FILTRATIONS OF TOTALLY REFLEXIVE MODULES

DENISE A. RANGEL TRACY

Abstract. In this paper, we will introduce a subcategory of totally reflexive modules that have a saturated filtration by other totally reflexive modules. We will prove these are precisely the totally reflexive modules with an upper-triangular presentation matrix. We conclude with an investigation of the ranks of $\text{Ext}^1$ of two such modules over a specific ring.

1. Introduction and Preliminaries

Totally reflexive modules were introduced by Auslander and Bridger [1] as modules of Gorenstein dimension zero. It was not until 2002 when Avramov and Martsinkovsky [3] first referred to them as totally reflexive, to better emphasize their homological properties. Over Gorenstein rings, totally reflexive modules are exactly the maximal Cohen-Macaulay modules, whose representation theory is well developed, for example see [12], [14]. However, over non-Gorenstein rings much less is known. Something that is known from [6] is that if there exists a non-free totally reflexive module over a non-Gorenstein local ring with the residue field of characteristic 0, then there exist infinitely many non-isomorphic indecomposable totally reflexive modules over the ring as well. In fact in [5] and [10] infinite families of non-isomorphic indecomposable totally reflexive modules are constructed, both of which arise from exact zero divisors.

Although totally reflexive modules were originally defined for a broader class of rings, for this paper we assume $R$ to be a commutative Noetherian local ring. A finitely generated $R$-module $M$ is called totally reflexive if the biduality map, $\delta : M \rightarrow \text{Hom}_R(\text{Hom}_R(M, R), R)$ is an isomorphism, $\text{Ext}^i_R(M, R) = 0$ and $\text{Ext}^i_R(\text{Hom}_R(M, R), R) = 0$ for all $i > 0$. Projective modules are obviously totally reflexive. We call a nonzero totally reflexive module nontrivial if it is not a projective module. A complex is called acyclic if its homology is zero. A totally acyclic complex is an acyclic complex $\mathbb{A}$ whose dual $\text{Hom}_R(\mathbb{A}, R)$ is...
also acyclic. A module being totally reflexive is equivalent to being a syzygy in a totally acyclic complex of finitely generated free modules. Recall that over a local ring \((R, \mathfrak{m})\) a complex \((\mathcal{F}, \partial)\) of free modules is said to be minimal if \(\text{im} \partial^i \subseteq \mathfrak{m}\mathcal{F}_{i-1}\) for all \(i\).

Throughout this paper we will investigate these modules via their presentation matrix, which is a matrix whose columns are a minimal generating set of the module. Presentation matrices are not unique. However, when over commutative Noetherian local rings two minimal presentation matrices of the same module must be equivalent, see [11].

In this paper, we investigate the structure of totally reflexive modules over local non-Gorenstein Artinian rings by looking at their totally reflexive submodules. We are most interested in the case when the quotient module formed by the totally reflexive module and a totally reflexive submodule is also totally reflexive and of minimal length. If this occurs, then we say that the module has a saturated TR-filtration, see Definition 6 for a more precise description. We prove that knowing if a totally reflexive module has a saturated TR-filtration is directly linked to the existence of a minimal presentation matrix of the module that is upper triangular.

**Theorem.** Let \((R, \mathfrak{m})\) be a non-Gorenstein ring with \(\mathfrak{m}^3 = 0 \neq \mathfrak{m}^2\) that contains exact zero divisors, and suppose that \(T\) is a totally reflexive \(R\)-module. There exists a saturated TR-filtration of \(T\) if and only if \(T\) has an upper triangular presentation matrix.

From this theorem, we obtain two corollaries. Corollary 14 gives further information about the form of this upper triangular presentation matrix. Additionally, Corollary 13 proves the existence of a complete resolution in which every differential can be simultaneously represented by upper triangular matrices. We conclude with an extensive example of the theory, including a study of the number of ways a saturated TR-filtration can occur.

1.1. **Previously Known Results.** Since the results in this paper are proven with the ring being commutative local non-Gorenstein with the cube of the maximal ideal equaling zero, we give two previously known theorems which provide useful facts about these types of rings and totally reflexive modules over them. For a local Artinian ring \((R, \mathfrak{m}, k)\), set \(e = \text{length}(\mathfrak{m}/\mathfrak{m}^2)\) to be the embedding dimension of \(R\).

**Theorem 1.** [15, Theorem 3.1] Let \((R, \mathfrak{m}, k)\) be a commutative local Artinian non-Gorenstein ring with \(\mathfrak{m}^3 = 0 \neq \mathfrak{m}^2\). If there exist a non-trivial totally reflexive \(R\)-module \(T\), then the following conditions hold:
FILTRATIONS OF TOTALLY REFLEXIVE MODULES

(a) \(0 :_R \mathfrak{m} = \mathfrak{m}^2\)

(b) \(\text{length}(0 :_R \mathfrak{m}) = e - 1\), in particular, \(\text{length}(R) = 2e\).

(c) Let \(n\) be the minimal number of generators of \(T\), then \(\text{length}(T) = ne\).

(d) \(T\) has a minimal free resolution of the form
\[ \cdots \to R^n \xrightarrow{d_2} R^n \xrightarrow{d_1} R^n \to T \to 0. \]

**Remark 2.** Part (d) of the previous theorem implies that every differential in a minimal free resolution of \(T\) can be presented by a square matrix. Moreover, any minimal presentation matrix of \(T\) is a square matrix. This fact holds for a complete resolution of \(T\) as well, since any syzygy in a complete resolution of a totally reflexive module is also totally reflexive.

**Theorem 3.** [5, Theorem 5.3] Let \((R, \mathfrak{m})\) be a local ring with \(\mathfrak{m}^3 = 0\) and \(e \geq 3\). Let \(x\) be an element of \(\mathfrak{m}/\mathfrak{m}^2\); the following conditions are equivalent.

