ABSTRACT: We generalize the electric-magnetic (EM) duality in the quantum double (QD) models to the extended QD models of topological orders with gapped boundaries. We also map the extended QD models to the extended Levin-Wen (LW) models with gapped boundaries. To this end, we Fourier-transform and rewrite the extended QD model on a trivalent lattice with a boundary, where the bulk gauge group is a finite group G. Gapped boundary conditions of the model before the transformation are known to be characterized by the subgroups K ⊆ G supplying the boundary degrees of freedom. We find that after the transformation, the boundary conditions are then characterized by the Frobenius algebras A_{G,K} in Rep_G. An A_{G,K} is the dual space of the quotient of the group algebra of G over that of K, and Rep_G is the category of the representations of G. The EM duality on the boundary is revealed by mapping the K’s to A_{G,K}’s. We also show that our transformed extended QD model can be mapped to an extended LW model on the same lattice via enlarging the Hilbert space of the latter. Moreover, our transformed extended QD model elucidates the phenomenon of anyon splitting in anyon condensation.

1 Introduction

Two-dimensional phases of matter with intrinsic topological orders, or topological phases for short, can be well studied by effective topological field theories, whose Hamiltonian extensions are exactly solvable lattice models. Two major families of such models are the quantum double (QD) models [1] and the string-net models or Levin-Wen (LW) models [2]. The QD models have been generalized to be the twisted QD models [3, 4], and the LW models have also been generalized similarly [5]. In this paper, we shall not deal with such generalizations.

A QD model is a lattice gauge theory with a finite gauge group $G$ as its input data defined on a lattice $\Gamma$. The Hamiltonian of the model converts the input data to an output
data — the quantum double \( D(G) \) of good quantum numbers. The quasiparticle excitations of the topological phase described by the model, namely the anyons, carry representations \( ([c], \mu) \) of \( D(G) \), where \([c]\) labels the conjugacy classes of \( G \), and \( \mu \) labels the irreducible representations of the centralizer of \([c]\) in \( G \). Anyons of the type \(([e], \mu)\) in which \( e \in G \) is the identity element are the pure charges, which live at the vertices of \( \Gamma \); the anyons of the type \(([c], 0)\) with 0 being the trivial representation of the centralizer of \([c]\) are the pure fluxes, which live in the plaquettes of \( \Gamma \); the anyons of the mixed type are the dyons. Hence, intuitively, the QD models would exhibit an explicit EM duality. Indeed, to every QD model on a lattice \( \Gamma \), there corresponds a QD model on the dual lattice \( \Gamma^* \), such that the charges (fluxes) on \( \Gamma \) are the fluxes (charges) on \( \Gamma^* \), and vice versa [6]. This EM duality is immediately understood in the cases of Abelian groups. In such a case, the irreducible representations of \( G \) are all 1-dimensional and form a group isomorphic to \( G \) itself. Denote the set of all irreducible representations of \( G \) by \( \text{Rep}_G \). While the QD model on \( \Gamma \) takes \( G \) as its input data, the dual model on \( \Gamma^* \) takes \( \text{Rep}_G \cong G \) as the input data. That is, the dual model is truly a QD model, which by definition has a finite group as its input data. If \( G \) is non-Abelian, however, \( \text{Rep}_G \) cannot be a group and thus cannot serve as the input data of a QD model. In such cases, the QD models must be generalized to allow Hopf algebras as their input data to exhibit the EM duality [6].

On the other hand, a QD model with a finite group \( G \) can also be mapped via Fourier transform to an LW model with \( \text{Rep}_G \) as its input data on the same lattice [7]. A subtlety is that when \( G \) is non-Abelian, the mapping must come with a truncation of the Hilbert space of the QD model [7] unless one enlarges the Hilbert space of the LW model [6, 8]. Via this mapping, the LW model with input data \( \text{Rep}_G \) bears an EM duality too.

The EM duality in the QD models and the aforementioned mapping to the LW models are restricted to topological phases on closed surfaces only. Nevertheless, topological phases on surfaces with boundaries are of more practical and theoretical importance because 1) materials with boundaries are much more available than the closed ones, 2) boundary modes are easier to measure experimentally, and 3) a dynamical theory of topological phases is incomplete if unable to encompass different boundary conditions. Recently the QD models and LW models have been extended to be defined on lattices with boundaries by adding appropriate boundary Hamiltonians and are called the extended QD models [9, 10] and the extended LW models [11, 12]. We are thus motivated to examine in this paper whether and how the extended QD models still possess an EM duality, in particular along the boundaries, and can be mapped to the extended LW models.

We define our extended QD models on a honeycomb lattice \( \Gamma \) with a single boundary (see figure 1). This convenient choice of lattice leads to no loss of generality because the topological features of the models are invariant under the Pachner moves [10, 12], which preserve the topology of the system despite altering the lattice structure. The input data of an extended QD model on \( \Gamma \) is still a finite group \( G \); however, the boundary Hamiltonian projects the boundary degrees of freedom into a subgroup \( K \subset G \). Each subgroup \( K \) characterizes a gapped boundary condition. Moreover, the boundary Hamiltonian should retain the exactly solvability of the model to guarantee that boundary theory is gapped. It was thought that a fixed boundary subgroup \( K \) alone might not be able to fully specify
a boundary condition because different choices of a 2-cocycle \( \beta \in H^2[K, \mathcal{U}(1)] \) might be used to define different gapped boundary Hamiltonians [9]. This subtlety has a cure, fortunately, as two of us have shown that any two boundary theories specified by \((K, \beta)\) and \((K, \beta')\) with \( \beta \sim \beta' \) can be continuously connected without a phase transition [13] and are thus equivalent. Therefore, we can simply take \((K, 1)\) with 1 the trivial 2-cocycle to define the boundary Hamiltonian, or simply just forget about the 2-cocycles. We first Fourier-transform the Hilbert space on \( \Gamma \) following the similar process as done in the bulk [7, 8] and generalize the method to the boundary. The Fourier-transformed Hilbert space basis begs us to rewrite the Fourier-transformed model on a slightly different lattice \( \tilde{\Gamma} \), which modifies \( \Gamma \) by adding near to each vertex of \( \Gamma \) a dangling edge (see figure 2(d)).

While the bulk degrees of freedom after the Fourier transform become \( \text{Rep}_G \), the boundary degrees of freedom would be projected by the Fourier-transformed boundary Hamiltonian into a Frobenius algebra \( A_{G,K} = (\mathbb{C}[G]/\mathbb{C}[K])^* \), the dual space of the quotient of the group algebra of \( G \) over that of a given \( K \). When \( G \) is Abelian, the emergent Frobenius algebra \( A_{G,K} \) happens to be an Abelian group too; hence, the boundary EM duality can be understood as one between the Fourier-transformed extended QD model on \( \tilde{\Gamma} \) with boundary condition specified by \( A_{G,K} \) and the extended QD model with boundary condition specified by \( K \). When \( G \) is non-Abelian, \( A_{G,K} \) ceases to being a group but truly an algebra.

We also show that our Fourier-transformed extended QD model on \( \tilde{\Gamma} \) can be mapped to an extended LW model on the same lattice. In doing so, instead of truncating the Hilbert space of the extended QD model, we enlarge that of the extended LW model. This enlargement is necessary because the Hilbert space of the original extended LW model is too small to contain the full spectrum of excited states with charges; this has already been done for the original LW model on a closed surface [8]. Since the extended QD models and the extended LW models are Hamiltonian extensions of the extended Dijkgraaf-Witten and extended Turaev-Viro types of topological field theories, our results also offer a correspondence between the two types of topological field theories.

The EM duality on the boundary and the mapping to the extended LW model can be revealed by mapping a \( K \subseteq G \) to \((\mathbb{C}[G]/\mathbb{C}[K])^* \). Three cases of such mappings are listed in Table 1. We explain them in order.

(a) The extended QD model for any \( G \) has a **rough** boundary condition specified by \( K = \{ e \} \), implying charge condensation at the boundary. By a Fourier transform, the extended QD model is mapped to the extended LW model with a boundary Hamiltonian specified by the Frobenius algebra \( A_{G,\{e\}} = \mathbb{C}[G]^* \). As the function space over \( G \), \( \mathbb{C}[G]^* \) is the regular representation in \( \text{Rep}_G \), which has a canonical Frobenius algebra structure that has a decomposition \( A_{G,\{e\}} = \bigoplus_{j \in \text{irrep}_G} V_j^{\oplus \dim V_j} \).

(b) The **smooth** boundary condition is specified by \( K = G \), implying flux condensation at the boundary. The Fourier-transformed boundary Hamiltonian has the trivial input Frobenius algebra \( A_{G,G} = 0 \), the trivial representation in \( \text{Rep}_G \).
| boundary condition | extended QD model | extended LW model |
|---------------------|------------------|------------------|
| charge condensation | $K = \{e\}$     | $A_{G,\{e\}} = \mathbb{C}[G]^*$ (regular rep) |
| flux condensation   | $K = G$          | $A_{G,G} = 0$ (trivial rep) |
| generic dyon condensation | $K$             | $A_{G,K} = (\mathbb{C}[G]/\mathbb{C}[K])^*$ |

Table 1. EM duality on the boundary.

(c) For a nontrivial subgroup $K \subset G$, the corresponding Frobenius algebra is $(\mathbb{C}[G]/\mathbb{C}[K])^*$, which is defined by the function space \( \{f|f(kgk') = f(g)\forall g \in G, \forall k,k' \in K\} \) and is the largest sub-representation space of $\mathbb{C}[G]^*$, such that $\rho(k) = \text{id}, \forall k \in K$.

Another understanding of the boundary EM duality would require generalizing the entire extended QD model to one with input data being a Hopf algebra, similar to what is done only to the bulk as in ref. [6]. We shall not discuss such generalizations in this paper but offer a justification of the boundary EM duality when $G$ is non-Abelian.

According to the mechanism of anyon condensation [14], a gapped boundary condition of a topological phase can be accounted for by a boundary condensate formed by certain types of anyons from the bulk [15, 16]. To condense at the boundary, certain types of bulk anyons would have to first split into a few pieces, several or all of which are allowed to condense at the boundary, depending on the structure of the condensate. Current understandings of this phenomenon are categorical and abstract. It would be interesting to understand the phenomenon of splitting and partial condensation based on concrete lattice models of topological phases. As we will show, our Fourier transform of the extended QD model explains this phenomenon in terms of solely the input data of the model.

To facilitate our studies in the paper, we introduce also a graphical tool of group representation theory. We provide concrete examples, one for Abelian groups $G$ and one for the non-Abelian group $S_3$, to illustrate our results.

Our paper is organized as follows. section 2 reviews the extended QD model. section 3 Fourier-transforms and rewrites the extended QD model. section 4 verifies the emergent Frobenius algebra structure on the boundary and elucidates the phenomenon of anyon splitting in boundary anyon condensation. Section 5 illuminates the boundary EM duality. Section 6 maps the Fourier-transformed extended QD model to the extended LW model on the same lattice. Section 7 provides two concrete examples of our results. Finally, the appendices collect a review of the extended LW model and certain details to avoid clutter in the main text.

2 Extended quantum double model

In this section, we briefly review the extended QD model. An extended QD model [9, 10] is an extension of the QD model to the case with boundaries by adding a boundary Hamiltonian to the QD Hamiltonian. The model is a Hamiltonian extension of the Dijkgraaf-Witten topological gauge theory with a finite gauge group. The model can be defined on an arbitrary lattice with one or multiple boundaries. Topological invariance under the Pachner
Each edge of the lattice is graced with a group element of a finite gauge group $G$. Grey region is the bulk, to the left of the boundary (thick line). Moves allows the model to be defined on a fixed lattice for computational convenience. In this paper, we consider an oriented trivalent lattice $\Gamma$, part of which is shown in figure 1.

The input data of the model is a finite gauge group $G$, whose elements are assigned to the edges of $\Gamma$. The total Hilbert space is spanned by all possible configurations of the group elements of $G$ on the edges of $\Gamma$ and is the tensor product of the local Hilbert spaces respectively on the edges. Namely,

$$\mathcal{H}_{QD}^G = \bigotimes_{e \in \Gamma} \mathcal{H}_e = \bigotimes_{e \in \Gamma} \text{span}\{ |g_e\rangle | g_e \in G \}, \quad (2.1)$$

where $e$ is an edge in $\Gamma$. Note that reversing the orientation of an edge graced with a group element $g$ changes the group element to $\bar{g} := g^{-1}$; however, we work with a fixed lattice with a fixed orientation. The Hamiltonian of the model adds a bulk Hamiltonian and a boundary Hamiltonian:

$$H_{QD}^{G,K} = H_{QD}^{G} + H_{QD}^{K}. \quad (2.2)$$

The bulk Hamiltonian consists of two sums of local operators:

$$H_{QD}^{G} = - \sum_{v \in \Gamma \setminus \partial \Gamma} A_{QD}^v - \sum_{p \in \Gamma \setminus \partial \Gamma} B_{QD}^p, \quad (2.3)$$

where the two sums are respectively over all vertices and all plaquettes in the bulk of $\Gamma$. A local vertex operator $A_{QD}^v$ acts locally on the three edges incident at the vertex $v$ as follows.

$$A_{QD}^v \left| \begin{array}{c} l \cr h \cr v \cr g \end{array} \right\rangle = \frac{1}{|G|} \sum_{x \in G} T(x) \left| \begin{array}{c} l \cr h \cr v \cr xg \end{array} \right\rangle, \quad (2.4)$$

which is understood as a discrete gauge transformation averaged over $G$. Clearly, $A_{QD}^v$ is a projector because $(A_{QD}^v)^2 = A_{QD}^v$ that projects out any such local states that are not invariant under the gauge transformation. In gauge theory terminologies, $A_{QD}^v$ imposes a...
local Gauss constraint. A local plaquette operator acts locally on the six edges outlining the plaquette \( p \) as

\[
B_p^{QD} = \prod_{g_j} \delta_{g_1,g_2,g_3,g_4,g_5,g_6},
\]

which is also a projection. In gauge theory terminologies, \( B_p^{QD} \) imposes a local flatness condition in \( p \). All plaquette operators and vertex operators commute. A gapped boundary condition is specified by a subgroup \( K \subset G \). The boundary Hamiltonian comprises boundary local operators:

\[
H^{QD}_K = -\sum_{v \in \partial \Gamma} \overline{A}_v^{QD} - \sum_{p \in \partial \Gamma} \overline{B}_p^{QD},
\]

where the two sums are respectively over all vertices and virtual plaquettes (to be defined shortly) on the boundary \( \partial \Gamma \) of \( \Gamma \). We define

\[
\overline{A}_v^{QD} = \frac{1}{|K|} \sum_{k \in K} T(k) \overline{A}_v^{QD} \quad \overline{B}_p^{QD} = \frac{1}{|K|} \sum_{k \in K} \overline{B}_p^{QD},
\]

which is again a gauge transformation averaged instead in a subgroup \( K \subset G \). An \( \overline{A}_v^{QD} \) is clearly also a projector that projects out any non-invariant states under its action. All boundary vertex operators commute with each other and with all other operators in the total Hamiltonian. An operator \( \overline{B}_p^{QD} \) simply does the following projection.

\[
\overline{B}_p^{QD} \prod_{g_j} \delta_{x,g_1,g_2,g_3,g_4,g_5} = \delta_{x \in K} \prod_{g_j} \delta_{x,g_1,g_2,g_3,g_4,g_5},
\]

where the virtual plaquette is evidently defined. The boundary plaquette operators all commute. Therefore, the total Hamiltonian (2.2) is exactly solvable. The ground states are the common +1 eigenstates of all operators \( A_v^{QD}, B_p^{QD}, \overline{A}_v^{QD} \) and \( \overline{B}_p^{QD} \). The ground state degeneracy (GSD) can be computed by

\[
GSD = \text{Tr} \prod_{v \in \Gamma \setminus \partial \Gamma} A_v^{QD} \prod_{v' \in \partial \Gamma} \overline{A}_{v'}^{QD} \prod_{p \in \Gamma \setminus \partial \Gamma} B_p^{QD} \prod_{p' \in \partial \Gamma} \overline{B}_{p'}^{QD},
\]

where the trace is taken over the total Hilbert space (2.1). Quasiparticle excitations of the model are charges on the vertices, fluxes through plaquettes, and dyons as bound-states of charges and fluxes. A charge at a vertex \( v \) arises when the local Gauss constraint is violated; a flux through a plaquette \( p \) occurs when the local flatness condition is violated; when both constraints are violated in \( p \), a dyon shows up in \( p \). Other properties of the model and topological phases that are classified by this model can be found in ref. [10] and references therein.
3 Fourier transforming and rewriting the extended QD model

In this section, we Fourier-transform the basis of the Hilbert space of the extended QD model from the group space to the representation space, and as urged by this transformation, rewrite the extended QD model on a slightly different lattice. The Fourier transform of the bulk theory only has been done in refs. [7, 8]; hence, we shall focus on Fourier-transforming the boundary in this section.

