\partial_t M_c$;

- equation (2.12): as argued in Remark 2.1, $M_q$ goes to $M_c$;
- equation (2.2): formally $Q_q$ also becomes the classical collision operator $Q_c$ as $\theta_0 \to 0$.

Combining these three arguments, we see that the scheme (3.4) becomes the Exponential
AP method developed for the classical Boltzmann equation in [18]. We successfully recovers
the classical regime.

2. Consistency:
Here we assume the time step $h$ resolves $\varepsilon$. We firstly rewrite the scheme (3.4a) as:

\begin{equation}
f^{(i)} = M_q^{(i)} + (f^n - M_q^n) e^{-c_i \lambda} + \sum_j a_{ij} \frac{h}{\varepsilon} \left[ P^{(j)} - \mu M_q^{(j)} - \varepsilon v \cdot \nabla_x f^{(j)} - \varepsilon \partial_t M_q^{(j)} \right] e^{(c_j - c_i) \lambda}.
\end{equation}

(4.3)

As $h$ is small, we Taylor expand the exponential term, and rewrite $e^{-c_i \lambda} \sim 1 - c_i \lambda$ and
$e^{(c_j - c_i) \lambda} \sim 1 + (c_j - c_i) \lambda$. We keep $O(1)$ and $O(h)$ terms and neglect higher orders, the
scheme becomes:

\begin{equation}
f^{(i)} = \Lambda_1 + \Lambda_h + O(h^2),
\end{equation}

(4.4)

with

\begin{equation}
\Lambda_1 = M_q^{(i)} + f^n - M_q^n;
\end{equation}

(4.5)

\begin{equation}
\Lambda_h = -c_i \lambda(f^n - M_q^n) + \sum_j a_{ij} \frac{h}{\varepsilon} \left[ P^{(j)} - \mu M_q^{(j)} - \varepsilon v \cdot \nabla_x f^{(j)} - \varepsilon \partial_t M_q^{(j)} \right].
\end{equation}

(4.6)
As \( \mathcal{M}_q^{(i)} \) is the Maxwellian obtained with macroscopic quantities evaluated at time \( t^n + c_i h \), and thus the difference \( \mathcal{M}_q^{(i)} - \mathcal{M}_q^n \) is at most order \( h \), therefore, one has
\[
\Lambda_1 = f^n + c_i h \partial_t \mathcal{M}_q^n + \mathcal{O}(h^2).
\] (4.7)

On the other hand, we rewrite \( \Lambda_h \) as:
\[
\Lambda_h = \sum_j a_{ij} h \left( \frac{Q^{(j)}}{\varepsilon} - v \cdot \nabla_x f^{(j)} \right)
+ \sum_j a_{ij} \lambda(f^{(j)} - \mathcal{M}_q^{(j)}) - c_i \lambda(f^n - \mathcal{M}_q^n) - \sum_j a_{ij} h \partial_t \mathcal{M}_q^{(j)}.
\]
As \( f^{(j)} - f^n = \mathcal{O}(h) \), \( \mathcal{M}_q^{(j)} - \mathcal{M}_q^n = \mathcal{O}(h) \), and \( \sum_j a_{ij} = c_i \), we rewrite it as:
\[
\Lambda_h = \sum_j a_{ij} h \left( \frac{Q^{(j)}}{\varepsilon} - v \cdot \nabla_x f^{(j)} \right) - c_i h \partial_t \mathcal{M}_q^n + \mathcal{O}(h^2).
\] (4.8)

Combining equation (4.7) and (4.8), we have
\[
f^{(i)} = f^n + h \sum_j a_{ij} \left( \frac{Q^{(j)}}{\varepsilon} - v \cdot \nabla_x f^{(j)} \right) + \mathcal{O}(h^2),
\] (4.9)
and the consistency of the scheme is obvious. We could perform the same analysis to (3.4b) and the proof will be omitted from here.