(i) The element \(x\) is an exact zero divisor in \(R\).

(ii) The Hilbert series of \(R\) is \(1 + e\tau + (e - 1)\tau^2\), and there exists an exact sequence of finitely generated free \(R\)-modules
\[ \mathbb{F} : F_3 \to F_2 \to F_1 \xrightarrow{\psi} F_0 \to F_{-1} \]
such that \(\text{Hom}_R(\mathbb{F}, R)\) is exact, the homomorphisms are represented by matrices with entries in \(\mathfrak{m}\), and \(\psi\) is represented by a matrix in which some row has \(x\) as an entry and no other entry from \(\mathfrak{m}/\mathfrak{m}^2\).

An exact zero divisor is a special type of ring element, one that is quite significant in these results, see Definition 7.

2. FILTRATIONS AND UPPER TRIANGULAR PRESENTATION MATRICES

Before we present the main theorem of this paper, we need to make note of a few facts when considering modules via their presentation matrices.

**Lemma 4.** Let \((R, \mathfrak{m}, k)\) be a commutative local non-Gorenstein ring with \(\mathfrak{m}^3 = 0 \neq \mathfrak{m}^2\) and \(M\) an \(R\)-module. If a presentation matrix of \(M\) has a column whose entries are contained in \(\mathfrak{m}^2\), then the first syzygy of \(M\) contains a copy of \(k\) as a direct summand.

**Proof.** Let \(\mathfrak{m} = (x_1, \ldots, x_e)\), where \(e\) is the embedding dimension of \(R\), and suppose \(M\) has the presentation matrix \(M = [c_1, \ldots, c_s]\), where
Also, after row and column operations, we may assume that $c_1 \subset m^2 R^{b_0}$. Let
\[
\mathbb{F} : \cdots \to R^{b_2} \xrightarrow{N} R^{b_1} \xrightarrow{M} R^{b_0} \to 0
\]
be a deleted free resolution of $M$. Since $MN = 0$, for $1 \leq i \leq e$ we have that the elements
\[
\begin{pmatrix}
x_i \\
0 \\
\vdots \\
0
\end{pmatrix},
\]
are part of a minimal generating set of the syzygies of $M$. Without loss of generality, assume that $N$ has the form
\[
\begin{pmatrix}
x_1 & \cdots & x_e & 0 & \cdots & 0 \\
0 & \cdots & 0 & * & \cdots & * \\
\vdots & \ddots & \vdots & \ddots & \vdots \\
0 & \cdots & 0 & * & \cdots & *
\end{pmatrix}.
\]
Note that the entries in the first row, after the $e$th column, are all zeroes. This is true since if there was a nonzero entry there, then it would be a linear combination of the first $e$ columns. Therefore, $\text{coker } N \cong k \oplus X$, for some $R$-module $X$. \hfill \Box

**Proposition 5.** Let $(R, m, k)$ be a non-Gorenstein ring with $m^3 = 0 \neq m^2$. If the $n$th syzygy of an $R$-module $M$, $\Omega^R_n(M)$ contains a copy of $k$ as a direct sum, then $M$ is not totally reflexive.

**Proof.** Assume that for some $R$-module $X$, we have $\Omega^R_n(M) \cong k \oplus X$. Now suppose that $M$ is totally reflexive, and therefore, $\Omega^R_n(M)$ is totally reflexive as well since it is a syzygy of $M$. Then, for all $i > 0$, we have $\text{Ext}^i_R(\Omega^R_n(M), R) = 0$ and thus $\text{Ext}^i_R(k \oplus X, R) = 0$ for all $i > 0$, which implies that $\text{Ext}^i_R(k, R) = 0$, for all $i > 0$. This holds if and only if $R$ is Gorenstein. However, we assumed $R$ not to be Gorenstein, and therefore $M$ cannot be totally reflexive. \hfill \Box

**Definition 6.** For a totally reflexive $R$-module $T$, a TR-filtration of $T$ is a chain of submodules
\[
0 = T_0 \subset T_1 \subset \cdots \subset T_{n-1} \subset T_n = T,
\]
in which the following hold for all $i = 1, \ldots, n$:

(i) $T_i$ is totally reflexive
(ii) $T_i/T_{i-1}$ is totally reflexive
(iii) $T_i/T_{i-1}$ contains no proper nonzero totally reflexive submodules.

We say a filtration is a saturated TR-filtration if, in addition, we have that
(iv) $T_i/T_{i-1}$ is of minimal length among the totally reflexive $R$-modules.

In [9] the elements of the ring which play a vital role in the construction of these filtrations are defined as follows.

**Definition 7.** For a commutative ring $A$, a non-unit $a \in A$ is said to be an exact zero divisor if there exists $b \in A$ such that $(0 : a) = (b)$ and $(0 : b) = (a)$. If $A$ is local then $b$ is unique up to unit, and we call $(a, b)$ an exact pair of zero divisors.

This is equivalent to the existence of a free resolution of $A/(a)$ of the form

$$
\cdots \to A \xrightarrow{[b]} A \xrightarrow{[a]} A \xrightarrow{[b]} A \xrightarrow{[a]} A \to 0
$$

**Remark 8.** The complex in Definition 7 is totally acyclic and thus the modules $A/(a)$ and $A/(b)$ are totally reflexive. In fact, in certain cases the reverse is also true.

**Lemma 9.** Let $(R, m)$ be a local ring with $m^3 = 0 \neq m^2$, and let $a \in R$. If $R/(a)$ is a totally reflexive module, then $a$ is an exact zero divisor.