3.1 A graphical tool for group representation theory

To facilitate the derivations in this paper, in particular the Fourier transform, we introduce the following graphical tool for group representation theory [17]. Let $L_G$ be the set of all (representatives of equivalence classes of) irreducible representations of a finite group $G$. For simplicity, we shall define $d_\mu = \dim V_\mu$ for $\mu \in L_G$. A representation matrix $D^\mu_{m_\mu n_\mu}(g)$ acting on $V$ is depicted as

\[
\begin{pmatrix}
m_\mu \\
n_\mu
\end{pmatrix}
\]

(3.1)

Here, the line is oriented from the right index $n_\mu$ to the left index $m_\mu$ of the representation matrix. The inline $\oplus$ insertion indicates the group action by $g$. In this graphical presentation, multiplying two representation matrices is synonymously concatenating two such lines:

\[
\sum_{p_\mu} D^\mu_{n_\mu p_\mu}(h) D^\mu_{p_\mu m_\mu}(g) =
\begin{pmatrix}
m_\mu \\
n_\mu
\end{pmatrix}
\]

(3.2)

A line with group action $g = e$ reads as an identity matrix, as in eq. (3.3).

\[
\begin{pmatrix}
m_\mu \\
n_\mu
\end{pmatrix}
\]

(3.3)

which presents the $\dim V_\mu$ basis vectors of the representation space $V_\mu$. Since different representation spaces $V_\mu$ and $V_\nu$ are orthogonal, we can define an inner product $\delta_{m,n} = \langle e_m, e_n \rangle$ with $e_m$ and $e_n$ respectively two basis vectors in $V_\mu$ and $V_\nu$. This inner product is depicted as

\[
\delta_{m,n} \delta_{\mu,\nu} =
\begin{pmatrix}
m \\
n
\end{pmatrix}
\]

(3.4)
Using the inner product (3.4), we can define the complex conjugate of an irreducible representation diagrammatically as

\[
\begin{array}{cccc}
\mu & \leftrightarrow & \mu^* \\
\nu & \rightarrow & \nu^* \\
\end{array}
\]

where the arrow is reversed after the complex conjugation. This way, the complex-conjugated group action should be read upward as \( D^\mu_{m_\mu n_\mu}(g)^* = D^\mu_{n_\mu m_\mu}(\bar{g}) \), with \( \bar{g} := g^{-1} \), because \( g \) is unitary. As such, the great orthogonality theorem is presented by

\[
\sum_{\mu, \nu} \frac{|G|}{d_{\mu, \nu}} \epsilon_{\mu, \nu, \nu^*} = \delta_{\mu, \nu^*}
\]

Every irreducible representation \( \mu \in L_G \) has a dual \( \mu^* \in L_G \), such that \( \mu^* \) is equivalent to (but not necessarily identical to) the complex conjugate representation of \( \mu \). There is an invertible duality map \( \Omega_{m_\mu n_\mu}^{m_{\mu^*} n_{\mu^*}} \) that satisfies normalization \( \Omega^{\dagger} \Omega = I \) and maps \( \mu \) to \( \mu^* \) by similarity transformation

\[
(\Omega^\mu)^{-1} D^\mu(g) \Omega^{\mu} = (D^{\mu^*}(g))^*.
\]

Graphically, the duality map and its inverse are

\[
\Omega_{m_\mu n_\mu}^{m_{\mu^*} n_{\mu^*}} = \sqrt{\frac{\delta_{\mu, \nu^*}}{\delta_{\mu, \nu}}}, \quad (\Omega^\mu)^{-1}_{m_{\mu^*} n_{\mu^*}} = \sqrt{\frac{\delta_{\mu, \nu}}{\delta_{\mu, \nu^*}}}.
\]

And the similarity transformation in eq. (3.8) is presented by

\[
\begin{array}{cccc}
\mu & \rightarrow & \mu^* \\
m_\mu & \rightarrow & n_{\mu^*} \\
\end{array}
\]

For the duality map to be unique, the matrix \( \Omega^\mu \) is either symmetric or antisymmetric depending on whether \( \mu \) is pseudo-real or not. This is an intrinsic property specified by a number \( \beta_{\mu} \) called the Frobenius-Schur (FS) indicator. We have \( (\Omega^\mu)^T = \beta_{\mu} \Omega^\mu \) with \( \beta_{\mu} = \pm 1 \) if \( \mu \) is real or pseudo-real.

Frequently in later derivations, we will need 3j-symbols to deal with the coupling of three representations of \( G \). A 3j-symbol is a tensor \( \omega_{abc}^{m_am_bm_c} \) that is defined as an intertwiner:

\[
V_a \otimes V_b \otimes V_c \rightarrow \mathbb{C}; \quad |am_a, bm_b, cm_c\rangle \rightarrow \omega_{abc}^{m_am_bm_c},
\]

\[\text{(3.11)}\]
where \((a,V_a)\), \((b,V_b)\), and \((c,V_c)\) are three irreducible representations of \(G\), and \(m_j\) labels the basis \(e_{m_j}\) in the vector space \(V_j\). Graphically, a 3\(j\)-symbol is presented by

\[
w_{m_a,m_b,m_c}^{abc} = \begin{array}{c}
a \\
m_a \\
b \\
m_b \\
c \\
m_c \\
\end{array}, \quad \left(w_{m_a,m_b,m_c}^{abc}\right)^* = \begin{array}{c}
a \\
m_a \\
b \\
m_b \\
c \\
m_c \\
\end{array}.
\]  

(3.12)

Being an intertwiner by definition, a 3\(j\)-symbol is invariant under group actions, namely,

\[
\begin{array}{c}
a \\
m_a \\
b \\
m_b \\
c \\
m_c \\
\end{array} = \begin{array}{c}
a \\
m_a \\
b \\
m_b \\
c \\
m_c \\
\end{array}g \quad \text{for any } g \in G.
\]

(3.13)

In this paper, we will also use Clebsch-Gordan coefficients, which are the values of intertwiners and can be defined using the 3\(j\)-symbols (3.12) and duality map (3.9) as

\[
\begin{array}{c}
a \\
m_a \\
b \\
m_b \\
c \\
m_c \\
\end{array} = \begin{array}{c}
a \\
m_a \\
b \\
m_b \\
c \\
m_c \\
\end{array} \otimes \begin{array}{c}
a \\
m_a \\
b \\
m_b \\
c \\
m_c \\
\end{array} = \begin{array}{c}
a \\
m_a \\
b \\
m_b \\
c \\
m_c \\
\end{array} \otimes \begin{array}{c}
a \\
m_a \\
b \\
m_b \\
c \\
m_c \\
\end{array}.
\]

(3.14)

For later convenience, we list a few properties of the 3\(j\)-symbols (Clebsch-Gordan coefficients) as follows. For a generic finite group \(G\), we can always construct such 3\(j\)-symbols satisfying the following properties [17].

\[
\begin{array}{c}
a \\
m_a \\
b \\
m_b \\
c \\
m_c \\
\end{array} = \frac{1}{|G|} \sum_g \begin{array}{c}
a \\
m_a \\
b \\
m_b \\
c \\
m_c \\
\end{array} g \quad \text{for any } g \in G.
\]

(3.15)

where the part in a dashed cap does not have any open edges.

\[
\sum_c \beta_c d_c = \begin{array}{c}
a \\
m_a \\
b \\
m_b \\
c \\
m_c \\
\end{array} = \begin{array}{c}
a \\
m_a \\
b \\
m_b \\
c \\
m_c \\
\end{array} \quad \text{for any } \beta_c \quad \text{and } d_c.
\]

(3.16)

\[
\begin{array}{c}
a \\
m_a \\
b \\
m_b \\
c \\
m_c \\
\end{array} = \frac{1}{d_{\gamma}} \beta_{\gamma} \delta_{m_{\gamma},m_{\gamma'}} \quad \text{for any } \gamma, \gamma'.
\]

(3.17)

\[
\sum_{m_a,m_b,m_c} w_{m_a,m_b,m_c}^{abc}(w_{m_a,m_b,m_c}^{abc})^* = \begin{array}{c}
a \\
m_a \\
b \\
m_b \\
c \\
m_c \\
\end{array} = 1.
\]

(3.18)
Equations (3.16) and (3.17) are the orthogonality conditions, while eq. (3.18) is the normalization condition. The symmetrized $6j$-symbols in terms of the $3j$-symbols and duality map are

$$G_{\eta \rho}^{\mu \nu \lambda} = \sum_{m_\mu, n_\mu, m_\nu, n_\nu, \ldots, m_\rho, n_\rho} \Omega_{m_\mu n_\mu}^{\mu} \Omega_{m_\nu n_\nu}^{\nu} \Omega_{m_\lambda n_\lambda}^{\lambda} \Omega_{m_\eta n_\eta}^{\eta} \Omega_{m_\kappa n_\kappa}^{\kappa} \Omega_{m_\rho n_\rho}^{\rho} \times w_{m_\kappa n_\kappa}^{\kappa \mu \lambda} w_{m_\lambda n_\lambda}^{\lambda \mu \rho} w_{m_\rho n_\rho}^{\rho \mu \eta} w_{m_\eta n_\eta}^{\eta \mu \kappa} w_{m_\kappa n_\kappa}^{\kappa \mu \lambda},$$

which can be presented either by a planar graph or a tetrahedron

$$G_{\eta \rho}^{\mu \nu \lambda} = \beta_{\mu \rho}^{\eta \lambda}.$$

### 3.2 Fourier transform on the Hilbert space

Let us first Fourier-transform the Hilbert space of an extended QD model on $\Gamma$ with a finite gauge group $G$. The total Hilbert space of the model is defined in eq. (2.1). Since the degrees of freedom of the extended QD model live on the edges of the lattice, the total Hilbert space $\mathcal{H}$ is the tensor product of all local Hilbert spaces $\mathcal{H}_e$ on the edges. The local basis state on an edge is $|g\rangle$, which can be Fourier transformed to the basis states in terms of representations $|\mu, m_\mu, n_\mu\rangle$, called a rep-basis, by performing the following Fourier transform (FT):

$$|\mu, m_\mu, n_\mu\rangle = \frac{v_{\mu}}{\sqrt{|G|}} \sum_{g \in G} D_{m_\mu n_\mu}^{\mu}(g) |g\rangle,$$

where $(\mu, V_\mu)$ pairs an irreducible unitary representation of $G$ with representation space $V_\mu$, $v_\mu = \sqrt{d_\mu}$, $|G|$ is the order of $G$, and $D_{m_\mu n_\mu}^{\mu}$ is the representation matrix in $V_\mu$. The local rep-basis and the group-basis have the same dimension because $\sum_\mu d_\mu^2 = |G|$. Note again that the total Hilbert space of the model is defined regardless of the Hamiltonian, which when imposed would separate the Hilbert space into ground and excited states. Hence, the Fourier transform of the group-basis of total Hilbert space on $\Gamma$ can be done by transforming the local basis of the $\mathcal{H}_e$ on each individual edge independently. Figure 2(a) shows a small part of the lattice $\Gamma$, including both bulk and boundary, and a corresponding group-basis state on the part of $\Gamma$. Fourier-transforming a group-basis state in figure 2(a) results in a linear superposition of the rep-basis states, shown in figure 2(b). The explicit transformation will be dealt with a little later. Here we focus on the logic and physics of the basis transformations.

While a basis state in figure 2(a) is directly defined on the original trivalent lattice of the model, a basis state in figure 2(b) lacks the attachment to an actual trivalent lattice. Here is the reason. The Fourier transform turns the three group elements on the three lattice edges meeting at a vertex independently into three linear combinations of all irreducible representations of $G$. Taking the vertex $v_2$ in figure 2(a) as an example, the three group elements $g_2, g_3$ and $g_5$ are respectively transformed into three independent representations...
The basis states are again defined on an actual trivalent lattice $\Gamma$, which differs from the basis states in the Fourier transformation of (a). Now the question is: Can we rewrite the basis in Figure 2(b) to one that has the same dimension and is still attached to an actual trivalent lattice? The answer is “Yes”. Let us again stare at the vertex $v_2$ in Figure 2(b). The strategy is to fuse (i.e., couple) the three representations in an order at $v_2$ following the fusion rules defined by $\mu \otimes \nu = \sum_\eta N_{\mu \nu}^\eta$, where $N_{\mu \nu}^\eta$ are the fusion coefficients (see also appendix A). Since coupling representations is associative and linear, we can choose the order. Let us first fuse $\mu_2$ and $\mu_5$ by contracting their indices $n_2$ and $n_5$, resulting in a linear combination of irreducible representations $\{\eta\}$, each member of which is graphically a line with a free end labeled by $m_\eta$. Then, we can fuse an $\eta$ with $\mu_3$ by contracting $m_\eta$ and $m_3$, resulting in a linear combination of representations $\{s\}$, each member of which is a line with a free end labeled by $m_s$. For each $\eta$ and each $s$, we obtain a new basis state, as in Figure 2(c). A pivotal point is that the degrees of freedom $\eta$ and $s$ are both local with respect to the vertex $v_2$ because they arise from fusing the three representations $\mu_2$, $\mu_5$, and $\mu_3$ at $v_2$. Hence, the line graced with $s$ can be considered an induced degree of freedom at $v_2$, and we place the line as a dangling edge very close to $v_2$. This procedure of rewriting the basis causes no loss of dimension and is thus a linear transformation because the degrees of freedom associated with $v_2$ in Figure 2(c) contribute dimension $\dim = \sum_{\eta, \mu_2, \mu_3, \mu_5} N_{\mu_2 \mu_5}^\eta N_{\mu_3 \mu_5}^\eta d_{\mu_2} d_{\mu_3} d_{\eta} = |G|^3$, which agrees with that contributed by $g_2$, $g_3$, and $g_5$ in Figure 2(a) and that contributed by $\mu_2$, $\mu_3$, and $\mu_5$ in Figure 2(b). Here we used the identities (A.3) and $\sum_{\alpha} d_{\alpha}^2 = |G|$.