3. Asymptotic preserving:
Here we show AP property of the numerical scheme, namely, as \( \varepsilon \to 0 \), the distribution function will automatically capture the solution to the Euler equation. For simplicity, we only show proof for the case when \( 0 \leq c_1 < c_2 < \cdots < c_\kappa < 1 \). The argument presented here will no longer hold if any sub-stage share the same time step, i.e. \( c_i = c_{i+1} \) for some \( i \), but we still have the same conclusion. The proof for that more general case could be found in \[18\].

We still use the formula (4.3). As \( c_i \) monotonically increases, in the zero limit of \( \varepsilon \), \( \lambda \to \infty \) and the second and the third terms in (4.3) vanish, leaving:
\[
f^{(i)} = \mathcal{M}_q^{(i)} + \mathcal{O}(\lambda e^{-c\lambda}) \sim \mathcal{M}_q^{(i)}, \quad i = 1, \ldots, \kappa,
\] with \( c = \min_i |c_{i+1} - c_i| > 0 \). We take the moment of both sides, and combine it with the second equation in the scheme (3.4a):
\[
\int \phi f^{(i)} dv \sim \int \phi f^n dv - \sum_j a_{ij} h \int \phi v \cdot \nabla_x \mathcal{M}_q^{(j)} dv.
\] (4.10)

Similarly for the numerical solution from (3.4b) we obtain
\[
\int \phi f^{n+1} dv \sim \int \phi f^n dv - \sum_i b_i h \int \phi v \cdot \nabla_x \mathcal{M}_q^{(j)} dv.
\] (4.11)

This is exactly how we close the moment system and obtain the Euler equation analytically, and thus we capture the Euler limit. Let us note that the limiting resulting scheme (4.10)-(4.11) is nothing but the Euler limit. Let us note that the underlying explicit Runge-Kutta method, used in the construction of the exponential scheme, applied to the limiting Euler system. Therefore the method is not only consistent but it preserves the order of accuracy in the fluid limit.
5 Numerical Examples

In this section we present several numerical results. The examples are selected to reflect the AP property and high-order accuracy of the scheme we designed in Section 3. Note that both examples are performed for $x$ in 1D and $v$ in 2D. Exp-RK2 is referred to as RK2 in time coupled with second-order Lax-Wendroff scheme with van Leer limiter in space \[17\]. Exp-RK3 is referred to as RK3 in time coupled with standard WENO3 in space \[29\]. The Butcher tableaux of RK2 (midpoint) and RK3 (Heun method \[11\]) we used in computation are given as follows:

\[
\begin{array}{cccc}
0 & 0 & 0 & 0 \\
1/2 & 1/2 & 0 & 1 \\
0 & 2/3 & 0 & 2/3 \\
1/4 & 0 & 3/4 \\
\end{array}
\]

(5.1)

For the velocity discretization, we use 64 points in each direction and perform the fast spectral method \[14\] for Maxwell molecule kernels. Furthermore, functions $M(z)$ and $N(z)$ (in the evaluation of $\partial_t M_q$) have the following simple form when $d = 2$:

\[
M(z) = \frac{Q_1(z)}{2Q_0(z) - \frac{z}{\varepsilon}Q_1(z)}, \quad N(z) = \frac{Q_0(z)}{2Q_0(z) - \frac{z}{\varepsilon}Q_1(z)},
\]

(5.2)

where for

- Bose gas: $Q_1(z) = -\ln(1-z)$, $Q_0(z) = \frac{1}{1-z}$;
- Fermi gas: $Q_1(z) = \ln(1+z)$, $Q_0(z) = \frac{1}{1+z}$.