**Proof.** Let $R/(a)$ be a totally reflexive module, and so by Theorem 15 it has a free resolution of the form

$$
\mathbb{F} : \cdots \to R \xrightarrow{b_2} R \xrightarrow{b_1} R \xrightarrow{a} R \to 0.
$$

This implies that $(0 : a) = (b_1)$. Apply the Hom functor, we obtain the complex

$$
\text{Hom}_R(\mathbb{F}, R) : 0 \to \text{Hom}_R(R/(a), R) \to R^{-} \xrightarrow{a^*} R \xrightarrow{b_1^*} R \to \cdots ,
$$

which is exact because $R/(a)$ is totally reflexive. This is isomorphic to

$$
0 \to (R/(a))^* \to R \xrightarrow{a} R \xrightarrow{b_1} R \to \cdots .
$$

Therefore, $\text{ker}(a) = (b_1)$ and we have that $(0 : b_1) = (a)$. Hence $(a, b_1)$ are an exact pair of zero divisors. \hfill \square

**Lemma 10.** Let $(R, m)$ be a non-Gorenstein ring with $m^3 = 0 \neq m^2$ and embedding dimension $e$. If a totally reflexive $R$-module $T$ has a minimal presentation matrix that contains a row with only one nonzero entry, then there exists a totally reflexive submodule $U \subset T$ such that $\text{length } (U) = \text{length } (T) - e$. 

**Proof.** Let

$$
\mathbb{F} : \cdots \to F_2 \xrightarrow{W} F_1 \xrightarrow{T} F_0 \to F_{-1} \to \cdots
$$
be a complete free resolution of $T$, where $W = (\omega_{ij})$ is a presentation matrix of $\Omega^R_1(T)$ and let

$$T = \begin{bmatrix} t_{11} & \cdots & t_{1n} \\ \vdots & \ddots & \vdots \\ t_{n-11} & \cdots & t_{n-1n} \\ 0 & \cdots & 0 & t_{nn} \end{bmatrix}$$

be a presentation matrix of $T$. From Theorem 3 we know that $t_{nn}$ is an exact zero divisor of $R$. Let $s$ generate $(0 : t_{nn})$. Since $TW = 0$, we have that $t_{nn}\omega_{nj} = 0$ for all $j = 1, \ldots, n$. Thus, the ideal $(\omega_{n1}, \ldots, \omega_{nn}) \subset (0 : t_{nn}) = (s)$. This, with Lemma 4, implies that for some $i$ we have $\omega_{ni} = s$, up to units. Therefore, every entry in the $n$th row of $W$ is a multiple of $s$. We can apply column operations to $W$ to assume that

$$W = \begin{bmatrix} w_{11} & \cdots & w_{1n} \\ \vdots & \ddots & \vdots \\ 0 & \cdots & 0 & s \end{bmatrix}$$

is another presentation matrix of $\Omega^R_1(T)$.

Define $W'$ to be the $(n-1)$ by $(n-1)$ matrix obtained by deleting the $n$th row and $n$th column from $W$. Similarly, we define $T'$ to be the $(n-1)$ by $(n-1)$ matrix obtained by deleting the $n$th row and $n$th column from $T$. Note that $W'T' = 0$, and now consider the following commutative diagram:
where \( q := \begin{bmatrix} 1 & 0 \\ \vdots \\ 0 & 1 \end{bmatrix} \) and \( p := \begin{bmatrix} 0 & \ldots & 0 & 1 \end{bmatrix} \). Thus we have an exact sequence of complexes

\[ 0 \to G' \to G \to G'' \to 0 \]

which yields the following long exact sequence of homology.

\[ \cdots \to H_1(G'') \to H_0(G') \to H_0(G) \to H_0(G'') \to 0. \]

Note that \( H_1(G'') = 0 \) since \( R^{[m]} \to R^{[t_{nn}]} \) is exact. Let \( \text{coker} \, T' \) and so \( U \subset T \). Therefore, \( H_0(G'') = R/(t_{nn}) \cong T/U \) and we have the short exact sequence

\[ 0 \to U \to T \to T/U \to 0. \]

To see that \( U \) is in fact totally reflexive, note that \( T/U \cong R/(t_{nn}) \) is totally reflexive since \( (t_{nn}) \) is an exact zero divisor. This, along with the fact that \( T \) is totally reflexive, implies that \( U \) is as well, see [4, Corollary 4.3.5]. From Yoshino’s theorem, here listed as Theorem 1, part (b), we know that the length of \( R/(t_{nn}) \) is the number of its minimal generators times the embedding dimension. Therefore, \( \text{length}(R/(t_{nn})) = e \) and thus \( \text{length}(U) = \text{length}(T) - e. \) □

**Theorem 11.** Let \((R, \mathfrak{m})\) be a non-Gorenstein ring with \( \mathfrak{m}^3 = 0 \neq \mathfrak{m}^2 \) that contains exact zero divisors, and suppose that \( T \) is a totally reflexive \( R \)-module. There exists a saturated \( TR \)-filtration of \( T \) if and only if \( T \) has an upper triangular presentation matrix.

**Proof.** Let \( T \) be totally reflexive \( R \)-module with minimal number of generators \( \mu(T) = n \) and suppose there exists a saturated TR-filtering of \( T \). To show that \( T \) has an upper triangular presentation matrix we will use induction on \( \mu(T) \). If \( \mu(T) = 1 \), then any presentation matrix of \( T \) would be of size \( 1 \times 1 \) and thus trivially upper triangular.