We can go through the procedure above on all the other open vertices in Figure 2(c) and obtain the basis states in Figure 2(d), which we shall call the rep-basis states. Now the basis states are again defined on an actual trivalent lattice $\Gamma$, which differs from the
original lattice $\Gamma$ by having a tail anchored near each of the original vertices. The tails are necessary to maintain the correct number of local degrees of freedom. On the new lattice $\tilde{\Gamma}$, each vertex can indeed be interpreted as where three representations fuse. The lattice $\tilde{\Gamma}$ is in fact the right lattice for defining a LW model, such that its Hilbert space contains both charge and dyonic excitations [8]. We will come back to this point later when we map our Fourier-transformed model to the extended LW model in section 6.

Since the vertex and plaquette operators comprising the Hamiltonian of the extend QD model are local operators, the action of such an operator affects only a few local degrees of freedom but not any other. Consider a boundary vertex operator (2.7) acting on the vertex $v_2$ in figure 2(a), it affects only the three group elements meeting at $v_2$. When transformed into the basis in figure 2(d), the vertex operator acting on $v_2$ would possibly affect at most the degrees of freedom $\mu_2, \mu_3, \mu_5, \eta, s, m_3$, which are local at $v_2$. In other words, the other degrees of freedom other than these six are diagonal indices when the vertex operator is represented in the Hilbert space. Therefore, when studying a vertex operator action at a vertex, we can simply single out a local basis-state consisting of only the degrees of freedom local at the vertex.

Let us study the Fourier transform and basis-rewriting depicted in figure 2 by focusing on a local state at a boundary vertex in detail to retrieve the linear transformations of basis with precise coefficients. Consider a local basis-state $|g, h, l\rangle$ drawn on the right hand side of eq. (3.22). In our graphical presentation, Fourier-transforming this basis-state to one in the representation space is as trivial as in eq. (3.22), and the inverse transformation in eq. (3.23).

\[
\begin{align*}
|g, h, l\rangle = \frac{\nu_{\mu} \nu_{\nu} \nu_{\lambda}}{\sqrt{|G|^3}} \sum_{\mu, \nu, \lambda, m_\mu, m_\nu, m_\lambda} n_\mu n_\nu n_\lambda |m_\mu, m_\nu, m_\lambda\rangle,
\end{align*}
\]

In the basis state on the left hand side of eq. (3.22), for any fixed $\mu, \nu, \lambda$, the degrees of freedom are only at the ends of the three lines. We then rewrite the local basis-state on the left hand side of eq. (3.22) by first fusing the two representations $\mu$ and $\nu$ via contracting their indices $m_\mu$ and $m_\nu$, resulting in a set of representations $\{\gamma\}$. Then, we can fuse a $\gamma$ with $\lambda$ by contracting $m_\gamma$ and $m_\lambda$, resulting in a set of representations $\{s\}$. This procedure yields two $3j$-symbols with a pair of indices contracted, resulting in the coefficients of the expansion on the right hand side of eq. (3.24) (also recall figure 2(d)). In the third equality in eq. (3.24), we bend the lines labeled by $\lambda$ and $\mu$ in the coefficients using eq. (3.4). Such bending of lines would make future calculations easier by using eq. (3.17).
To understand the difference between the graphs of the states and those of the coefficients, note that the coefficients are in fact wavefunctions defined by $\Phi(\Gamma) := \langle \Gamma | \Phi \rangle$ with $\Gamma$ a graph. The $\Gamma$ in a state $| \Gamma \rangle$ differs from the $\Gamma$ in $\langle \Gamma | \Phi \rangle$ by parity and opposite edge orientations.

We can denote the new local basis states at the vertex $v$ by $| \Psi_{sm_s} \rangle$ and write down the inverse transformation in eq. (3.25).

$$| \Psi_{sm_s} \rangle := | n_{\nu}, s, m_s \rangle = \sum_{m_\mu, m_\nu, m_\lambda} | \Psi_{sm_s} \rangle = \sum_{m_\mu, m_\nu, m_\lambda} | \Psi_{sm_s} \rangle.$$

Each black dot at a vertex in eqs. (3.24) and (3.25) and in the derivations hereafter represents a $3j$-symbol that ensures an intertwiner space at the vertex. Explanations of the notation $| \Psi_{sm_s} \rangle$ must follow. The linear transformation in eq. (3.24) rewrites only a subspace of the local Hilbert space spanned by the basis on the left hand side of the equation. The subspace is the one comprised by the degrees of freedom $m_\mu, m_\nu,$ and $m_\lambda,$ which are transformed into $\gamma, s,$ and $m_s.$ Hence, the two bases before and after the rewriting both have the same labels $\mu, \nu, \lambda, n_\mu, n_\nu,$ and $n_\lambda.$ Moreover, staring at the right
hand side of eq. (3.24), one can see that the two degrees of freedom $\gamma$ and $s$ cannot be both independent. If we choose $s$ independent, then $\gamma$ is determined by $\mu, \nu, \lambda$, and $s$. Therefore, we can denote the new basis after the rewriting by $|\Psi_{sm_0}\rangle$ for simplicity, while keeping all the other labels in the graph inexplicit. This simplification causes no confusion because in actual calculations, e.g., in computing an inner product of two such local basis states, i.e., $\langle \Psi_{s'm'}|\Psi_{sm_0}\rangle$, the prime in $\Psi'$ implies that the hidden labels in $\Psi'$ should all be the primed version of those in $\Psi$. In the next subsection, we will see another advantage of this simplified notation.

Equations (3.25) and (3.23) lead to a direct linear transformation between the local basis-states in the rep-basis and those in the group-basis at a boundary vertex $v$:

$$|\Psi_{sm_0}\rangle = \sum_{g,h,l \in G} \frac{\nu_{\mu}\nu_{\nu}\nu_{\lambda}\nu_{s}}{\sqrt{|G|^3}} e^{g\mu h\nu l\gamma s} u^\nu g h l. $$

Equations (3.26) and (3.22) in turn can lead to the correct coefficients in eq. (3.24), as shown in appendix C, where we also verify that the local basis states $|\Psi_{sm_0}\rangle$ indeed form a well-defined local basis by showing that it is orthonormal and complete.

### 3.3 Fourier transform of the vertex operators

We are now ready to study how a boundary vertex operator $\overline{A}_v^{QD}$ acts on a local basis-state $|\Psi_{sm_0}\rangle$ in the rep-basis. In other words, we need to find the Fourier-transformed version $\overline{A}_v^{QD}$ of $\overline{A}_v^{QD}$. Two subtleties are in order.

First, a boundary vertex operator $\overline{A}_v^{QD}$ acts on a group-basis local state $|g,h,l\rangle \in \mathcal{H}_v$ by modifying the group elements $g, h,$ and $l$ on the three edges incident at $v$ via gauge transformation. When the group-basis local state is expanded in terms of the local states $|\Psi_{sm_0}\rangle$, the action of $\overline{A}_v^{QD}$ are expected to spread over all the degrees of freedom $\mu, \nu, \lambda, \gamma, s, \text{and } m_s$ local to the vertex $v$. Nevertheless, as we will see, the indices $\mu, \nu, \lambda, \gamma$ are all readily diagonal with respect to the $\overline{A}_v^{QD}$ represented in this local Hilbert space. This further renders $|\Psi_{sm_0}\rangle$ a good notation of the local basis states for $\overline{A}_v^{QD}$, as the other advantage of the notation alluded to earlier.

Second, recall that a bulk vertex operator $A_v^{QD}$ (2.4) acts as a gauge transformation averaged over the entire group $G$; it is a projector that projects out non-intertwiner states of $\mu, \nu,$ and $\lambda$ but keeps the intertwiner states as its $+1$ eigenstates. A boundary vertex operator $\overline{A}_v^{QD}$ (2.7) however performs a gauge transformation averaged over a subgroup $K \subseteq G$. Consequently, $\overline{A}_v^{QD}$ may not project out all non-intertwiner states of $\mu, \nu,$ and $\lambda$. To see this point, let us consider two extreme cases. When $K = G$, $\overline{A}_v^{QD}$ acts exactly the same as a bulk vertex operator and will project out all non-intertwiner states of $\mu, \nu,$ and $\lambda,$ and leaves no degrees of freedom for $s$. That is, the $s$ on the dangling edge (tail) attached
to $v$ must be the trivial representation 0 of $G$. Note that the $\gamma$, as a degree of freedom on an internal edge, is not independent; hence, if $s$ is trivial, $\gamma = v$. When $K = \{e\}$, the action of $A^{QD}_v$ is trivial and thus does not project out any states in the fusion space of $\mu, \nu,$ and $\lambda$. That is, the $s$ can be any irreducible representation of $G$. Now for a generic nontrivial subgroup $K \subset G$, the action of $A^{QD}_v$ may render $s$ taking value in certain subset of the set $L_G$ of all irreducible representations of $G$. Moreover, certain states in $V_s$ may also be projected out. Therefore, the states that survive the action of $A^{QD}_v$ may be labeled by pairs $(s, \alpha_s)$ and collected into a set $L_A = \{(s, \alpha_s)\}$, which is to be defined shortly. The intuitive argument above can be explicitly verified as follows, using eqs. (2.7) and (3.26), and the completeness of the local rep-basis.

$$
\begin{align*}
A^{QD}_v |\Psi_{sm}^s\rangle &= \sum_{\mu, \nu, \delta, s, j, k} A^{QD}_v |g, h, l\rangle |g, h, l\rangle |\Psi_{sm}^s\rangle \\
&= \sum_{g, h, l \in G} \frac{1}{|K|} \sum_{k \in K} D^{s, s'}_{m, m'}(k) |\Psi_{sm'}^s\rangle
\end{align*}
$$

(3.27)

where $P^s_K := \sum_{k \in K} D^{s, s'}_{m, m'}(k)/|K|$. The full version of the above derivation using the graphic tools can be found in appendix C. So, indeed, $A^{QD}_v$ is automatically diagonalized in almost the entire local Hilbert space spanned by $|\Psi_{sm}^s\rangle$ except in the small subspace spanned by $s$ and $m_s$. Besides, $A^{QD}_v$ is clearly block diagonalized by $s$ but within the representation space of $s$, $A^{QD}_v$ is yet not diagonalized. As we know that $A^{QD}_v$ is a projector, the operator $P^s_K$ is actually the matrix representation of $A^{QD}_v$ on the local Hilbert subspace $\mathcal{H}^s_s$ spanned by the states $|\Psi_{sm}^s\rangle$ for a given $s \in L_G$. A linear transformation can be applied to diagonalize the matrix $P^s_K$, which transforms the states $|\Psi_{sm}^s\rangle$ too. Let us rename the states that diagonalize $P^s_K$ by $|\Psi_{sm}^s\rangle$. Hence,

$$
A^{QD}_v |\Psi_{sm}^s\rangle = P^s_K |\Psi_{sm}^s\rangle = \delta(s, \alpha_s) \in L_A |\Psi_{sm}^s\rangle.
$$

(3.28)

Note that for certain $s \in L_G$, $P^s_K$ may project out the entire $\mathcal{H}^s_s$; therefore, the set $L_A$ collects all the +1 eigenstates of $A^{QD}_v$ or its representation $P^s_K$ for all possible $s$ that is not
annihilated by $P_K^s$. That is,

$$L_A = \{(s, \alpha_s)|P_K^s|\Psi_{s\alpha_s}\} = |\Psi_{s\alpha_s}\rangle, s \in L_G \}. \quad (3.29)$$

The states $|\Psi_{s\bar{m}_s}\rangle$ with $(s, \bar{m}_s) \notin L_A$ are the zero eigenstates of $\mathcal{A}_\nu^{QD}$; they have higher energy than the +1 eigenstates according to the Hamiltonian (2.6) and thus are excited states. The excitations appear at the end of the dangling edge graced with representations $s$ and are the point-like charge excitations at the boundary.

### 3.4 Fourier transform of the plaquette operators

We can now proceed to check how a boundary plaquette operator $B_{p}^{QD}$ (2.8) of the extended QD model should be Fourier-transformed to act on a local basis state in the rep-basis. According to eq. (2.8), a $B_{p}^{QD}$ does not act on a vertex but on the edge connecting two vertices. Hence, in the rep-basis, a local basis state on which a $B_{p}^{QD}$ acts would involve two neighbouring vertices and the local degrees of freedom associated with these two vertices. For example, if a $B_{p}^{QD}$ acts on the edge with $g_2$ in figure 2(a), then in figure 2(d), the operator $B_{p}^{QD}$ would act on the degrees of freedom local to the vertices $v_1$ and $v_2$, and all other degrees of freedom correspond to diagonal indices when $B_{p}^{QD}$ is represented in the Hilbert space. Hence, following the same logic as that of constructing the local basis states for the boundary vertex operators, we can denote the local basis states to be acted on by a boundary plaquette operator by $|\Psi_{r\bar{m}_r; s\bar{m}_s}\rangle$, defined as follows.

$$|\Psi_{r\bar{m}_r; s\bar{m}_s}\rangle := \begin{pmatrix}
\lambda \\
\nu
\end{pmatrix}, \quad (3.30)$$

where the indices $\bar{m}_r$ and $\bar{m}_s$ diagonalize the boundary vertex operators acting on $v_1$ and $v_2$ as in eq. (3.28). In eq. (2.8), the boundary plaquette operator $B_{p}^{QD}$ acts on a virtual boundary plaquette $p$, but now in the rep-basis local state (3.30), it acts on a real, open plaquette $p$ outlined by the edges with degrees of freedom $\bar{m}_s, s, \eta, \lambda, r,$ and $\bar{m}_r$.