5.1 Sod problem

In this subsection we compute a Sod problem. In this problem, in the limiting Euler regime, the solution should have a shock, a rarefaction and a contact discontinuity. The initial data for the macroscopic quantities are chosen as:

\[
\begin{cases}
\rho = 1, \quad u_x = 0, \quad u_y = 0, \quad T = 1; \\
\rho = 0.125, \quad u_x = 0, \quad u_y = 0, \quad T = 0.25.
\end{cases}
\]

(5.3)

For the microscopic quantities, we choose $f(t = 0)$ to be a summation of two Gaussians, as shown in Figure 2 and thus is far away from the quantum equilibrium. Figures 3 and 4 show the numerical results using our new schemes. We consider both classical regime ($\theta_0 = 0.01$) and quantum regime ($\theta_0 = 9$) (the behaviors of Bose gas and Fermi gas in the classical regime are very close to the classical gas, thus one of them is omitted). In the case when Knudsen $\varepsilon = 0.01$ (kinetic regime), the reference solutions are given by directly applying the forward Euler scheme onto the original Boltzmann equation with the spacial discretization $\Delta x = 1/160$, and time step $h = 1/2560$, and our method uses $\Delta x = 1/80$ and $h = 1/1280$. When $\varepsilon = 10^{-6}$ (fluid regime), for reference data, we could not afford the fine discretization any longer, and thus we directly compute the limiting Euler equation. In contrast, our new scheme only uses $\Delta x = 1/160$ and $h = 1/2560$, much bigger than the Knudsen number $\varepsilon$.

We also measured the difference between the distribution function $f$ and the Maxwellian $M_q$. In Figure 5 we can clearly see that smaller $\varepsilon$ gives faster convergence towards the Maxwellian.
5.2 Convergence rate test

In the second example we show the convergence rate. We use the following smooth initial data:

\[
\begin{align*}
\rho &= 0.3125 + 0.1875 \cos (2\pi x); \\
e &= 0.625 + 0.375 \cos (2\pi x); \\
u_x &= u_y = 0;
\end{align*}
\]  

(5.4)

\(h\) is chosen such that the CFL number is 0.5 (independent of \(\varepsilon\)). Note that this is the unique stability restriction that we must impose in our numerical discretization.

To measure the convergence rate, we check the \(L_1\) error of \(\rho\) and compute the decay rate using:

\[
\text{Error}_i = \max_{t \in [0,t_n]} \frac{\| \rho_i(t) - \rho_{i-1}(t) \|_1}{\| \rho_{i-1}(t) \|_1}.
\]  

(5.5)

Here the notation \(\rho_i\) is \(\rho\) computed on \(2^i \times 20\) (with \(i\) being an integer) grid points. Theoretically, if a numerical scheme is of \(k\)-th order, then the error should decay as: \(\text{Error}_i < C (i)^{-k}\) for \(h\) small enough.

In each subfigure in Figure 6, we show the convergence rate with \(\theta_0 = 1\) and \(\theta_0 = 10^{-2}\) using Exp-RK2 and Exp-RK3. We perform the same test for both Bose gas and Fermi gas in both kinetic regime and fluid regime. The numerical results are in good agreement with our theoretical expectation.

6 Conclusions

In this paper we have extended the numerical approach recently introduced in [18] to the case of the quantum Boltzmann equation. In particular, we have shown how to derive high-order asymptotic preserving schemes which work uniformly with respect to the Planck constant. Numerical results for second and third order methods confirm the robustness and accuracy of the
Figure 3: Sod problem. $\varepsilon = 10^{-2}$ (kinetic regime). The three columns, from the left to the right are for Bose gas in classical regime, Fermi gas in quantum regime and Bose gas in quantum regime. The three rows present density $\rho$, internal energy $e$ and fugacity $z$. 
Figure 4: Sod problem. $\varepsilon = 10^{-6}$ (fluid regime). The three columns, from the left to the right are for Bose gas in classical regime, Fermi gas in quantum regime and Bose gas in quantum regime. The three rows present density $\rho$, internal energy $e$ and fugacity $z$. 
Figure 5: Sod problem. The difference between the distribution function $f$ and the Maxwellian $M_q$ decays in time. The figure on the left is for Bose gas and the right one is for Fermi gas. $\theta_0 = 1$.

present method. We did not tackle the issue of the formation of the Bose-Einstein condensate since this involves also a careful choice of the velocity discretization whereas here we concentrate our attention on the time discretization problem only. In our future research we will focus on these challenging aspects.