Assuming true for \( \mu(T) = n \), consider the case \( \mu(T) = n + 1 \). By Lemma 10 there exists a totally reflexive \( R \)-module \( M \subset T \) such that the sequence

\[ 0 \to M \to T \to T/M \to 0 \]

is exact and \( T/M \) is cyclic. Define \( N := T/M \) and let \( F \) and \( G \) be free resolutions of \( M \) and \( N \) respectively. Since \( R \) is local with \( \mathfrak{m}^3 = 0 \), we can assume that \( F_i = R^n \) and \( G_i = R \), for all \( i \geq 0 \), [7]. By applying
the Horseshoe Lemma, we get the following diagram:

\[
\begin{array}{c}
\begin{array}{c}
\begin{array}{c}
0 \rightarrow R^n \rightarrow R^n \oplus R \rightarrow R \rightarrow 0
\end{array}
\end{array}
\end{array}
\]

\[
\begin{array}{c}
\begin{array}{c}
\begin{array}{c}
0 \rightarrow R^n \rightarrow R^n \oplus R \rightarrow R \rightarrow 0
\end{array}
\end{array}
\end{array}
\]

where \( d^T_1(f, g) \mapsto d^M_1(f) + \sigma_1(g) \). Since \( d^M_1(f) \in R^n \) and \( \sigma_1(g) \in R^n \oplus R \), when we consider them as columns in a presentation matrix of \( T \) we have the matrix

\[
(2.2) \begin{bmatrix}
  d^M_1 & f' \\
  0 & g'
\end{bmatrix},
\]

where \( \sigma_1(g) = f' + g' \) for some \( f' \in R^n \) and \( g' \in R \), we see that it is upper triangular. This matrix is a presentation matrix of \( T \). By induction, the matrix representing \( d^M_1(f) \) can be taken to be upper triangular and therefore (2.2) is upper triangular.

Now suppose \( T \) has an upper triangular presentation matrix, say

\[
\begin{bmatrix}
t_{11} & \cdots & t_{1n} \\
\vdots & \ddots & \vdots \\
0 & \cdots & t_{nn}
\end{bmatrix}.
\]

Again we will use induction on the minimal number of generators. If \( n = 2 \), then by Lemma 10 there exists a totally reflexive \( R \)-module \( T_1 \cong R/(t_{11}) \) which is a submodule of \( T \). Thus, \( T \) has a saturated TR-filtration

\[
0 = T_0 \subset T_1 \subset T_2 = T
\]

with \( T_2/T_1 \cong R/(t_{22}) \). Now assume that an \( n \)-generated totally reflexive module with an upper triangular presentation matrix has a saturated TR-filtration

\[
0 = T_0 \subset T_1 \subset \ldots \subset T_{n-1} \subset T_n
\]

with \( T_i/T_{i-1} \) being one generated and totally reflexive for \( i = 1, \ldots, n \). Consider an \( (n + 1) \)-generated totally reflexive module \( T \), which has with an upper triangular presentation matrix. By Lemma 10, there
exists a totally reflexive module $T_n$ such that $T_n$ is a submodule of $T$ and has presentation matrix of the form

$$\begin{bmatrix}
t_{11} & \cdots & t_{1n} \\
\vdots & \ddots & \vdots \\
0 & \cdots & t_{nn}
\end{bmatrix}$$

with $T/T_n \cong R/t_{n+1,n+1}$. This, combined with the induction hypothesis, shows that $T$ has a saturated TR-filtration. □

**Definition 12.** An upper triangular complex is a complex in which every differential can simultaneously be represented by a square matrix $(a_{ij})$ such that $a_{ij} = 0$ when $i > j$.

**Corollary 13.** Let $(R, m)$ be a non-Gorenstein ring with $m^3 = 0 \neq m^2$ that contains exact zero divisors. If $T$ is a totally reflexive $R$-module that has an upper triangular minimal presentation matrix, then it has an upper triangular minimal complete resolution.

**Proof.** This will be done by induction on the number of minimal generators. Let $T$ be a totally reflexive $R$-module that has an upper triangular minimal presentation matrix with $\mu(T) = n$. and thus the matrix is of size $n \times n$. Let $\mathbb{F}$ be a free resolution of $T$. By [7, Theorem B], we have that rank$_R F_i = n$ for all $i \in \mathbb{Z}$. If $\mu(T) = 1$, then the free resolution of $T$ is trivially upper triangular.

Assume for $\mu(T) = n$ that $\mathbb{F}$ is an upper triangular minimal free resolution and consider the case when $T$ has a presentation matrix of the form

$$\begin{bmatrix}
t_{11} & \cdots & t_{1,n+1} \\
\vdots & \ddots & \vdots \\
0 & \cdots & t_{n+1,n+1}
\end{bmatrix}.$$

By Theorem 11, there exists an saturated TR-filtration and thus the short exact sequence

$$0 \rightarrow T_n \rightarrow T \rightarrow R/(t_{n+1,n+1}) \rightarrow 0.$$

From the Horseshoe Lemma, a diagram similar to (2.1) can be obtained and extended to include the first syzygies. By a similar argument to the proof of Theorem 11, we see that the first syzygy of $T$ has an upper triangular presentation matrix. Finally, any syzygy in a free resolution of totally reflexive module is also totally reflexive [4]. Therefore, we can apply this corollary to the $n$th syzygy to see that the $n + 1$ the syzygy has an upper triangular presentation matrix. □
Corollary 14. Let \((R, \mathfrak{m})\) be a non-Gorenstein ring with \(\mathfrak{m}^3 = 0 \neq \mathfrak{m}^2\) that contains exact zero divisors. For an \(R\)-module \(M\) that has an upper triangular presentation matrix, the non-zero entries on the main diagonal of that presentation matrix are exact zero divisors if and only if \(M\) is totally reflexive.