It is customary to directly compute the matrix elements of a $B_{p}^{QD}$ in the local basis states:

$$\langle \Psi_{r\bar{m}_r; s\bar{m}_s}^{\gamma' \lambda'} | B_{p}^{QD} | \Psi_{r\bar{m}_r; s\bar{m}_s}^{\gamma \lambda} \rangle = \sum_{g, h, l, x, y} \langle \Psi_{r\bar{m}_r; s\bar{m}_s}^{\gamma' \lambda'} | B_{p}^{QD} | g, h, l, x, y \rangle \langle g, h, l, x, y | \Psi_{r\bar{m}_r; s\bar{m}_s}^{\gamma \lambda} \rangle$$

$$= \sum_{g, h, l, x, y} \sum_{(t, \alpha t) \in L_A} \frac{|K|}{|G|} d_t D^l(t) \alpha_t \langle \Psi_{r\bar{m}_r; s\bar{m}_s}^{\gamma' \lambda'} | g, h, l, x, y \rangle \langle g, h, l, x, y | \Psi_{r\bar{m}_r; s\bar{m}_s}^{\gamma \lambda} \rangle \quad (3.31)$$
\[ \sum_{(t, \alpha \in L_A} \sum_{\hat{n}_r, \hat{n}_s, \hat{m}_r, \hat{m}_s} \frac{1}{d_A} \tilde{d}_i \tilde{d}_j \tilde{u}_s \tilde{v}_r \tilde{v}_\chi \tilde{v}_\psi \tilde{v}_\tilde{r} (w_{\tau_{tr}}^{\tau_{rs}})^* (\Omega^r)^{-1}_{\hat{n}_r, \hat{m}_r, \hat{m}_r} \times (w_{\hat{n}_r, \hat{n}_s, \hat{m}_s})^* (\Omega^s)^{-1}_{\hat{n}_r, \hat{n}_s} (\Omega^r)^{-1}_{\hat{m}_r, \hat{m}_s} G_{t, s, r, \psi}^{\mu, \eta^*} G_{t, s, r, \chi}^{\mu, \lambda^*} G_{t, r, \chi}^{\nu, \mu^*} G_{t, r, \psi}^{\nu, \lambda^*} \]

Here, \( \tilde{d}_j = \sqrt{d_j} \) with \( d_j = \beta_j d_j \), and the coefficients \( G_{def}^{abc} \) are the symmetric 6j-symbols of the irreducible representations of the group \( G \); their properties can be found in appendix A or in ref. [17]. The full derivation of the equation above is found in appendix C. The local basis states \( | \Psi^{\eta \lambda}_{\tau_{m_r}, \tau_{m_s}} \rangle \) may be +1 or zero eigenstate of the boundary vertex operators acting on the relevant vertices. It is useful to study the matrix elements of \( \tilde{B}_p^{QD} \) in the local basis states free of any charge excitations, such that boundary pure flux excitations can be identified. To this end, one can act the boundary vertex operators \( \tilde{A}_{\nu_1} \) and \( \tilde{A}_{\nu_2} \) on the states \( | \Psi^{\eta \lambda}_{\tau_{m_r}, \tau_{m_s}} \rangle \) to project out all the charge excitations. Equivalently, we can simply replace the indices \( \hat{m}_r \) and \( \hat{m}_r \) in eq. (3.31) by \( \alpha_r \) and \( \alpha_r \) in eq. (3.29) and obtain

\[ \langle \Psi^{\eta \lambda}_{\tau_{\alpha_r}, \tau_{\alpha_l}, \tau_{\alpha_s}} | \tilde{B}_p^{QD} | \Psi^{\eta \lambda}_{\tau_{\alpha_r}, \tau_{\alpha_l}, \tau_{\alpha_s}} \rangle = \sum_{(t, \alpha \in L_A} \sum_{\hat{n}_r, \hat{n}_s, \hat{m}_r, \hat{m}_s} \frac{1}{d_A} \tilde{d}_i \tilde{d}_j \tilde{u}_s \tilde{v}_r \tilde{v}_\chi \tilde{v}_\psi \tilde{v}_\tilde{r} (w_{\tau_{tr}}^{\tau_{rs}})^* (\Omega^r)^{-1}_{\hat{n}_r, \hat{m}_r, \hat{m}_r} \times (w_{\hat{n}_r, \hat{n}_s, \hat{m}_s})^* (\Omega^s)^{-1}_{\hat{n}_r, \hat{n}_s} (\Omega^r)^{-1}_{\hat{m}_r, \hat{m}_s} G_{t, s, r, \psi}^{\mu, \eta^*} G_{t, s, r, \chi}^{\mu, \lambda^*} G_{t, r, \chi}^{\nu, \mu^*} G_{t, r, \psi}^{\nu, \lambda^*} \]

(3.32)

where \( \tilde{u} = \sqrt{\tilde{u}} \), and in the last equality we define

\[ f_{\alpha_\alpha_\alpha_\alpha_\alpha_\alpha} = \sum_{\hat{m}_r} \tilde{u}_a \tilde{u}_b \tilde{u}_c (w_{\alpha_\alpha_\alpha_\alpha_\alpha_\alpha})^* (\Omega^r)^{-1}_{\hat{m}_r, \hat{m}_r} \]

(3.33)

with \( (a, \alpha_a), (b, \alpha_b), \) and \( (c, \alpha_c) \) being elements in the \( L_A \) defined in eq. (3.29).

We have successfully Fourier-transformed and rewritten the extended QD model on a trivalent lattice \( \tilde{\Gamma} \). In the following sections, we shall study the physical consequences.

4 Emergence of Frobenius algebras and anyon condensation

Interestingly, the Fourier transform and rewriting of the extended QD model leads to an emergent Frobenius algebra structure on the boundary of \( \tilde{\Gamma} \). Namely, the set \( L_A \) defined in eq. (3.29) together with the symbols \( f \) defined in eq. (3.33) form a Frobenius algebra, as an object in the UFC Rep\( G \) — the category of linear representations of \( G \), which is the tensor category generated by \( L_G \) — the set of irreducible representations of \( G \).

Before we show the emergent Frobenius algebra, let us review what Frobenius algebras are. A Frobenius algebra \( A \) is a pair \( (L_A, f) \), where \( L_A \) is the set of elements of \( A \), and \( f \) is the multiplication. An element of \( L_A \) is a pair \( (s, \alpha_s) \) (or just \( \alpha_s \) for short), where \( s \) is a simple object of a UFC \( \mathfrak{g} \). We denote the number of different pairs \( (s, \alpha_s) \) with...
the same $s$ by $|s|$ and call it the multiplicity of $s$ in $A$. The multiplication $f$ is a map: $L_A \times L_A \times L_A \to \mathbb{C}$ that satisfies the following associativity and non-degeneracy.

\begin{align}
\sum_{a \alpha c} f_{a a a b a c} s^* a c f_{c a c r a s^* a c} G^{a b e c}_{r s^* t} \tilde{v}_c \tilde{v}_t &= \sum_{a t} f_{a a a t a s^* a c} f_{b a s r a t^* a t}, \\
\sum_{a \alpha b} f_{b a b} s^* a b &= \delta b b \delta a b a b \beta b,
\end{align}

(4.1a)

(4.1b)

where 0 is the unit element of $A$ and has multiplicity 1, i.e. $0 = (0, 1)$. Here, $\tilde{v}_c = \sqrt{d_c}$, which is defined in appendix A.

That the Frobenius algebra $A$ defined above is an object of the corresponding UFC $\mathfrak{g}$ is understood by writing $A$ as $A = \bigoplus_{s, \alpha} s^s G_{s^s}^s$, which is in general a non-simple object in $\mathfrak{g}$. For the sake of computation, one may also write $A = \bigoplus_{s, \alpha} s^s G_{s^s}^s$, explicitly taking different appearances of $s$ as distinct elements of $A$.

We can show that the symbols $f_{a a a b a c}$ defined in eq. (3.33) indeed satisfy the defining conditions (4.1) of a Frobenius algebra. We first prove the associativity (4.1a) as follows.

\begin{align}
\sum_{a c} f_{a a a b a c} s^* a c f_{c a c r a s^* a c} G^{a b e c}_{r s^* t} \tilde{v}_c \tilde{v}_t \\
= \sum_{a c} \sum_{a n_i, a t_i} \tilde{d}_c \tilde{u}_a \tilde{b} \tilde{t} \tilde{u}_s \tilde{v}_t \left( w^{a b e c}_{a a b n_i} \right)^* \left( \Omega^c \right)^{-1}_{n_i, a c} \left( w^{a b t r}_{a a t a r n_i} \right)^* \left( \Omega^r \right)^{-1}_{n_i, a t} G^{a b e c}_{r s^* t} \\
= \sum_{a c} \sum_{i \in G} \tilde{d}_c \tilde{u}_a \tilde{b} \tilde{t} \tilde{u}_s \tilde{v}_t \beta_t \sum_{a} \sum_{a \alpha t_i} \tilde{d}_c \tilde{u}_a \tilde{b} \tilde{t} \tilde{u}_s \tilde{v}_t \beta_t \\
= \sum_{a \alpha \alpha t_i} \sum_{a \alpha n_i, a t_i} \tilde{u}_a \tilde{b} \tilde{t} \tilde{u}_s \tilde{v}_t \left( w^{a s t e c}_{a a s n_i} \right)^* \left( \Omega^e \right)^{-1}_{n_i, a c} \left( w^{b t r t}_{a a t a r n_i} \right)^* \left( \Omega^r \right)^{-1}_{n_i, a t} \\
= \sum_{a \alpha} f_{a a a t a s^* a c} f_{b a s r a t^* a t},
\end{align}

(4.2)

In the first equality above, we simply rewrite the left hand side using the definition (3.33). The result is then graphically presented via the second equality. The third and fourth equalities are due to eq. (3.15), while the fifth equality due to eq. (3.16). The last equality is again rewriting using definition (3.33). To prove the non-degeneracy condi-
ducible representations of $G$ irreducible representations must appear in $= K A$ Frobenius algebra $K$ discussion earlier in this subsection, a subgroup picture, as we now show, anyon splitting and multiplicity become lucid. According to our anyons should have a non-unit multiplicity in the condensate. In the Fourier-transformed $K$ nevertheless, by the subgroup $G$ condensing all the $G$-tions are specified by the subgroups of $K$ input data of the model. In a concrete lattice model of topological phases with gapped boundaries in terms of the anyon splitting is categorical; hence, it would be important to understand such splitting anyons with quantum dimension greater than or equal to 2. So far, the understanding of condensate if only one (both) of the two pieces condense. Anyon splitting only occurs to condense. If an anyon splits into two pieces, it is said to have multiplicity one (two) in the pieces into a number of anyons do not condense at the boundary straightforwardly; rather, such an anyon may split and the vacuum. An interesting phenomenon is that certain types of anyons may condense and the vacuum. An alternative and equivalent perspective is that there is a gapped domain wall separating $C$ and $U$. In particular in the case where $U$ is a vacuum, we say certain types of anyons of $C$ can move to and condense at the gapped boundary between $C$ and the vacuum. An interesting phenomenon is that certain types of anyons do not condense at the boundary straightforwardly; rather, such an anyon may split into a number of pieces at the boundary, and not all of these pieces can and necessarily condense. If an anyon splits into two pieces, it is said to have multiplicity one (two) in the condensate if only one (both) of the two pieces condense. Anyon splitting only occurs to anyons with quantum dimension greater than or equal to 2. So far, the understanding of anyon splitting is categorical; hence, it would be important to understand such splitting in a concrete lattice model of topological phases with gapped boundaries in terms of the input data of the model.

For the extended QD model with input gauge group $G$, the gapped boundary conditions are specified by the subgroups of $K \subseteq G$. It is known that $K = \{e\}$ corresponds to condensing all the $G$-charges at the boundary, $K = G$ corresponds to condensing all the $G$-fluxes, and any $K$ in between corresponds to condensing certain types of dyons. Nevertheless, by the subgroup $K$ alone one cannot immediately tell whether a type of condensed anyons should have a non-unit multiplicity in the condensate. In the Fourier-transformed picture, as we now show, anyon splitting and multiplicity become lucid. According to our discussion earlier in this subsection, a subgroup $K$ on the boundary of $\Gamma$ gives rise to a Frobenius algebra $A_{G,K} = (L_A, f)_{G,K}$ at the boundary of $\tilde{\Gamma}$. Consider the case where $K = \{e\}$, i.e., charge condensation at the boundary. Then by eqs. (3.28) and (3.29), all irreducible representations must appear in $L_A$. Namely, for any $s \in L_G$, the set of all irreducible representations of $G$, we have \((s, \alpha_s) | \alpha = 1, 2, \ldots, d_s \subset L_A\). Since $s$ labels a type
of pure charge excitations, and since each pair \((s, \alpha_s)\) is an independent element of \(A_{G,K}\), the pure charge \(s\) splits into \(d_s\) pieces, each of which condenses at the boundary. Thus, the multiplicity of the charge \(s\) in the boundary condensate is \(d_s = |s|\), the multiplicity of \(s\) in the Frobenius algebra \(A_{G,K}\). In the case where \(K\) is a nontrivial subgroup, we may have for some \(s\), only a set \(\{(s, \alpha)|\alpha = 1, 2, \ldots, |s| < d_s\}\) \(\subset L_A\). That is although the pure charge \(s\) splits into \(d_s\) pieces, only \(|s|\) pieces of them contribute to the boundary condensate. In section 7.2, we shall see both possibilities in a concrete example.

The Frobenius algebra \(A_{G,K}\) could be understood more intuitively in the language of group algebras \(\mathbb{C}[G]\) and \(\mathbb{C}[K]\). \((\mathbb{C}[G]\) is spanned by the group elements \(\{g \in G\}\), and similarly for \(K\).) To see this, the Frobenius algebra \(A_{G,\{e\}}\) is in fact identified with the canonical Frobenius algebra in \(\text{Rep}_G\), namely, \(A_{\text{canonical}} = \mathbb{C}[G]^* = \text{Fun}(G, \mathbb{C})\) with multiplication \(f \otimes f' \mapsto ff'\) (as a multiplication of functions), and counit \(f \mapsto \sum_{g \in G} f(g)\). The irreducible representations \(\{ \rho_{mn} \}\) form a basis of \(\mathbb{C}[G]^*\). In terms of representations, \(\mathbb{C}[G]^*\) is a left regular representation and can be decomposed into irreducible representations in the form

\[
A_{\text{canonical}} = \bigoplus_{\mu \in L_G} V_{\mu}^{d_{\mu}},
\]

with the multiplication being the 3j-symbol (up to some normalization factor) as defined in eq. (3.33).

Similarly, the Frobenius algebra \(A_{G,K}\) can be identified with \((\mathbb{C}[G]/\mathbb{C}[K])^*\) — the dual space of the quotient \(\mathbb{C}[G]/\mathbb{C}[K]\) — which is the space of all functions \(f\) over \(G\) such that \(f(gk) = f(h)\) if \(gk = h\) or \(kg = h\) for some \(K\). The space \((\mathbb{C}[G]/\mathbb{C}[K])^*\) is a subalgebra of \(\mathbb{C}[G]^*\) and is also a Frobenius algebra with the algebra structure inherited from \(\mathbb{C}[G]^*\). By solving the eigen-equation \(\rho(k) = \text{id}\), we obtained the new basis \(\{ \rho_{\alpha_s} \}\), and in terms of irreducible representations we have

\[
A_{G,K} = \bigoplus_{(s, \alpha_s) \in L_A} V_s^{\alpha_s},
\]

where \(V_s^{\alpha_s}\) denotes the \(\alpha_s\)-th copy of \(V_s\) that appears in \(A_{G,K}\) with the multiplicity index \(\alpha_s\). The multiplication is also the 3j-symbol (up to some normalization factor) as defined in eq. (3.33). By the definition of \(L_A\) in eq. (3.28), \(\alpha_s\) is given by a basis vector such that \(\rho^s(k|s, \alpha_s) = |s, \alpha_s, k\rangle\) for all \(k \in K\). The space \(A_{G,K}\) spanned by \(|s, \alpha_s\rangle\) is thus identified with \((\mathbb{C}[G]/\mathbb{C}[K])^*\) defined above.

5 EM duality in the extended QD model

5.1 EM duality in the bulk

The QD model exhibits an EM duality [6–8]. Let us recap the known results here using our notation. Consider the QD models with finite Abelian groups \(G\). In such a case, all the irreducible representations of \(G\) are 1-dimensional and form a group, with the group multiplication defined as the tensor product of representations. For example, the irreducible representations of \(G = \mathbb{Z}_n\) form the group \(\text{Rep}_G = \mathbb{Z}_n\). Let \(g \in \{0, 1, \ldots, n-1\}\)
Hence, we have \( \operatorname{Rep} j \) where the \( j \) states as the representation space. Hence, the vertex and plaquette operators act on the new basis where the \( g \) and \( p \) becomes a plaquette \( g \) and \( p \) becomes a plaquette Figure 3.