Appendix A Derivation of $\partial_t M_q$

In this appendix, we give the details of the derivation of (3.7). Our goal is to represent $\partial_t z$ and $\partial_t T$ in equation (3.6) in terms of $\partial_t \rho$ and $\partial_t e$.

First, combining the two equations in system (2.13) gives

$$Q_{\frac{d}{2}}^{\frac{d}{2}+1}(z) = \theta_0 \left(\frac{d}{4\pi e}\right)^\frac{d}{2} \rho.$$  

Therefore, we define a function $F(z)$ such that

$$y = F(z) = \frac{Q_{\frac{d}{2}}^{\frac{d}{2}+1}(z)}{Q_{\frac{d}{2}+1}(z)},$$  

and a function $G(y)$ such that

$$z = G(y) = F^{-1}(y).$$
Figure 6: Convergence rate test. The left column is for $\epsilon = 1$ and $\epsilon = 10^{-6}$ on the right. The top figures are for Bose gas and the bottom ones are for Fermi gas.
Then we have
\[
G'(y) = \frac{1}{F'(z)} = \frac{Q^{d}_{\frac{d}{2}+1}(z)}{\left(\frac{d}{2} + 1\right) Q^\frac{d}{2}_\frac{d}{2}(z) Q^\frac{d}{2}_{\frac{d}{2}+1}(z) - \frac{d}{2} Q^{\frac{d}{2}-1} \frac{d}{2}_{\frac{d}{2}+1}(z) Q^{\frac{d}{2}+1} \frac{d}{2}(z)}.
\] (A.4)

For the Bose-Einstein/Fermi-Dirac function, one has the following nice property (see [27])
\[
zQ'_\nu(z) = Q_{\nu-1}(z).
\] (A.5)

Using (A.5) in (A.4),
\[
G'(y) = \frac{1}{F'(z)} = \frac{z Q^d_{\frac{d}{2}+1}(z)}{\left(\frac{d}{2} + 1\right) Q^\frac{d}{2}_\frac{d}{2}(z) Q^\frac{d}{2}_{\frac{d}{2}+1}(z) - \frac{d}{2} Q^{\frac{d}{2}-1} \frac{d}{2}_{\frac{d}{2}+1}(z) Q^{\frac{d}{2}+1} \frac{d}{2}(z)}
\]
\[
= \frac{z Q^\frac{d}{2+1} \frac{d}{2}(z)}{\left(\frac{d}{2} + 1\right) Q^\frac{d}{2-1} \frac{d}{2}(z) Q^\frac{d}{2+1} \frac{d}{2}(z) - \frac{d}{2} Q^{\frac{d}{2}} \frac{d}{2}(z)}.
\] (A.6)

From the second equation of (2.13) we know
\[
Q^\frac{d}{2+1} \frac{d}{2}(z) = \frac{2e}{dT} Q^\frac{d}{2} \frac{d}{2}(z),
\] (A.7)

then
\[
G'(y) = \frac{z \left(\frac{\pi d}{4 \rho e}\right)^{\frac{d}{2}}}{\left(\frac{d}{2} + 1\right) Q^\frac{d}{2-1} \frac{d}{2}(z) - \frac{2eT}{4e} Q^\frac{d}{2} \frac{d}{2}(z)}.
\] (A.8)