Proof. Both directions of this proof rely on the existence of a saturated TR-filtration. First, suppose \(M\) is totally reflexive and has an upper triangular presentation matrix. Hence, we have a saturated TR-filtration
\[
0 = M_0 \subset M_1 \subset \cdots \subset M_{n-1} \subset M_n = M,
\]
as well as short exact sequences
\[
0 \to M_{i-1} \to M_i \to M_i/M_{i-1} \to 0
\]
for all \(i = 2, \ldots, n\). If \(i = 2\), then for some \(u, v, \alpha \in R\) we have
\[
0 \to R/(u) \to \operatorname{coker} \begin{bmatrix} u & \alpha \\ 0 & v \end{bmatrix} \to R/(v) \to 0.
\]
From Lemma 9 both \(u\) and \(v\) are exact zero divisors. Assume this holds for \(n-1\), and consider
\[
0 \to M_{n-1} \to M_n \to M_n/M_{n-1} \to 0.
\]
By the induction hypothesis, \(M_{n-1}\) has a upper triangular presentation matrix with exact zero divisors on the main diagonal. If \(M = (a_{ij})\) is a presentation matrix of \(M_n\), then \(M_n/M_{n-1} \cong R/(a_{nn})\). Since \(R/(a_{nn})\) is totally reflexive, \(a_{nn}\) is an exact zero divisor. Therefore, for all \(i\), \(a_{ii}\) are exact zero divisors.

Now suppose \(M\) has an upper triangular presentation matrix where the non-zero entries on the main diagonal are exact zero divisors. By the inductive part of the proof of Theorem 11, \(M\) is totally reflexive. \(\Box\)

3. Filtrations and Yoneda Ext

Recall that the Yoneda definition [8, Appendix A3] of \(\operatorname{Ext}^1_R(N, M)\) for two \(R\)-modules \(M, N\) gives a correspondence between the elements of \(\operatorname{Ext}^1_R(N, M)\) and equivalence classes of exact sequences of the form
\[
0 \to M \to X \to N \to 0.
\]
If an \(R\)-module \(T\) has a TR-filtration,
\[
0 = T_0 \subset T_1 \subset \cdots \subset T_{n-1} \subset T_n = T,
\]
then there exist short exact sequences
\[
0 \to T_{i-1} \to T_i \to T_i/T_{i-1} \to 0
\]
and hence an element in $\text{Ext}^1_R(T_i/T_{i-1}, T_{i-1})$. In this section, we investigate the number of possible nonequivalent short exact sequences of the above form for a specific ring. We start with brief discussion on the Yoneda definition of $\text{Ext}^1$.

Let
\[
\cdots \to F_2 \xrightarrow{\partial_2} F_1 \xrightarrow{\partial_1} F_0 \to N \to 0
\]
be a free resolution of $N$, and so we have an exact sequence
\[
0 \to \text{im} \partial_1 \to F_0 \to N \to 0.
\]
If we have some $(a + \text{im} \partial_1^*) \in \text{Ext}^1_R(N, M)$, then $a \in \text{Hom}(F_0, M)$. Define $a'$ to be $a$ restricted to $\text{im} \partial_1$ and $\iota$ to be the natural inclusion from $\text{im} \partial_1$ to $F_0$. We can obtain the following commutative diagram using the pushout of $a'$ and $\iota$.

\[
\begin{array}{ccccccccc}
0 & \to & \text{im} \partial_1 & \xrightarrow{\iota} & F_0 & \to & N & \to & 0 \\
\downarrow & & \downarrow & & \downarrow & & \downarrow & & \\
0 & \to & M & \xrightarrow{a'} & (M \oplus F_0)/I & \to & N & \to & 0
\end{array}
\]

where $I = (-a'(r), \iota(r))|r \in \text{im} \partial_1)$. When considering filtrations, $(M \oplus R^b)/I$ is the next larger submodule on the chain of submodules. In order to gain a better understanding of how this translates to a presentation matrix, we will compute this for the second module in a filtration over a specific ring.

For the remainder of this paper, let $S = k[X,Y,Z]/(X^2, Y^2, Z^2, YZ)$, and define $x$, $y$, and $z$ to be the image of $X, Y,$ and $Z$, respectively. Also, let $T_1 = S/(x + by + cz)$ and $N = S/(x + dy + fz)$ where $b, c, d, f \in k$, so they are the cokernel of an exact zero divisor. When considering $\text{Ext}^1_S(N, T_1)$ by the Yoneda definition, a non-zero element of $\text{Ext}^1_S(N, T_1)$ corresponded to a short exact sequence of the form
\[
0 \to T_1 \to T_2 \to N \to 0.
\]
If $\text{Ext}^1_S(N, T_1) \neq 0$, then this will allow us to have a saturated TR-filtration of $T_2$,
\[
0 \subset T_1 \subset T_2.
\]
We now will find a presentation matrix for possible $T_2$.

Let
\[
\mathbb{F}_N : \cdots \to S \xrightarrow{\partial_2} S \xrightarrow{\partial_1} S \xrightarrow{\partial_0} S \to 0
\]
be a (deleted) minimal free resolution of $N$ where
\[
\partial_i = \begin{cases} 
[x + dy + f z], & \text{if } i \text{ is odd} \\
[x - dy - fz], & \text{if } i \text{ is even} 
\end{cases}
\]
For \((a + \im \partial') \in \Ext^1_S(N, T_1)\) where \(\alpha \in \ker(\Hom_S(\partial_2, T_1))\), we have that \(\alpha \in \Hom_S(S, T_1) \cong T_1\). We will identify elements of \(\Hom_S(S, T_1)\) with \(T_1\) under the natural isomorphism. Using the previous description, we find that the push out is \(T_2 := (T_1 \oplus S)/I\). To find a presentation matrix for \(T_2\), we need to find a matrix \(T_2\) in which the following complex is exact

\[
S^2 \xrightarrow{T_2} S^2 \xrightarrow{p} T_2 = (T_1 \oplus S)/I \rightarrow 0.
\]

Take \(e_1, e_2\) to be the standard basis in \(S^2\) and define \(p(e_1) = (\bar{1}, 0) + I\) and \(p(e_2) = (0, 1) + I\). To find the image of \(T_2\) we just need to find the kernel of \(p\) which is shown below.

\[
(x + by + cz)p(e_1) \equiv 0 \quad \text{and} \quad -\alpha p(e_1) + (x + dy + fz)p(e_2) \equiv 0
\]

where \(\alpha \in S/(x + by + cz)\). Therefore, a presentation matrix for \(T_2\) is

\[
T_2 = \begin{bmatrix}
  x + by + cz & -\bar{\alpha} \\
  0 & x + dy + fz
\end{bmatrix},
\]

where \(\bar{\alpha}\) is a preimage of \(\alpha\) in \(S\).