On the other hand, we can draw the dual lattice \( \Lambda^* \) on \( \Gamma \) from the group space to the representation space. Hence, the vertex and plaquette operators act on the new basis states as

\[
A_v |j_1, j_2, j_3 \rangle_v = \delta_{j_1, j_2, j_3, 0} |j_1, j_2, j_3 \rangle_v = 1,
\]

where \( j_1, j_2, j_3 \in \operatorname{Rep} G \) are on the three edges meeting at the vertex \( v = 1 \) in \( \Gamma \), and

\[
B_p |j_1', j_2', j_3', j_4', j_5', j_6' \rangle_p = 1 \sum_{k \in \operatorname{Rep} G} |k \cdot j_1', k \cdot j_2', k \cdot j_3', k \cdot j_4', k \cdot j_5', k \cdot j_6' \rangle_p = 2,
\]

where the \( j' \)s are graced on the six edges outlining the plaquette \( p = 2 \) on \( \Gamma \).

On the other hand, we can draw the dual lattice \( \Lambda^* \) (figure 3(b)) of \( \Gamma \) and place an element of \( \operatorname{Rep} G \) on each edge of \( \Gamma^* \). Since \( \operatorname{Rep} G \cong G \), \( \mathcal{H}_\Gamma \cong \mathcal{H}_\Gamma^* \). The dual QD model with \( \operatorname{Rep} G \) is naturally defined on \( \Gamma^* \). The basis states \( |j_1, j_2, j_3 \rangle_v = 1 \) and \( |j_1', j_2', j_3', j_4', j_5', j_6' \rangle_p = 2 \) on \( \Gamma \) are the same as the basis states \( |j_1, j_2, j_3 \rangle_{p^*} = 1 \) and \( |j_1', j_2', j_3', j_4', j_5', j_6' \rangle_{v^*} = 2 \) on \( \Gamma^* \). Hence, we have

\[
B_p^* |j_1, j_2, j_3 \rangle_{p^*} = \delta_{j_1, j_2, j_3, 0} |j_1, j_2, j_3 \rangle_{p^*} = 1,
\]

\[
A_v^* |j_1', j_2', j_3', j_4', j_5', j_6' \rangle_{v^*} = 1 \sum_{k \in \operatorname{Rep} G} |k \cdot j_1', k \cdot j_2', k \cdot j_3', k \cdot j_4', k \cdot j_5', k \cdot j_6' \rangle_{v^*} = 2,
\]

\[\text{Figure 3.} \text{ A closed trivalent graph } \Gamma \text{ (a) and its dual graph } \Gamma^* \text{ (b). A vertex } v \text{ (a plaquette } p \text{) of } \Gamma \text{ becomes a plaquette } p^* \text{ (a vertex } v^* \text{) of } \Gamma^* .\]
where $B^*_p$, and $A^*_v$ are the plaquette and vertex operators of the dual QD model. Comparing eqs. (5.3) and (5.4) to (5.5) and (5.6), and since the above discussion applies to any vertex and plaquette on $\Gamma$, we conclude that the QD model with a group $G$ on $\Gamma$ is mapped to the dual QD model with a group $\text{Rep}_G$ on $\Gamma^*$, with $\mathcal{H}_\Gamma \cong \mathcal{H}_{\Gamma^*}$, and

$$A_v = B^*_p, \quad B_p = A^*_v.$$  \hspace{1cm} (5.7)

Since $A_v$ measures the gauge charges (which have an electric nature) and $B_p$ measures the gauge fluxes (which have a magnetic nature), the above duality is an electric-magnetic duality: an electric charge/magnetic flux on $\Gamma$ is mapped to a magnetic flux/electric charge on $\Gamma^*$.

For non-Abelian cases, $\text{Rep}_G$ is no longer a group. In a generalized context using quantum groups (Hopf algebra), we can still define the charges and fluxes of $\text{Rep}_G$, and thus are able to study the EM duality [6] in the QD model on a closed surface. In ref. [8], the authors have also checked the EM duality in the enlarged Hilbert space of the LW model on a closed surface.

5.2 EM duality on the boundary

Our results in sections 3 and 4 enable us to extend the EM duality in the bulk to one that is on the boundary. We again consider the Abelian cases first. As reviewed in section 2, on the boundary, given a subgroup $K$, there are two types of operators, $A_v$ acting on the boundary vertices, and $B_p$ on the boundary edges, as illustrated in figure 4(a).

$$\tilde{A}_v |g_1, g_2, g_3\rangle = \frac{1}{|K|} \sum_{k \in K} |k \cdot g_1, k \cdot g_2, k \cdot g_3\rangle,$$

$$\tilde{B}_p |g\rangle = \delta_g \in K |g\rangle.$$ \hspace{1cm} (5.8)

The $\tilde{A}_v$ measures the $K$-charges, while $\tilde{B}_p$ measures the $G/K$-fluxes.

To reveal the EM duality on the boundary, we need to extend the lattice $\Gamma$ in figure 4(a) to the lattice $\tilde{\Gamma}$ in 4(b), following the procedure illustrated in figure 2. As explained in section 3.2, this extension preserves the Hilbert space of the extended QD model, i.e., $\mathcal{H}_{\Gamma} = \mathcal{H}_{\tilde{\Gamma}}$, and is merely a basis transformation. That is, the basis of the Hilbert space is transformed from the group space to the representation space.

Then according to eqs. (2.7) and (2.8) and the basis transformation, a boundary vertex operator $\tilde{A}_v$ and plaquette operator $\tilde{B}_p$ acts respectively on the highlighted dangling edge and open plaquette on $\tilde{\Gamma}$ in figure 4(b) as

$$\tilde{A}_v |j\rangle_v = \delta_{j \in L_{A}} |j\rangle_v,$$

$$\tilde{B}_p |j_1, j_2, j_3, j_4\rangle_p = \frac{1}{|L_{A}|} \sum_{i \in L_{A}} |i \cdot j_1, i \cdot j_2, i \cdot j_3, i \cdot j_4\rangle_p,$$ \hspace{1cm} (5.10)

where $j \in \text{Rep}_G$ is graced on the red dangling edge in figure 4(b), and

$$\tilde{B}_p |j_1, j_2, j_3, j_4\rangle_p = \frac{1}{|L_{A}|} \sum_{i \in L_{A}} |i \cdot j_1, i \cdot j_2, i \cdot j_3, i \cdot j_4\rangle_p,$$ \hspace{1cm} (5.11)
Figure 4. (a) a trivalent lattice $\Gamma$ with a boundary, (b) its extension $\tilde{\Gamma}$, and (c) the dual lattice $\tilde{\Gamma}^*$ of $\tilde{\Gamma}$. Bulk is in grey and to the left of the boundary. In the extended lattice $\tilde{\Gamma}$, the dangling edges in the bulk (see figure 2(d)) are neglected because we focus on the boundary. A boundary vertex (edge) in $\Gamma$ is highlighted in red (blue). A boundary vertex (edge) in $\Gamma$ becomes a dangling edge (open plaquette with four edges) in $\tilde{\Gamma}$ and then becomes a boundary edge (a four-valent boundary vertex) on $\tilde{\Gamma}^*$.

where $j_1, j_2, j_3, j_4 \in \text{Rep}_G$ are respectively placed on the four blue edges outlining the open plaquette in figure 4(b), and $L_A$ is a subgroup of $\text{Rep}_G$ defined by

$$L_A = \{ j \in \text{Rep}_G | \rho^j(k) = 1, \forall k \in K \}. \quad (5.12)$$

We then draw in figure 4(c) the dual lattice $\tilde{\Gamma}^*$ of the extended lattice $\tilde{\Gamma}$. This dual lattice $\tilde{\Gamma}^*$ is a triangular lattice with a boundary and naturally defines a dual extended QD model with $\text{Rep}_G$ being the gauge group. The dual boundary operators $\overline{B}^*_{p*}$ and $\overline{A}^*_v$, act on the dual boundary edges and vertices as

$$\overline{B}^*_{p*}|j\rangle_{p*} = \delta_{j \in L_A}|j\rangle, \quad (5.13)$$

$$\overline{A}^*_v |j_1, j_2, j_3, j_4\rangle_{v*} = \frac{1}{|L_A|} \sum_{i \in L_A} |i \cdot j_1, i \cdot j_2, i \cdot j_3, i \cdot j_4\rangle_{v*}. \quad (5.14)$$

Comparing eqs. (5.10) and (5.11) to (5.13) and (5.14), we conclude that the extended QD model with a group $G$ on $\Gamma$ is mapped to the dual extended QD model with the group $\text{Rep}_G$ on $\tilde{\Gamma}^*$, with $\mathcal{H}_G \cong \mathcal{H}_{\tilde{\Gamma}^*}$, and

$$\overline{A}_v = \overline{B}^*_{p*}, \overline{B}_p = \overline{A}^*_v. \quad (5.15)$$

The $\overline{A}_v$ measuring $K$-charges is mapped to $\overline{B}^*_{p*}$ measuring $(\text{Rep}_G/L_A)$-fluxes, and $\overline{B}_p$ measuring $G/K$-fluxes to $\overline{A}^*_v$ measuring $L_A$-charges. Although we consider the Abelian examples here, the duality (5.15) can be examined for an arbitrary finite group, in the language of Frobenius algebras. After the Fourier transformation, eqs. (5.10) and (5.11) become eqs. (3.28) and (3.32), expressed in terms of the Frobenius algebra $A$. They can be viewed as the operators that measure the $(\text{Rep}_G/L_A)$-fluxes and $L_A$-charges in a more generalized context.
Figure 5. A portion of the lattice $\tilde{\Gamma}$ on which the basis states of the Fourier-transformed Hilbert space. See also figure 2(d) for reminiscence.

6 Mapping the Fourier-transformed extended QD model to the extended LW model

The Fourier-transformed extended QD model with a finite gauge group $G$ can actually be regarded as an extended LW model with an input unitary fusion category whose simple objects are the irreducible representations of $G$, commonly denoted by $\text{Rep}_G$. According to the results of section 3, the Fourier-transformed Hilbert space of the extended QD model is spanned by the basis states defined on a trivalent lattice $\tilde{\Gamma}$, each vertex of which has an associated dangling edge, as shown in figure 5. We have denoted by $L_G$ the set of all irreducible representations of $G$. Each edge (an internal one or dangling one) of the lattice carries an element of $L_G$. The open end of each dangling edge also carries an extra degree of freedom ($\tilde{m}_{s_i}$ or $\tilde{m}_{q_i}$ in the figure), which is analogously the $z$-component of the irreducible representation on the edge ($s_i$ or $q_i$ in the figure). Note that as defined in eq. (3.28), here we choose the indices $\tilde{m}_{s_i}$ and $\tilde{m}_{q_i}$ that diagonalize the vertex operators $A_v$ and $\overline{A}_v$.

The original LW model [2] is known to have a Hilbert space smaller than that of the QD model [7] because the Hilbert space of the original LW model does not contain excited states with charges or dyons [8]. In ref. [8], the authors enlarged the original LW model by adding a tail to each vertex in the trivalent lattice of the model. The enlarged LW model has a larger Hilbert space encompassing a full dyon spectrum due to the tails, which play the same role as the dangling edges in figure 5. Therefore, to map the Fourier-transformed extended QD model to the extended LW model with an enlarged Hilbert space, there is no need of reducing the Hilbert space of the extended QD model, in contrary to what was done in ref. [7].

What acts on the basis states in figure 5 is the Fourier transformed version of the Hamiltonian of the extended QD model. Namely,

$$H_{L_G,A_G,K}^{\text{QD,}\tilde{\Gamma}} = \tilde{H}_{G,K}^{\text{QD,}\tilde{\Gamma}} = - \sum_{v \in \tilde{\Gamma} \setminus \partial \tilde{\Gamma}} A_v^{\text{QD}} + \sum_{p \in \Gamma \setminus \partial \Gamma} B_p^{\text{QD}} - \sum_{v \in \partial \tilde{\Gamma}} A_v^{\overline{\text{QD}}} - \sum_{p \in \partial \Gamma} B_p^{\overline{\text{QD}}} .$$

(6.1)
In eqs. (3.28) and (3.31), we have already obtained the action of $\tilde{A}_v^{\text{QD}}$ on boundary vertices and that of $\tilde{B}_p^{\text{QD}}$ on boundary plaquettes in the lattice states in figure 5. To see how the bulk vertex operators $A_v^{\text{QD}}$ on the lattice states in figure 5, note that according to section 3.3, the action of $A_v^{\text{QD}}$ is the same as that of $\tilde{A}_v^{\text{QD}}$ when $K = G$. Hence, by eq. (3.28), we have

$$A_v^{\text{QD}}|\Psi_{s m s}\rangle = P_s^s|\Psi_{s m s}\rangle = \delta_{s,0}|\Psi_{s m s}\rangle,$$

(6.2)

where use is made of $P_s^s = \frac{1}{|G|} \sum_g D_{m s}^{s, s}(g) = \delta_{s,0}$, with 0 being the trivial representation of $G$. Clearly, when $s = 0$, $m_s$ is not a degree of freedom and can be omitted. As to a bulk $B_Q^{\text{QD}}$ operator, its action on a bulk plaquette would be straightforwardly obtained and would be similar to that of the boundary $\tilde{B}_p^{\text{QD}}$ but with seven more $6j$-symbols because a bulk plaquette has seven more vertices on its perimeter. Besides, there is no restriction to $L_A$ in a bulk $\tilde{B}_p^{\text{QD}}$ operator.

By comparing to the boundary vertex and plaquette operators in the extended LW model reviewed in appendix B or in refs. [11, 12] and the bulk operators in the enlarged LW model in ref. [8], we can actually identify the model $H^{\text{QD}, \tilde{\Gamma}}_{G,A}$ defined on $\tilde{\Gamma}$ as the extended LW model $H^{\text{LW}, \tilde{\Gamma}}_{\text{Rep}_G,A}$ with $A = A_{G,K}$ defined on the same lattice $\tilde{\Gamma}$. That is,

$$H^{\text{QD}, \tilde{\Gamma}}_{G,A} \xrightarrow{\text{FT & basis rewriting}} H^{\text{LW}, \tilde{\Gamma}}_{\text{Rep}_G,A} \quad A = A_{G,K}.$$  

(6.3)

The two models have the same Hilbert space and Hamiltonians term by term.

7 Examples

In this section we offer two explicit examples, one for $G$ being Abelian and one for $G = S_3$, to aid the understanding of the results.

7.1 Abelian groups

Since an Abelian group is always isomorphic to the product of cyclic groups, let us consider for example $G = \mathbb{Z}_{N_1} \times \mathbb{Z}_{N_2} \ldots$. The group elements are denoted by tuples $g = (g_1, g_2, \ldots)$ with $g_1 = 0, 1, \ldots N_1 - 1$, $g_2 = 0, 1, \ldots N_2 - 1, \ldots$ All the irreducible representations of $G$ are 1-dimensional; they form a set $L = \{ (\mu_1, \mu_2, \ldots) \colon \mu_1 = 0, 1, 2, \ldots N_1 - 1, \mu_2 = 0, 1, 2, \ldots N_2 - 1, \ldots \}$. We denote element $(\mu_1, \mu_2, \ldots)$ in the set for short by $\mu$. The 3$j$-symbols are simply $w_{\mu \nu \lambda} = \delta_{\mu \nu \lambda}$, which are 1 iff $\mu + \nu + \lambda = 0 \mod N_l$ for all $l$ in $\mu$. The dual irreducible representations are defined by $\nu = \mu^* \iff \nu_l + \mu_l = 0 \mod N_l$ for all $l$ in $\mu$.