Note that
\[
z = G \left( \theta_0 \left(\frac{d}{4 \pi e}\right)^\frac{d}{2} \rho \right), \quad T = \theta_0 \left(\frac{\rho}{\pi Q^\frac{d}{2} \frac{d}{2}(z)}\right)^{\frac{d}{2}},
\] (A.9)

so we have
\[
\partial_t z = G' \left( \theta_0 \left(\frac{d}{4 \pi e}\right)^\frac{d}{2} \rho \right) \theta_0 \left(\frac{d}{4 \pi e}\right)^\frac{d}{2} \left( \frac{1}{e^2} \partial_t \rho - \frac{d}{2} e^{d+1} \partial_t e \right)
\]
\[
= \frac{z Q^\frac{d}{2} \frac{d}{2}(z)}{\left(\frac{d}{2} + 1\right) Q^\frac{d}{2-1} \frac{d}{2}(z) - \frac{2eT}{4e} Q^\frac{d}{2} \frac{d}{2}(z)} \left( \frac{1}{\rho} \partial_t \rho - \frac{d}{2e} \partial_t e \right);
\] (A.10)

and
\[
\partial_t T = \frac{\theta_0 \frac{d}{2}}{\pi d} \left( \rho^{\frac{d}{2}-1} \frac{Q^d \frac{d}{2}(z)}{Q^\frac{d}{2} \frac{d}{2}(z)} \partial_t \rho - \rho^\frac{d}{2} Q^\frac{d}{2} \frac{d}{2}(z) \partial_t z \right)
\]
\[
= \frac{2T}{d} \rho \partial_t \rho - \frac{2T}{d} \frac{Q^\frac{d}{2-1} \frac{d}{2}(z)}{Q^\frac{d}{2} \frac{d}{2}(z)} \partial_t z = \frac{2T}{d} \frac{Q^\frac{d}{2-1} \frac{d}{2}(z)}{Q^\frac{d}{2} \frac{d}{2}(z)} \left( \frac{1}{\rho} \partial_t \rho - \frac{d}{2e} \partial_t e \right).
\] (A.11)
Therefore,
\[
\begin{align*}
\frac{1}{z} \partial_z + \frac{(v-w)^2}{2T^2} \partial_T &= \frac{Q \frac{d}{2} (z)}{(d \frac{1}{2} + 1) Q \frac{d}{2} - \frac{dT}{4e} Q \frac{d}{2} (z)} \left( \frac{1}{\rho} \partial_t \rho - \frac{d}{2e} \partial_t e \right) \\
+ \frac{(v-w)^2}{dT} \frac{1}{\rho} \partial_t \rho - \frac{(v-u)^2}{dT} \frac{Q \frac{d}{2} - \frac{dT}{4e} Q \frac{d}{2} (z)}{(d \frac{1}{2} + 1) Q \frac{d}{2} - \frac{dT}{4e} Q \frac{d}{2} (z)} \left( \frac{1}{\rho} \partial_t \rho - \frac{d}{2e} \partial_t e \right) \\
&= \left[ \frac{Q \frac{d}{2} (z)}{(d \frac{1}{2} + 1) Q \frac{d}{2} - \frac{dT}{4e} Q \frac{d}{2} (z)} + \frac{(v-w)^2}{dT} \left( 1 - \frac{Q \frac{d}{2} - \frac{dT}{4e} Q \frac{d}{2} (z)}{(d \frac{1}{2} + 1) Q \frac{d}{2} - \frac{dT}{4e} Q \frac{d}{2} (z)} \right) \right] \frac{1}{\rho} \partial_t \rho \\
&+ \left[ \frac{(v-w)^2}{2eT} \frac{Q \frac{d}{2} - \frac{dT}{4e} Q \frac{d}{2} (z)}{(d \frac{1}{2} + 1) Q \frac{d}{2} - \frac{dT}{4e} Q \frac{d}{2} (z)} - \frac{d}{2e} \left( \frac{d}{2} + 1 \right) Q \frac{d}{2} - \frac{dT}{4e} Q \frac{d}{2} (z) \right] \partial_t e.
\end{align*}
\]

(A.12)

Then if we define $M(z)$ and $N(z)$ as in (3.11), (3.7) follows readily from the above equation.