### 3.1. The Rank of \(\Ext^1_S(N, T_1)\)

Since every element in \(\Ext^1\) can be viewed as a short exact sequence, to get a sense of how many nonequivalent sequences exist we study the \(k\)-vector space rank of \(\Ext^1\). As before, let \(T_1 = S/(x + by + cz)\) and \(N = S/(x + dy + fz)\). If

\[
\mathbb{F}_N : \rightarrow S \xrightarrow{\partial_2} S \xrightarrow{\partial_3} S \rightarrow 0
\]

is a (deleted) free resolution of \(N\), then the complex \(\Hom_S(\mathbb{F}_N, T_1)\) has the form

\[
0 \rightarrow T_1 \xrightarrow{\Hom_S(\partial_1, T_1)} T_1 \xrightarrow{\Hom_S(\partial_2, T_1)} T_1 \xrightarrow{\Hom_S(\partial_3, T_1)} T_1 \rightarrow \cdots
\]

and \(\Ext^1_S(N, T_1) = H^1(\Hom_S(\mathbb{F}_N, T_1)) = \ker(\Hom_S(\partial_2, T_1))/\im(\Hom_S(\partial_1, T_1))\). We can compute the kernels and images of these maps:

\[
\ker(\Hom_S(\partial_2, T_1)) = \begin{cases} 
(\bar{1}) \cong T_1, & \text{if } b = -d \text{ and } c = -f \\
(\bar{y}, \bar{z}), & \text{otherwise}
\end{cases}
\]

\[
\im(\Hom_S(\partial_1, T_1)) = ((b - d)\bar{y} + (c - f)\bar{z}).
\]
Therefore,
\[
\text{Ext}_S^1(N, T_1) = \begin{cases} 
T_1/(d - b)\gamma + (f - c)\zeta, & \text{if } b = -d \text{ and } c = -f \\
(\gamma, \zeta)/(d - b)\gamma + (f - c)\zeta, & \text{otherwise,}
\end{cases}
\]
and, provided \(\text{char}(k) \neq 2\), we have
\[
\text{rank}(\text{Ext}_S^1(N, T_1)) = \begin{cases} 
3, & \text{if } b = c = d = f = 0 \\
2, & \text{if } b = -d \text{ and } c = -f, \text{ or if } b = d \text{ and } c = f \\
1, & \text{otherwise.}
\end{cases}
\]

Suppose \((u, v)\) are an exact pair of zero divisors. Then for some \(f_1, f_2 \in k\), we have \(u = x + f_1 y + f_2 z\) and \(v = x - f_1 y - f_2 z\). From the above computations, for some \([\alpha] \in \text{Ext}_S^1(S/u, S/v)\) and some \(S\)-module \(M\), there exists the short exact sequence
\[
\lambda: 0 \to S/v \to M \to S/u \to 0,
\]
where \(M\) has a presentation matrix
\[
M = \begin{bmatrix}
v & -\alpha \\
0 & u
\end{bmatrix}.
\]
In this case, \(1_S\) is a possibility for \(-\alpha\) since \(\mathbb{1} \in \ker(\text{Hom}_S(\partial_2, S/v))\). However
\[
\text{coker } M = \text{coker } \begin{bmatrix} v & 1_S \\ 0 & u \end{bmatrix} \cong S.
\]
This implies that \(\lambda\) represents part of the complete resolution of \(R/v\). Since this is always the case when we have a pair of exact zero divisors, we exclude it to focus on when the non-syzygy cases occurs. Hence, we define \(\Gamma_S(N, T_1)\) to represent the rank of the elements in \(\text{Ext}_S^1(N, T_1)\) which are not part of a complete resolution of \(T_1\). Therefore,
\[
(3.1) \quad \Gamma_S(N, T_1) := \begin{cases} 
2, & \text{if } b = c = d = f = 0 \text{ or } b = d \text{ and } c = f, \\
1, & \text{otherwise.}
\end{cases}
\]

3.2. Bounds on the Ranks of \(\text{Ext}_{R}^1(T_i/T_{i-1}, T_{i-1})\). Let \(T_n\) be a totally reflexive module over \((R, m, k)\) with \(m^3 = 0\) that has an \(n \times n\) upper triangular minimal presentation matrix. From Theorem 1.4 in [5], we know that if there exists one nontrivial totally reflexive modules and if \(k\) is of characteristic zero, then there are infinitely many non-isomorphic indecomposable totally reflexive modules of each admissible length, specifically a multiple of the embedding dimension of the ring. Assume that \(R\) is also a finite dimension \(k\)-algebra. We investigate the
rank of $\text{Ext}_R^1(T_i/T_{i-1}, T_{i-1})$ to get a sense of the complexity (or simplicity) of modules of each possible length. Consider the short exact sequence

$$0 \to T_{i-1} \to T_i \to T_i/T_{i-1} \to 0.$$ 

From this short exact sequence we can obtain a long exact sequence of $\text{Ext}$

$$\cdots \to \text{Ext}_R^1(T_i/T_{i-1}, T_{i-1}) \to \text{Ext}_R^1(T_i/T_{i-1}, T_i) \to \text{Ext}_R^1(T_i/T_{i-1}, T_i/T_{i-1}) \to \cdots.$$ 

We then have the inequality

$$\text{rank}(\text{Ext}_R^1(T_i/T_{i-1}, T_{i-1})) \leq \text{rank}(\text{Ext}_R^1(T_i/T_{i-1}, T_i)) + \text{rank}(\text{Ext}_R^1(T_i/T_{i-1}, T_i/T_{i-1})).$$ 