Since the irreducible representations are 1-dimensional, the representation matrices are merely complex numbers; hence, all the matrix indices can be removed. The Fourier transform of the local group-basis states on an edge takes the simple form:

$$|\mu\rangle = \frac{1}{|G|} \sum_{g \in G} D^\mu(g) |g\rangle,$$

(7.1)
Then, as in eq. (3.28), we define
\[ G \]
the multiplication of group elements. Indeed, for an Abelian group \( G \), \( \text{Rep}_G \) has a group structure and is isomorphic to \( G \) itself. This fact results in the self duality under Fourier transforming the extended QD model with an Abelian gauge group \( G \). This self duality is actually the EM-duality in eq. (5.15).

To elucidate the self duality in this example, let us study how an \( \widetilde{A}_v^{\text{QD}} \) and \( \widetilde{B}_p^{\text{QD}} \) act in the rep-basis. Following eq. (3.27), we have
\[
\widetilde{A}_v^{\text{QD}} |\Psi_s\rangle = \sum_{g,h,l \in G} \sum_{\mu',\nu',\gamma'} |\Psi_{s'}\rangle \langle \Psi_{s'}| \widetilde{A}_v^{\text{QD}} |g,h,l\rangle \langle g,h,l| \Psi_s\rangle
\]
\[ = \sum_{\mu',\nu',\gamma'} |\Psi_{s'}\rangle \langle \Psi_{s'}| \sum_{g,h,l \in G} \sum_{k \in K} \frac{1}{|K|} |kg, kh, lk\rangle \langle g, h, l| \Psi_{s_m}\rangle \]
\[ = \frac{1}{|K|} \sum_{k \in K} D^s(k) |\Psi_s\rangle = \frac{1}{|K|} \sum_{k \in K} e^{2\pi i \left( \frac{s_1 k_1}{N_1} + \frac{s_2 k_2}{N_2} + \ldots \right)} |\Psi_s\rangle. \]

As in eq. (3.28), we define
\[
\delta_{s \in L_A} := \frac{1}{|K|} \sum_{k \in K} e^{2\pi i \left( \frac{s_1 k_1}{N_1} + \frac{s_2 k_2}{N_2} + \ldots \right)}. \]

Then, following eq. (3.31), we have
\[
\langle \Psi_{s'}^{\mu',\nu',\gamma'} | \widetilde{B}_p^{\text{QD}} | \Psi_{s}^{\mu,\nu,\gamma} \rangle
\]
\[ = \sum_{g,h,l,x,y} \langle \Psi_{s'}^{\mu',\nu',\gamma'} | \widetilde{B}_p^{\text{QD}} | g, h, l, x, y\rangle \langle g, h, l, x, y| \Psi_{s}^{\mu,\nu,\gamma} \rangle
\]
\[ = \sum_{g,h,l,x,y} \sum_{t \in L_A} \frac{|K|}{|G|} D^s(t) \langle \Psi_{s'}^{\mu',\nu',\gamma'} | g, h, l, x, y\rangle \langle g, h, l, x, y| \Psi_{s}^{\mu,\nu,\gamma} \rangle
\]
\[ = \sum_{t \in L_A} \frac{|K|}{|G|} \delta_{t \cdot s',s} \delta_{t \cdot r, r} \delta_{r \cdot t, r} \delta_{r \cdot r, r} \delta_{r \cdot r, r} \delta_{r \cdot r, r} \delta_{t \cdot r, r} \delta_{t \cdot r, r} \delta_{t \cdot r, r} \delta_{t \cdot r, r} \delta_{t \cdot r, r} \delta_{t \cdot r, r}. \]

This result can be understood in the following way. Since \( G \cong \text{Rep}_G \) in this case, the constraint \( \delta_{t \cdot s',s} = 1 \) indicates the equality \( s' = s \cdot t^s \), where the dot is the group multiplication. Then, a \( \widetilde{B}_p^{\text{QD}} \) acts on its local basis states as
\[
\widetilde{B}_p^{\text{QD}} | \Psi_{s}^{\mu,\nu,\gamma} \rangle = \sum_{t \in L_A} \frac{|K|}{|G|} \delta_{t \cdot s',s} \delta_{t \cdot r, r} \delta_{r \cdot t, r} \delta_{r \cdot r, r} \delta_{r \cdot r, r} \delta_{r \cdot r, r} \delta_{t \cdot r, r} \delta_{t \cdot r, r} \delta_{t \cdot r, r} \delta_{t \cdot r, r} \delta_{t \cdot r, r} \delta_{t \cdot r, r} | \Psi_{t \cdot s',t^s}^{\lambda,\eta,\theta} \rangle,
\]
\[ = \sum_{t \in L_A} \frac{|K|}{|G|} | \Psi_{t \cdot s',t^s}^{\lambda,\eta,\theta} \rangle, \quad (7.6) \]
where we omit the delta functions that are implied in the definition of $|\Psi_{r,s}\rangle$. (All vertices in figure in eq. (3.30) must satisfy the fusion rule.) The results here exemplify the EM-duality in eq. (5.15). That is, the operators $\bar{A}_v^{QD}$ in the rep-basis act on $\hat{\Gamma}$ as the operators $\bar{B}_p^{QD}$ in the corresponding group-basis act on the dual lattice $\hat{\Gamma}^*$, while the operators $\hat{B}_p^{QD}$ in the rep-basis act on $\hat{\Gamma}$ as the operators $\hat{A}_v^{QD}$ in the group-basis act on $\hat{\Gamma}^*$.

On the other hand, $\text{Rep}_G$ has the $6j$ symbols $G_{\gamma\rho\delta}^{\mu\nu\lambda} = \delta_{\mu\nu} \delta_{\lambda\rho} \lambda \cdot \delta_{\nu\rho} \rho \cdot \delta_{\mu\rho} \rho \cdot$ and Frobenius algebra multiplication rule $f_{abc} = \delta_{abc}$. Take $\text{Rep}_G$ as the input data of the extended LW model and compare it with the boundary operator actions (3.27) and (3.31), one can see that the Fourier-transformed boundary Hamiltonian with $K \subseteq G$ of the extended QD model is exactly the same as the boundary Hamiltonian with $A_{G,K}$ of the extended LW model.

Finally, we study eq. (7.4) more explicitly. Let us consider in particular $G = \mathbb{Z}_m$ with a subgroup $K = \mathbb{Z}_n$, such that $n|m$. The subgroup elements are labeled by a set of integers \( \{0, \frac{m}{n}, \frac{2m}{n}, \ldots, \frac{m(n-1)}{n}\} \). According to eq. (7.4), we have $\delta_{\delta \in \langle s \rangle} = \frac{1}{n} \left(1 + e^{2\pi i \frac{s}{n}} + e^{4\pi i \frac{2s}{n}} + \cdots + e^{2\pi i \frac{(n-1)s}{n}} \right)$\( = \frac{1}{n} \frac{1 - e^{2\pi is}}{1 - e^{2\pi i/n}} \). Thus, only when $s = jn$, $j \in \mathbb{N}$, we have $\delta_{\delta \in \langle s \rangle} = 1$; hence, $L_A = \{0, n, 2n, \ldots, m - n\}$, and $A_{\mathbb{Z}_m, \mathbb{Z}_n} = (L_A, \delta_{abc}) \cong \mathbb{Z}_{m/n}$. Clearly, the larger (smaller) the $\mathbb{Z}_n$, the smaller (larger) the $A_{\mathbb{Z}_m, \mathbb{Z}_n}$. Since $n|m$, $\mathbb{Z}_n$ is a normal subgroup of $\mathbb{Z}_m$, and $\mathbb{Z}_{m/n} = \mathbb{Z}_m/\mathbb{Z}_n$. This is a special case of the general EM duality $A_{G,K} = (\mathbb{C}[G]/\mathbb{C}[K])^*$ on the boundary of the extended QD model.

### 7.2 $G = S_3$

When $G = S_3$, the output of the extended QD model is a topological phase described by $D(S_3)$, the quantum double of $S_3$. The anyons carry representations of $([c], \mu)$ of $D(S_3)$, where $[c]$ is a conjugacy class in $S_3$, and $\mu$ is an irreducible representation of the centralizer of $[c]$ in $S_3$. Thus, the anyons can be divided into three types: $S_3$ charges, fluxes, and dyons, as shown in table 2.

For notation simplicity, we rename the three irreducible representations of $S_3$ by 0, 1, and 2, respectively corresponding to the 1, $\text{sign}$, and $\pi$ in the table above. One set of

| Anyon types | $A, B, C$ | $D, E$ | $F, G, H$ |
|-------------|-----------|-------|-----------|
| Conjugacy classes | $\{e\}$ | $\{s, rs, r^2s\}$ | $\{r, r^2\}$ |
| Centralizer | $S_3$ | $\mathbb{Z}_2$ | $\mathbb{Z}_3$ |
| Irrep of centralizer | 1, $\text{sign}$, $\pi$ | 1, $-1$ | 1, $\omega$, $\omega^*$ |
| Quantum dimension | 1, 1, 2 | 3, 3 | 2, 2, 2 |
| Twist | 1, 1, 1 | 1, $-1$ | $1, e^{2\pi i/3}, e^{-2\pi i/3}$ |

### Table 2. Information of anyons of the $D(S_3)$ model. Anyons of types $A, B$, and $C$ are pure charges, $D$ and $E$ are pure fluxes, and $F, G, H$ are dyons.
irreducible representations matrices is listed as follows.

\[
\begin{align*}
D^0(e) &= D^0(r) = D^0(r^2) = D^0(sr) = D^0(s) = D^0(sr^2) = 1, \\
D^1(e) &= D^1(r) = D^1(r^2) = 1, \\
D^2_{m_2m_2'}(e) &= \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix}_{m_2m_2'}, \\
D^2_{m_2m_2'}(r) &= \begin{pmatrix} -\frac{1}{2} & -\frac{\sqrt{3}}{2} \\ \frac{\sqrt{3}}{2} & -\frac{1}{2} \end{pmatrix}_{m_2m_2'}, \\
D^2_{m_2m_2'}(r^2) &= \begin{pmatrix} -\frac{1}{2} & -\frac{\sqrt{3}}{2} \\ \frac{\sqrt{3}}{2} & -\frac{1}{2} \end{pmatrix}_{m_2m_2'}, \\
D^2_{m_2m_2'}(s) &= \begin{pmatrix} -1 & 0 \\ 0 & 1 \end{pmatrix}_{m_2m_2'}, \\
D^2_{m_2m_2'}(sr) &= \begin{pmatrix} \frac{1}{2} & -\frac{\sqrt{3}}{2} \\ \frac{\sqrt{3}}{2} & -\frac{1}{2} \end{pmatrix}_{m_2m_2'}, \\
D^2_{m_2m_2'}(sr^2) &= \begin{pmatrix} \frac{1}{2} & -\frac{\sqrt{3}}{2} \\ \frac{\sqrt{3}}{2} & -\frac{1}{2} \end{pmatrix}_{m_2m_2'}.
\end{align*}
\] (7.7)

The nonvanishing 3j-symbols of \( S_3 \) are

\[
\begin{align*}
&u_{111}^{000} = u_{111}^{011} = 1, \\
u_{1m_1m_2}^{022} = \begin{pmatrix} \frac{1}{2} & 0 \\ 0 & 1 \end{pmatrix}_{m_1m_2}, \\
u_{1m_1m_2}^{122} = \begin{pmatrix} 0 & \frac{i}{\sqrt{2}} \\ -\frac{i}{\sqrt{2}} & 0 \end{pmatrix}_{m_1m_2}, \\
u_{m_1m_2m_3}^{222} = \begin{pmatrix} 0, \frac{1}{2} \\ \frac{1}{2}, 0 \end{pmatrix}_{m_1m_2m_3}, \\
u_{m_1m_2m_3}^{222} = \begin{pmatrix} \{0, \frac{1}{2}\} \\ \{\frac{1}{2}, 0\} \end{pmatrix}_{m_1m_2m_3}.
\end{align*}
\] (7.8)

Plugging the 3j-symbols (7.8) into eq. (3.33), we can obtain four emergent Frobenius algebras at the boundary of the Fourier-transformed extended QD model, corresponding to the four distinct subgroups of \( S_3 \), as recorded in table 3. The four emergent Frobenius algebras can indeed be identified with the four Frobenius algebra objects in table 4 obtained by solving the defining conditions (4.1) of a Frobenius algebra object in a UFC \( \mathfrak{F} \), which in this case is \( \text{Rep}_{S_3} \).
Frobenius algebra (modulo Morita equivalence) objects in $\text{Rep}_{S_3}$

\[
\begin{align*}
    f_{abc} &= f_{cab}, \\
    f_{a00} &= 1
\end{align*}
\]

\[
\begin{align*}
    A_1 &= 0 \text{ (Morita equivalent to } A_1' = \oplus 1 \oplus 2, f_{122} = \pm 1) \\
    A_2 &= 0 \oplus 1 \\
    A_3 &= 0 \oplus 2, f_{222} = 2^{-i} \\
    A_4 &= 0 \oplus 1 \oplus 2 \oplus 2, f_{110} = 1, f_{212} = -i, f_{222} = 2^{-i} 
\end{align*}
\]

**Table 4.** Inequivalent Frobenius algebra objects in the UFC $\text{Rep}_{S_3}$ obtained by solving the defining conditions (4.1). Frobenius algebra objects $A_1 = 0$ and $A_1' = \oplus 1 \oplus 2$ are Morita equivalent [12]. One thus can forget about $A_1'$.

| Condensation type | Boundary condensate | Boundary $A_{S_3,K}$ | Boundary $K$ |
|-------------------|---------------------|----------------------|--------------|
| Charge            | $A_1 = A \oplus F \oplus D$ | $A_1$ | $S_3$ |
| Dyon              | $A_2 = A \oplus B \oplus 2F$ | $A_2$ | $\mathbb{Z}_3$ |
| Dyon              | $A_3 = A \oplus C \oplus D$ | $A_3$ | $\mathbb{Z}_2$ |
| Flux              | $A_4 = A \oplus B \oplus 2C$ | $A_4$ | $\{e\}$ |

**Table 5.** Correspondence between (column 1) anyon condensates of the $D(S_3)$ model, emergent Frobenius algebras (column 2), and subgroups of $S_3$ (column 3).

Here we can try to understand explicitly the relation between the emergent Frobenius algebras at the boundary and anyon condensation, in particular anyon splitting and multiplicity.

In the current example, there are four different gapped boundary conditions respectively characterized by the four subgroups\(^1\) of $S_3$, imposed by the boundary plaquette operators $B^\text{QD}_p$ of the model. These four gapped boundary conditions respectively correspond to four different boundary condensates composed of different types of anyons condensed at the boundary. These correspondences are shown in table 5. One can see in the table that the type C anyons, which are pure charges ([e], 2), appear with multiplicity 1 in the condensate $A_3$ but multiplicity 2 in the condensate $A_4$.

Condensate $A_3$ corresponds to the emergent Frobenius algebra $A_3 = (0, 1) + (2, 1)$. The element $s = 2$ in the pair $(2, 1)$ in $A_3$ actually is the 2-dimensional irreducible representation of $S_3$ and thus can be directly identified with the pure charge $C$ in the condensate $A_3$. Note that for each $K \subseteq S_3$ in table 3, the pairs $(s, \alpha_s)$ in the corresponding row each labels a +1 local eigenstate $|\Psi_{s\alpha_s}\rangle$ of the $A^\text{QD}_v$ operator acting on the relevant vertex. In the case with $K = \mathbb{Z}_2$ and $s = 2$, seen in eq. (3.27), an operator $A^\text{QD}_v$ is represented in the 2-dimensional local space $V_s$ by the projector

\[
P_{K=\mathbb{Z}_2}^{s=2} = \sum_{k \in \mathbb{Z}_2} \frac{1}{|\mathbb{Z}_2|} D_{m_2m'_2}^{22}(k) = \frac{1}{4} \begin{pmatrix} 3 & \sqrt{3} \\ \sqrt{3} & 1 \end{pmatrix}, \tag{7.9}
\]

\(^1\) $S_3$ actually has three $\mathbb{Z}_2$ subgroups, which however specifies the same boundary condition and corresponds to the same Frobenius algebra.
Table 6. The GSDs of the extended QD model with $G = S_3$ on a cylinder, whose two boundaries are specified by two subgroups of $S_3$.

| Subgroups | $\{e\}$ | $S_3$ | $Z_3$ | $Z_2$ |
|-----------|---------|------|------|------|
| $\{e\}$  | 6 1 2 3 |      |      |      |
| $S_3$     | 1 3 3 2 |      |      |      |
| $Z_3$     | 2 3 6 1 |      |      |      |
| $Z_2$     | 3 2 1 3 |      |      |      |

Table 7. The GSDs of the extended LW model with $\text{Rep}_{S_3}$ on a cylinder, whose boundaries are specified by two not necessarily different Frobenius algebra objects of $\text{Rep}_{S_3}$.

| Frobenius algebras | $A_4$ | $A_1$ | $A_2$ | $A_3$ |
|---------------------|------|------|------|------|
| $A_4$               | 6 1 2 3 |     |     |     |
| $A_1$               | 1 3 3 2 |     |     |     |
| $A_2$               | 2 3 6 1 |     |     |     |
| $A_3$               | 3 2 1 3 |     |     |     |

where we didn’t differentiate a matrix and its matrix elements labeled by $m_s m_s'$ to emphasize that the operator is not diagonalized yet. We can diagonalize the projector in the basis states $e_n \tilde{m}$ labeled by $\tilde{m}$ and find the $+1$ eigenstate $e_1 = (\frac{\sqrt{3}}{2}, \frac{1}{2})^T$ and $0$ eigenstate $e_2 = (-\frac{1}{2}, \frac{\sqrt{3}}{2})^T$. Hence, only $\alpha = \tilde{m} = 1$ is allowed. That is, the pair $(2, 1) \in L_A$ labels the only $+1$ local eigenstate $|\Psi_2\rangle$ of the $\tilde{A}_Q^{\text{QD}}$. Hence, only half of the 2-dimensional space $V_s$ or half of the charge-2 condenses at the boundary. As such, we can say that the charge-2 splits: $2 = (2, 1) \oplus (2, 2)$ but only the half $(2, 1)$ condenses. That is why only $(2, 1)$ appears in the $A_3$ in table 3, and type $C$ anyons appear with unit multiplicity in $A_3$ in table 5. If we denote $(2, 1)$ by $2_1$ and $(2, 2)$ by $2_2$, we found that the Frobenius algebra object $A_3$ in table 3 should be rigorously written as $A_3 = 0 \oplus 2_1$; however, one often just write $A_3 = 0 \oplus 2$ customarily.

Now in the case with $A_4$ corresponding to $A_4$, the subgroup is $K = \{e\}$. Then, for $s = 2$, an operator $\tilde{A}_Q^{\text{QD}}$ is represented in the 2-dimensional local space $V_s$ by the matrix $P_s^{K=\{e\}} = D^{s}_{m_s m'_s}(e) = \delta_{m_s m'_s} = \delta_{\tilde{m}_s \tilde{m}'_s}$, which is automatically diagonal and in fact a $2 \times 2$ identity matrix. Thus both local eigenstates of $\tilde{A}_Q^{\text{QD}}$ in $V_s$ are $+1$ eigenstates, which can be labeled by $(2, 1)$ and $(2, 2)$. Note that these two eigenstates are not those of the operator in eq. (7.9). As such, the charge 2 splits as $2 = (2, 1) \oplus (2, 2)$, but both pieces condense at the boundary. Therefore, in the boundary condensate, the type $C$ anyons count twice, rendering $A_4 = A \oplus B \oplus 2C$. If we write $(2, 1)$ and $(2, 2)$ as $2_1$ and $2_2$, we can identify the emergent Frobenius algebra $A_4$ with the Frobenius algebra object $A_4 = 0 \oplus 1 \oplus 2_1 \oplus 2_2$ in table 4.

As a further corroboration of the mapping between the extended QD model and the extended LW model, we can compute the GSDs of both models on a cylinder, whose two boundaries may not necessarily possess the same boundary conditions. Using eqs. (2.9) and (B.10), we obtain respectively table 6 and table 7.
two tables further confirms the correspondence between the gapped boundary conditions specified by the subgroups of $S_3$ in the extended QD model and those specified by the Morita inequivalent Frobenius algebra objects in the extended LW model.

For completeness of the data in this example, we collect in table 8 the Modules of the Frobenius algebras in \text{Rep}_{S_3}.

### Acknowledgments

The authors thank Perimeter Institute for hospitality during their visit, where this project was largely done and completed. We thank Zichang Huang for helpful discussions. YW is supported by the NSF grant No. 11875109.

### A Some properties of fusion categories

Simple objects in a UFC $\mathcal{F}$ obey a set of fusion rules:

$$i \otimes j = \sum_k N_{ij}^k k,$$  \hspace{1cm} (A.1)

where $N_{ij}^k$ are the fusion coefficients satisfying

$$N_{0i}^j = N_{i0}^j = \delta_{i,j},$$
$$N_{ij}^0 = \delta_{i,j^*},$$
$$\sum_m N_{ij}^m N_{mk}^l = \sum_n N_{jk}^n N_{in}^l.$$  \hspace{1cm} (A.2)

Here, $j^*$ is the dual of $j$ defined by the second row in the equation above. Each object $j$ also has a nonzero characteristic number $\tilde{d}_j$, called quantum dimension of $j$, such that $\tilde{d}_j d_{j^*} = 1$ and

$$\tilde{d}_j d_{j^*} = \sum_k N_{ij}^k \tilde{d}_k.$$  \hspace{1cm} (A.3)
In particular, $\tilde{d}_0 = 1$. Let $\beta_j = \text{sgn}(\tilde{d}_j)$, then $\beta_i \beta_j \beta_k = 1$ is satisfied if $N_{ij}^k > 0$. When $\mathfrak{F} = \text{Rep}_G$ for a finite group $G$, we have $\tilde{d}_j = \beta_j d_j$, and $\beta_j$ is identified with the FS indicator of the representation $j$ of $G$. Now we can define tetrahedral-symmetric unitary $6j$-symbols as the coefficients of the map $G : L^6 \to \mathbb{C}$ that satisfy the following conditions

\begin{align}
G^{ijm}_{kln} &= G^{mij}_{nklt}, \\
\sum_n \tilde{d}_n G^{mlq}_{kp\tau} G^{ipj}_{mn\tau} &= G^{jip}_{q\tau k \tau} G^{q\tau m \tau}_{n\tau l \tau}, \\
\sum_n \tilde{d}_n G^{mlq}_{kp\tau} G^{m\tau i \tau}_{pk\tau n} &= \delta_{ij} \delta_{mlq} \delta_{k \tau i \tau}.
\end{align}

(B.4)

**B Extended LW model**

In this section, we review the basic ingredients of extended LW model. The extended LW model is defined on an oriented trivalent lattice $\tilde{\Gamma}'$, part of which is depicted in figure 6.

The Hilbert space is spanned by all configurations of assigning of the simple objects of a UFC $\mathfrak{F}$ on the oriented edges of $\tilde{\Gamma}'$. Conventionally, we call these simple objects string types and label them by integers in $L = \{0, 1, \ldots, N\}$. Each string type $j$ has a dual $j^*$, which is also an element of $L$ and satisfies $j^{**} = j$. If we reverse the orientation of the edge and conjugate the string type $j \mapsto j^*$ associated with the edge at the same time, the state remains the same. There is always a trivial (unit) element $0 \in L$ satisfying $0^* = 0$.

The set $\{N_{ij}^k, \tilde{d}_j, G^{ijk}_{lmm}\}$ is the input data of the extended LW model, which can be derived from representation theory of a finite group or quantum group. In this work, we take the string types $\mu$ to be the irreducible representations of a finite group $G$ and label them with Greek letters. The trivial representation is $\mu = 0$. The set $L$ is identified with $L_G$ — the set of irreducible representations of $G$. The fusion coefficients $N_{\mu \nu}^\lambda$ are the numbers of trivial representations appearing in the decomposition of $\mu \otimes \nu \otimes \lambda$. In such cases, as mentioned earlier, $\tilde{d}_\mu = \beta_\mu d_\mu$ with $\beta_\mu$ the FS indicator. The dual representation $\mu^*$ of $\mu$ satisfies $\tilde{d}_{\mu^*} = \tilde{d}_\mu$. The $6j$-symbols $G^{\mu \nu \lambda}_{\kappa \lambda \gamma}$ are the same as the symmetrized Racah $6j$-symbols of $G$. Similar to the extended QD models, there are also two types of local
operators in the bulk Hamiltonian of the extended LW model, namely

\[ H_{\ell}^{\text{LW}} = - \sum_{v \in \Gamma^1} A_v^{\text{LW}} - \sum_{p \in \Gamma^1} B_p^{\text{LW}}, \tag{B.1} \]

where \( A_v^{\text{LW}} \) and \( B_p^{\text{LW}} \) are respectively the vertex and plaquette operators. The action of \( A_v^{\text{LW}} \) on a local trivalent state as

\[ A_v^{\text{LW}} \mid \mu_1 \nu_3 \nu_2 \rangle = \delta_{\mu_1\mu_2\mu_3} \mid \mu_1 \nu_3 \nu_2 \rangle, \tag{B.2} \]

where \( \delta_{\mu_1\mu_2\mu_3} \) is delta function that is equal to 1 if \( N_{\mu_1\mu_2} > 0 \) and otherwise 0. The action of \( B_p^{\text{LW}} \) is more involved and reads

\[ B_p^{\text{LW}} = \frac{1}{D} \sum_{s \in L} c_s B_p^{\text{LW}} (s), \]

\[ B_p^{\text{LW}} (s) = \sum_{\mu_1, \mu_2, \mu_3} \prod_{i=1}^{6} \bar{v}_{\mu_i} v_{\mu_i'} G_{s\mu_i \mu_i'}^{\mu_{i+1} \mu_{i+2} \mu_{i+3}} G_{s\mu_i \mu_i'}^{\mu_{i+2} \mu_{i+3} \mu_{i+4}} G_{s\mu_i \mu_i'}^{\mu_{i+3} \mu_{i+4} \mu_{i+5}} \]

\[ \times G_{s\mu_i \mu_i'}^{\mu_{i+4} \mu_{i+5} \mu_{i+6}} G_{s\mu_i \mu_i'}^{\mu_{i+5} \mu_{i+6} \mu_1} \mid \nu_3 \nu_4 \nu_5 \nu_6 \rangle. \tag{B.3} \]

The bulk Hamiltonian is exactly solvable because all the operators therein are commuting projectors.

On the boundary \( \partial \Gamma' \) however, we need an extra input data for the extended LW to be well-defined. This extra input data is the maximal Frobenius algebra object in \( \text{Rep}_G \). This maximal Frobenius algebra object can be identified with the canonical Frobenius algebra defined in eq. (4.3). But to comply with the definition of boundary vertex operators in refs. [11, 12], where the extended LW model was constructed. We rewrite this canonical Frobenius algebra as

\[ A_{\text{canonical}} = \bigoplus_{s \in \text{Irrep}_G} d_s \bigoplus_{s \alpha_s=1} s \alpha_s. \tag{B.4} \]

As in the main text, here \( d_s \) counts the multiplicity of \( s \). Note that refs. [11, 12] actually did not consider the cases with multiplicities in a Frobenius algebra and thus did not require an extra input data on the boundary. In this review, we offer a generalization to such cases. We emphasize that in an extended LW model, the boundary \( \partial \Gamma' \) consists of the dangling...
edges only. As far as boundary degrees of freedom are concerned, we regard $A_{\text{canonical}}$ as a set and allocate to each tail on the boundary an element $s\alpha_s$. The boundary Hamiltonian of the model is then defined on the boundary lattice $\partial \tilde{\Gamma}'$ by

$$H^A_{\text{LW}} = - \sum_{n \in \partial \tilde{\Gamma}'} \overline{A}_{n}^{\text{LW}} - \sum_{p \in \partial \tilde{\Gamma}'} \overline{B}_{p}^{\text{LW}}, \quad (B.5)$$

where the $A_{n}^{\text{LW}}$ operator acts on the tail $n$ on the boundary and projects it to a Frobenius algebra object $A \subseteq A_{\text{canonical}}$ of $\text{Rep}_G$:

$$\overline{A}_{n}^{\text{LW}} \left| \begin{array}{c} \nu \\ \alpha_s \\ n \\ \mu \end{array} \right> = \delta_{s\alpha_n} \delta_{n \in A} \left| \begin{array}{c} \nu \\ \alpha_s \\ n \\ \mu \end{array} \right>, \quad (B.6)$$

and $B_{p}^{\text{LW}}$ operator is a operator comprised of $B_{p}^{\text{LW}}(t)$:

$$\overline{B}_{p}^{\text{LW}} = \frac{1}{d_A} \sum_{t \in L_A} \tilde{v}_t \overline{B}_{p}^{\text{LW}}(t\alpha_t), \quad (B.7)$$

where $d_A = \sum_{t \in L_A} d_t$, and $B_{p}^{\text{LW}}(t\alpha_t)$ acts on the open boundary $p$ between two nearest neighbouring tails as:

$$\overline{B}_{p}^{\text{LW}}(t\alpha_t) \left| \begin{array}{c} \nu \\ \alpha_s \\ \gamma_s \\ \lambda_s \\ \rho_s \\ \eta_s \\ \mu \\ \lambda' \end{array} \right> = \sum_{s', \alpha', \alpha', \nu', \lambda', \rho', \eta'} f_{t^* \alpha s^* \nu s \alpha_s} f_{\tilde{\nu} \rho \tilde{\eta} \nu' \lambda' \rho' \eta'} \left| \begin{array}{c} \nu \\ \alpha_s \\ \gamma_s \\ \lambda_s \\ \rho_s \\ \eta_s \\ \mu \\ \lambda' \end{array} \right>, \quad (B.8)$$

if one of the tail $r\alpha_s$ or $s\alpha_s \notin A$, then $f_{t^* \alpha s^* \nu s \alpha_s} f_{\tilde{\nu} \rho \tilde{\eta} \nu' \lambda' \rho' \eta'} = 0$, and hence $B_{p}^{\text{LW}}(t\alpha_t) = 0$. Each $A$ specifies a gapped boundary condition. The total Hamiltonian of the extended LW model then is the sum

$$H_{A}^{\text{LW}} = H_{\delta, A}^{\text{LW}} + H_{A}^{\text{LW}}. \quad (B.9)$$