Now we will find an upper bound for $\Gamma(T_i/T_{i-1}, T_{i-1})$ over the ring $S = k[X, Y, Z]/(X^2, Y^2, Z^2, XYZ)$. By (3.1), if we consider the case when $i = 2$, then we also have that $1 \leq \Gamma(T_2/T_1, T_1) \leq 2$. Therefore

$$\text{rank} \Gamma_S(T_2/T_1, T_2) \leq 4.$$ 

By induction we see that

$$\Gamma_S(T_i/T_{i-1}, T_i) \leq 2n \quad \text{for } i = 2, 3, \ldots.$$ 

In fact, we know of cases when this rank is bounded below by one. That is, there exists a nontrivial short exact sequence beginning in $T_i$ and ending in $T_i/T_{i-1}$. To find such a case, per [5], we define the $b \times b$ upper triangular matrix

$$M_b(s, t, u, v) = \begin{bmatrix} s & u & 0 & 0 & 0 & \cdots \\ 0 & t & v & 0 & 0 & \cdots \\ 0 & 0 & s & u & 0 & \cdots \\ 0 & 0 & 0 & t & v & \cdots \\ 0 & 0 & 0 & 0 & s & \cdots \\ \vdots & \vdots & \vdots & \vdots & \vdots & \ddots \end{bmatrix},$$

and consider the following theorem.

**Theorem 15.** [5, Theorem 3.1] Let $(R, \mathfrak{m})$ be a local ring and assume that $s$ and $t$ are elements in $\mathfrak{m}\setminus\mathfrak{m}^2$ that form an exact pair of zero divisors. Assume further that $u$ and $v$ are elements in $\mathfrak{m}\setminus\mathfrak{m}^2$ with $uv = 0$ and that one of the following conditions holds:

(a) The elements $s, t,$ and $u$ are linearly independent modulo $\mathfrak{m}^2$.

(b) One has $s \in (t) + \mathfrak{m}^2$ and $u, v \notin (t) + \mathfrak{m}^2$.

For every $b \in \mathbb{N}$, the $R$-module $M_b(s, t, u, v)$ is indecomposable, totally reflexive, and non-free. Moreover coker $M_b(s, t, u, v)$ has constant Betti numbers, equal to $b$. 
Over $S$ the all of the exact pairs of zero divisors are of the form $(x + \alpha y + \beta z, x - \alpha y - \beta z)$ for $\alpha, \beta \in k$. Now consider the choices for $u, v \in m \setminus m^2$ whose product is zero. From part (a) of Theorem 15, $x + \alpha y + \beta z, x - \alpha y - \beta z$ and $u$ must be linearly independent in $m / m^2$. For $\gamma, \eta, \lambda, \tau \in k$ let $u = \gamma y + \eta z$ and $v = \lambda y + \tau z$. Therefore, for $\gamma \neq \pm 2\alpha$ and $\eta \neq \pm 2\beta$ we have that $M_6(x + \alpha y + \beta z, x - \alpha y - \beta z, \gamma y + \eta z, \lambda y + \tau z)$ is a presentation matrix of a nontrivial indecomposable totally reflexive $S$-module.

Although Theorem 15 is useful in finding some of the indecomposable totally reflexive modules that have an upper triangular presentation matrix, it says nothing about whether the choices of $s, t, u,$ and $v$ will lead to non-isomorphic modules. In fact, notice that for the choices above of $u$ and $v$ over $S$, neither one of them contains an $x$ term. This is because if either of them did, then one can always find an equivalent presentation matrix, and thus an isomorphic module, which does not have an $x$ term on the super diagonal.

4. Over Finite Fields

Let us now consider the ring $\mathbb{Z}_2[X, Y, Z]/(X^2, Y^2, Z^2, YZ)$. Now we can list the four one-generated totally reflexive modules:

$$(x), \ (x + y), \ (x + z), \ (x + y + z),$$

all of which are non-isomorphic. From here we can construct all possible totally reflexive modules that have a $2 \times 2$ upper triangular presentation matrix, say

$$(4.1) \quad \begin{bmatrix} u & a \\ 0 & t \end{bmatrix}.$$ 

However, there may be many modules that have isomorphic presentation matrices. Recall from [11, Theorem 4.3], that two modules are isomorphic if and only if they have equivalent presentation matrices. To discover which ones do, we start with the assumption that $a$ does not contain an $x$ term. Since $u$ and $t$ both must have an $x$ term, we have that $\begin{bmatrix} u & a \\ 0 & t \end{bmatrix}$ is equivalent to $\begin{bmatrix} u & a - t \\ 0 & t \end{bmatrix}$. Define

$$\mathcal{T} = \{x, x + y, x + z, x + y + z\}$$

and

$$\mathcal{N} = \{y, z, y + z\},$$

and hence $u, t \in \mathcal{T}$ and $a \in \mathcal{N}$. We will also impose an ordering on the elements in $\mathcal{T}$ and $\mathcal{N}$ as the order listed above from smallest to largest. For $i = 1, 2$ let $u_i, t_i \in \mathcal{T}$ and $a_i \in \mathcal{N}$, the for two matrices

$$M_1 = \begin{bmatrix} u_1 & a_1 \\ 0 & t_1 \end{bmatrix} \quad \text{and} \quad M_2 = \begin{bmatrix} u_2 & a_2 \\ 0 & t_2 \end{bmatrix}.$$
define \( M_1 \) to be smaller than \( M_2 \) if
\[
\begin{align*}
    u_1 &< u_2 \quad \text{or} \\
    u_1 &= u_2 \quad \text{and} \quad t_1 < t_2 \quad \text{or} \\
    u_1 &= u_2, \quad t_1 = t_2 \quad \text{and} \quad a_1 < a_2.
\end{align*}
\]

Through the use of the CAS Magma, we can find the isomorphism classes of all totally reflexive modules that have a \( 2 \times 2 \) upper triangular presentation matrix. We chose the smallest presentation matrix to represent each class. There are 24 non-isomorphic indecomposable totally reflexive modules with an upper triangular presentation matrix.

In the below table, we list representatives for each isomorphism class.

For a matrix in the form of \((4.1)\), the options for \( a \) which represent non-isomorphic indecomposable totally reflexive modules are listed in the center of the table.

| \( u \downarrow t \rightarrow \) | \( x \) | \( x+y \) | \( x+z \) | \( x+y+z \) |
|---|---|---|---|---|
| \( x \) | \( y, z, y+z \) | \( z \) | \( y \) | \( y \) |
| \( x+y \) | \( z \) | \( y, z, y+z \) | \( y \) | \( y \) |
| \( x+z \) | \( y \) | \( y \) | \( y, z, y+z \) | \( z \) |
| \( x+y+z \) | \( y \) | \( y \) | \( z \) | \( y, z, y+z \) |

Something to note about these modules when the coefficient field is \( \mathbb{Z}_2 \) is that it is not possible to interchange \( u \) and \( t \), while keeping the same \( a \), and have them be isomorphic to each other. However, this is not the case if instead we consider modules over \( \mathbb{Z}_3[x, y, z]/(x^2, y^2, z^2, yz) \).

Over this ring, a module with presentation matrix \( \begin{bmatrix} u & a \\ 0 & t \end{bmatrix} \) is isomorphic to one with \( \begin{bmatrix} t & a \\ 0 & u \end{bmatrix} \) as a presentation matrix.

Theorem 11 is useful in determining how the totally reflexive submodules of a totally reflexive module are contained in one another in this special case. However, there are totally reflexive modules which do not have an upper triangular presentation matrix and thus do not have a saturated TR-filtration. We conclude with an example of such a module.

5. An example with no upper triangular presentation matrix

Example 16. Consider the \( S \)-module \( T \) with a presentation matrix of
\[
T := \begin{bmatrix} x & z \\ y & x \end{bmatrix},
\]
where $S$ is the same ring defined previously, with $\text{char}(k) = 0$. This is a totally reflexive module. Take a free resolution of it

$$\mathbb{F}_T : \cdots \to S^2 \begin{bmatrix} x & z \\ y & x \end{bmatrix} \to S^2 \begin{bmatrix} x & -z \\ -y & x \end{bmatrix} \to S^2 \begin{bmatrix} x & z \\ y & x \end{bmatrix} \to S^2 \to 0$$

and apply the functor $\text{Hom}_S(\_ , S)$.

$$\text{Hom}_S(\mathbb{F}_T , S) : 0 \to S^2 \begin{bmatrix} x & z \\ y & x \end{bmatrix} \to S^2 \begin{bmatrix} x & -z \\ -y & x \end{bmatrix} \to S^2 \begin{bmatrix} x & z \\ y & x \end{bmatrix} \to S^2 \to \cdots$$

Therefore, $\text{Hom}_S(\mathbb{F}_T , S) \cong \mathbb{F}_T$ and hence the complex $\text{Hom}_S(\mathbb{F}_T , S)$ is also exact. This implies that $T$ is a totally reflexive $S$-module. In particular, this module is not isomorphic to a totally reflexive module that has an upper triangular presentation matrix. This can be done by showing that the matrix $T$ is not equivalent to an upper triangular matrix.

**Proposition 17.** For $T = \begin{bmatrix} x & z \\ y & x \end{bmatrix}$, a totally reflexive $S$-module, the totally reflexive module $T = \text{coker}(T)$ is not isomorphic to a totally reflexive module that has a upper triangular presentation matrix.

**Proof.** Suppose that for an upper triangular matrix $U$ we have $\text{coker} T \cong \text{coker} U$, and hence $T$ would be equivalent to $U$. That is, there would exist two invertible matrices $\begin{bmatrix} a & b \\ c & d \end{bmatrix}$ and $\begin{bmatrix} e & f \\ g & h \end{bmatrix}$ where $a, b, \ldots, h \in k$ such that

$$\begin{bmatrix} a & b \\ c & d \end{bmatrix} T \begin{bmatrix} e & f \\ g & h \end{bmatrix} = U. \quad (5.1)$$

For $\alpha, \beta, \gamma, \zeta, \varphi, \psi$, and $\lambda$ in $k$, let

$$U := \begin{bmatrix} x + \alpha y + \beta z & \zeta x + \varphi y + \psi z \\ 0 & x + \gamma y + \lambda z \end{bmatrix}$$

Computing the products in (5.1) gives us
\[
\begin{pmatrix}
 a & b \\
 c & d \\
\end{pmatrix}
\begin{pmatrix}
 x & z \\
y & x \\
\end{pmatrix}
\begin{pmatrix}
 e & f \\
g & h \\
\end{pmatrix}
= 
\begin{pmatrix}
 x + \alpha y + \beta z & \zeta x + \varphi y + \psi z \\
0 & x + \gamma y + \lambda z \\
\end{pmatrix}
\]

\[
\begin{pmatrix}
 (ae + bg) x + bey + agz \\
(ce + dg) x + edy + cgz \\
\end{pmatrix}
\begin{pmatrix}
 (af + bh) x + bfy + ahz \\
(cf - dh) x + dfy + chz \\
\end{pmatrix}
= 
\begin{pmatrix}
 x + \alpha y + \beta z & \zeta x + \varphi y + \psi z \\
0 & x + \gamma y + \lambda z \\
\end{pmatrix}
\].

These yield a system of equations that one can show to be inconsistent. Therefore, \( T \) is not equivalent to \( U \) and thus \( T \) is not isomorphic to another totally reflexive module that has a upper triangular presentation matrix. \( \square \)