The GSD formula on a cylinder takes the form

$$\text{GSD} = \text{Tr} P^0 = \prod_{v \in \Gamma' \setminus \partial \tilde{\Gamma}'} A_{v}^{\text{LW}} \prod_{n \in \partial \tilde{\Gamma}'} \overline{A}_{n}^{\text{LW}} \prod_{p \in \Gamma' \setminus \partial \tilde{\Gamma}'} B_{p}^{\text{LW}} \prod_{p' \in \partial \tilde{\Gamma}'} \overline{B}_{p'}^{\text{LW}}. \quad (B.10)$$

Note that on a cylinder, $\partial \tilde{\Gamma}'$ contains two components, on which the operators $A_{n}^{\text{LW}}$ may project the boundary degrees of freedom into respectively two (not necessarily) different Frobenius algebras.
C Some proofs

Here, we show that eqs. (3.26) and (3.22) can lead to the correct coefficients in eq. (3.24). This derivation corroborates eqs. (3.22) to (3.26) and is a pedagogical application of our graphical tool. The inverse transformation of eq. (3.26) is

$$v_{\mu}v_{\nu}v_{\lambda}v_{\gamma}v_{s} \rightarrow \frac{\sum_{\mu, \nu, \lambda, \gamma, s} v_{\mu}v_{\nu}v_{\lambda}v_{\gamma}v_{s}}{\sqrt{|G|^3}} \left( n_{\nu}^{m_s \rightarrow \mu} \right)^* \left( n_{\gamma}^{l_s \rightarrow \nu} \right)^* |\Psi_{s m_s} \rangle. \quad (C.1)$$

Plug eq. (C.1) into eq. (3.22), we obtain

$$v_{\mu}v_{\nu}v_{\lambda}v_{\gamma}v_{s} \rightarrow \frac{\sum_{\mu, \nu, \lambda, \gamma, s} v_{\mu}v_{\nu}v_{\lambda}v_{\gamma}v_{s}}{\sqrt{|G|^3}} \left( n_{\nu}^{m_s \rightarrow \mu} \right)^* \left( n_{\gamma}^{l_s \rightarrow \nu} \right)^* |\Psi_{s m_s} \rangle. \quad (C.2)$$
We now prove that the rep-basis defined in eq. (3.25) is orthonormal and complete.

\[ \langle \Psi'_{s'm'_s} | \Psi_{s'm_s} \rangle \]

\[ = \frac{\sum_{g,h,l} \sum_{x,y,z} v_{\mu} v_{\nu} \chi_{\gamma} v_{\chi'} v_{\lambda'} v_{\gamma'} v_{\gamma'_x} v_{\gamma'_y} v_{\gamma'_z} |G|^{-3} n_{\mu'} n_{\nu'} n_{\nu''} n_{\xi'} n_{\mu''} n_{\mu'''} n_{\chi'} n_{\chi''} n_{\chi'''} n_{\gamma'} n_{\gamma''} n_{\gamma'''} n_{\lambda'} n_{\lambda''} n_{\lambda'''} n_{\gamma_x} n_{\gamma_y} n_{\gamma_z} n_{\chi_x} n_{\chi_y} n_{\chi_z} n_{\gamma'_x} n_{\gamma'_y} n_{\gamma'_z}}{d_{\mu} d_{\mu'} d_{\lambda'}} \]

\[ = \delta_{\mu,\mu'} \delta_{\nu,\nu'} \delta_{\xi,\xi'} \delta_{\lambda,\lambda'} \delta_{\gamma,\gamma'} \delta_{m_s, m_{s'}} \delta_{n_{\mu}, n_{\mu'}} \delta_{n_{\nu}, n_{\nu'}} \delta_{n_{\lambda}, n_{\lambda'}} \]

\[ = \delta_{\mu, m_s} \delta_{\nu, m_{s'}} \delta_{\xi, m_s} \delta_{\lambda, m_{s'}} \delta_{\gamma, m_s} \delta_{\gamma', m_{s'}} \delta_{\gamma'', m_s} \delta_{\gamma''', m_{s'}} \delta_{\lambda', m_{s'}} \delta_{\lambda'', m_{s'}} \delta_{\chi, m_s} \delta_{\chi', m_{s'}} \delta_{\chi'', m_s} \delta_{\chi''', m_{s'}} \delta_{\gamma_x, m_s} \delta_{\gamma_y, m_{s'}} \delta_{\gamma_z, m_s} \delta_{\gamma'_x, m_{s'}} \delta_{\gamma'_y, m_{s'}} \delta_{\gamma'_z, m_{s'}} \]

\[ = \delta_{\mu, m_s} \delta_{\nu, m_{s'}} \delta_{\xi, m_s} \delta_{\lambda, m_{s'}} \delta_{\gamma, m_s} \delta_{\gamma', m_{s'}} \delta_{\gamma'', m_s} \delta_{\gamma''', m_{s'}} \delta_{\lambda', m_{s'}} \delta_{\lambda'', m_{s'}} \delta_{\chi, m_s} \delta_{\chi', m_{s'}} \delta_{\chi'', m_s} \delta_{\chi''', m_{s'}} \delta_{\gamma_x, m_s} \delta_{\gamma_y, m_{s'}} \delta_{\gamma_z, m_s} \delta_{\gamma'_x, m_{s'}} \delta_{\gamma'_y, m_{s'}} \delta_{\gamma'_z, m_{s'}} \]
where the second line uses eq. (3.25) and last equality uses eq. (3.17). To prove the completeness, we check that

\[
\sum_{\mu,\nu,\gamma} \sum_{g,h,l} \sum_{s,m} |g, h, l\rangle \langle g, h, l| \Psi_{sm_s} \langle \Psi_{sm_s} | x, y, z \rangle \langle x, y, z |
\]

\[
= \sum_{\mu,\nu,\gamma} \sum_{g,h,l} \sum_{s,m} \frac{d_\mu d_\nu d_\lambda d_\gamma}{|G|^3} |g, h, l\rangle \langle x, y, z | n_\mu n_\nu n_\lambda
\]

\[
= \sum_{\mu,\nu,\gamma} \sum_{g,h,l} \sum_{s,m} \frac{d_\mu d_\nu d_\lambda d_\gamma}{|G|^3} |g, h, l\rangle \langle x, y, z | n_\mu n_\nu n_\lambda
\]

\[
= \sum_{\mu,\nu,\gamma} \sum_{g,h,l} \sum_{s,m} \frac{d_\mu d_\nu d_\lambda d_\gamma}{|G|^3} |g, h, l\rangle \langle x, y, z | n_\mu n_\nu n_\lambda
\]
where use is made of the great orthogonality theorem \((3.6)\)

\[
\sum_{\mu} \frac{d_{\mu}}{|G|} \delta_{\mu, \mu'} = \delta_{\mu, \mu'}, \quad \sum_{\mu} \frac{d_{\mu}}{|G|} \delta_{\mu, \mu'} = \delta_{\mu, \mu'}. \tag{C.4}
\]

Thus, the rep-basis is orthonormal and complete.

Details of the action of the operators \(\overrightarrow{A}_{\nu}^{D} \) in rep-basis are as follows.

\[
\overrightarrow{A}_{\nu}^{D} |\Psi_{m_{s}}\rangle = \sum_{\mu, m_{s}'} \sum_{g, h, l \in G} \sum_{k, \lambda, \mu, \mu', \gamma, \gamma'} \sum_{n_{\nu}, n_{\nu}', s, m_{s}} \sum_{n_{\mu}, n_{\mu}', s, m_{s}} \sum_{n_{\nu}, n_{\nu}', s, m_{s}} \frac{1}{|K|} |\Psi_{m_{s}}\rangle |\Psi_{m_{s}}\rangle |\Psi_{k, \lambda, \mu, \mu', \gamma, \gamma'}\rangle |\Psi_{n_{\nu}, n_{\nu}', s, m_{s}}\rangle |\Psi_{n_{\mu}, n_{\mu}', s, m_{s}}\rangle |\Psi_{n_{\nu}, n_{\nu}', s, m_{s}}\rangle.
\]

\[
\overrightarrow{A}_{\nu}^{D} |\Psi_{m_{s}}\rangle = \sum_{\mu, m_{s}'} \sum_{g, h, l \in G} \sum_{k, \lambda, \mu, \mu', \gamma, \gamma'} \sum_{n_{\nu}, n_{\nu}', s, m_{s}} \sum_{n_{\mu}, n_{\mu}', s, m_{s}} \sum_{n_{\nu}, n_{\nu}', s, m_{s}} \frac{1}{|K|} |\Psi_{m_{s}}\rangle |\Psi_{m_{s}}\rangle |\Psi_{k, \lambda, \mu, \mu', \gamma, \gamma'}\rangle |\Psi_{n_{\nu}, n_{\nu}', s, m_{s}}\rangle |\Psi_{n_{\mu}, n_{\mu}', s, m_{s}}\rangle |\Psi_{n_{\nu}, n_{\nu}', s, m_{s}}\rangle.
\]

\[
\overrightarrow{A}_{\nu}^{D} |\Psi_{m_{s}}\rangle = \sum_{\mu, m_{s}'} \sum_{g, h, l \in G} \sum_{k, \lambda, \mu, \mu', \gamma, \gamma'} \sum_{n_{\nu}, n_{\nu}', s, m_{s}} \sum_{n_{\mu}, n_{\mu}', s, m_{s}} \sum_{n_{\nu}, n_{\nu}', s, m_{s}} \frac{1}{|K|} |\Psi_{m_{s}}\rangle |\Psi_{m_{s}}\rangle |\Psi_{k, \lambda, \mu, \mu', \gamma, \gamma'}\rangle |\Psi_{n_{\nu}, n_{\nu}', s, m_{s}}\rangle |\Psi_{n_{\mu}, n_{\mu}', s, m_{s}}\rangle |\Psi_{n_{\nu}, n_{\nu}', s, m_{s}}\rangle.
\]
Detailed action of the operators $\overrightarrow{B}^{\text{QD}}_p$ in the rep-basis reads as follows

$$
\langle \Psi^{\nu' X'}_{r', m_{r'}; s', \bar{m}_{s'}} | \overrightarrow{B}^{\text{QD}}_p | \Psi^{\nu \lambda}_{r m_r; s \bar{m}_s} \rangle
= \sum_{g, h, l, x, y} \langle \Psi^{\nu' X'}_{r', m_{r'}; s', \bar{m}_{s'}} | \overrightarrow{B}^{\text{QD}}_p | g, h, l, x, y \rangle \langle g, h, l, x, y | \Psi^{\nu \lambda}_{r m_r; s \bar{m}_s} \rangle
$$

$$
= \sum_{g, h, l, x, y} \sum_{(t, \alpha_t) \in L_A} \frac{|K|}{G} d_t D^f(l)_{\alpha t \alpha_t} \langle \Psi^{\nu' X'}_{r', m_{r'}; s', \bar{m}_{s'}} | g, h, l, x, y \rangle \langle g, h, l, x, y | \Psi^{\nu \lambda}_{r m_r; s \bar{m}_s} \rangle
$$

$$
= \sum_{g, h, l, x, y} \sum_{(t, \alpha_t) \in L_A} \frac{|K|}{G} d_t \left( \frac{G}{|G|^5} \right) \langle \Psi^{\nu' X'}_{r', m_{r'}; s', \bar{m}_{s'}} | g, h, l, x, y \rangle \langle g, h, l, x, y | \Psi^{\nu \lambda}_{r m_r; s \bar{m}_s} \rangle
$$

$$
= \sum_{g, h, l, x, y} \sum_{(t, \alpha_t) \in L_A} \frac{|K|}{G} \frac{G}{|G|^8} d_t
$$

$$
= \sum_{g, h, x, y; d_1, d_2, d_3, d_4} \frac{|K|}{|G|^8} \frac{G}{|G|^5} d_t
$$
\[

n_{0'} \\
\rho' \\
\gamma' \\
\mu' \\
n_{a'} \\
\mu' \\
n_{0'} \\
\rho' \\
\gamma' \\
\mu' \\
n_{a'} \\
\end{array} \right) 
= \sum_{g', h', x', y', l_1, l_2, l_3, l_4 (t, \alpha_t) \in L_A} \frac{|K| v_{\eta} v_{\rho} v_{\gamma} v_{\mu} v_{\eta'} v_{\rho'} v_{\gamma'} v_{\mu'} d_{\mu} d_{\rho} d_{\gamma} d_{\mu'} d_{\rho'} d_{\gamma'} d_{l} d_{t}}{|G|^4} d_t 
\]

\[
\left( \begin{array}{c}
\eta \\
n_0 \\
\rho \\
\gamma \\
\mu \\
n_a \\
\mu \\
n_0 \\
\rho \\
\gamma \\
\mu \\
n_a \\
\end{array} \right) \times \left( \begin{array}{c}
\eta' \\
n_{0'} \\
\rho' \\
\gamma' \\
\mu' \\
n_{a'} \\
\mu' \\
n_{0'} \\
\rho' \\
\gamma' \\
\mu' \\
n_{a'} \\
\end{array} \right) 
= \sum_{l_1, l_2, l_3, l_4 (t, \alpha_t) \in L_A} \frac{|K| v_{\eta} v_{\rho} v_{\gamma} v_{\mu} v_{\eta'} v_{\rho'} v_{\gamma'} v_{\mu'} d_{\mu} d_{\rho} d_{\gamma} d_{\mu'} d_{\rho'} d_{\gamma'} d_{l} d_{t}}{|G|^4} d_t 
\]
great orthogonality theorem, we have

\[ \sum_{(t, \alpha_t) \in L_A} \frac{|K|}{|G|} \beta_s^t \beta_{s'} \beta_{s''} \beta_{s'''} dt v \eta_1 v \eta_2 v \lambda v \eta' v \lambda' v \eta'' v \lambda'' v \eta''' v \lambda''' \],

(C.6)

\[ = \sum_{(t, \alpha_t) \in L_A} \sum_{\tilde{n}_r, \tilde{n}_{s'}, \tilde{n}_{s''}} \frac{1}{d_A} d_t v_{\eta_1} v_{\eta_2} v_{\lambda} v_{\eta'} v_{\lambda'} v_{\eta''} v_{\lambda''} (w_{\tilde{n}_r, \alpha_t, \tilde{n}_r, \tilde{n}_{s'}})^{t} (\Omega^t)^{-1}_{\tilde{n}_r, \tilde{n}_r} \]

\[ \times (w_{\tilde{n}_{s'}, \tilde{n}_{s''}, \tilde{n}_{s'''}})^{t} (\Omega^{s'})^{-1}_{\tilde{n}_{s'}, \tilde{n}_{s'}} (\Omega^{t'})^{-1}_{\alpha_t, \tilde{n}_{s'}} C^{\eta}_{t, \tilde{n}_{s'}, \eta} C^{\lambda}_{t, \eta, \lambda} C^{\eta'}_{t, \eta', \lambda'} C^{\lambda'}_{t, \lambda'}). \]

We prove \( d_A = \sum_{\alpha_t \in L_A} d_t = \frac{|G|}{|K|} \). Using \( P^t_K = \frac{1}{|K|} \sum_{k \in K} D^t(k) \tilde{n}_m \tilde{n}_t = \delta(t, \tilde{n}_m) \in L_A \) and

\[ \frac{1}{|K|} \sum_{t \in L, \tilde{n}_m} \sum_{k \in K} d_t D^t(k) \tilde{n}_m \tilde{n}_t = \frac{|G|}{|K|} = \sum_{t \in L, \tilde{n}_t} \delta(t, \tilde{n}_t) \in L_A d_t. \] (C.7)
