SUPER CURRENTS AND TROPICAL GEOMETRY

ARON LAGERBERG

Abstract. We introduce the formalism of positive super currents on \(\mathbb{R}^n\), in strong analogy with the theory of positive currents in \(\mathbb{C}^n\). We consider intersection of currents and Lelong numbers, and as an application we show that the formalism can be used to describe tropical varieties. This is similar in spirit to the fact that in complex analysis the current of integration of an analytic variety can be identified with a closed, positive current.

In complex analysis, the natural counterpart of convexity in the real setting, is that of plurisubharmonicity, and there are many similarities between convex- and plurisubharmonic functions. For instance, a smooth function defined on \(\mathbb{R}^n\) is convex if and only if its Hessian is positive definite, and a smooth function defined on \(\mathbb{C}^n\) is plurisubharmonic iff its (complex) Hessian is positive definite. On the complex side, a natural way of studying plurisubharmonicity is provided by the framework of so called positive currents. In fact, a closed \((1,1)\)-current is positive iff it locally can be represented as \(i\partial\barpartial \varphi\) for a plurisubharmonic function \(\varphi\). However, one could argue that from the point of view of geometry, the study of positive currents rather than that of plurisubharmonic functions, is in a sense more natural. For instance, a variety of higher co-dimension than 1, relates to closed, positive currents of higher bi-degree. The aim of this paper is to introduce a notion of positive currents corresponding to convex functions defined on \(\mathbb{R}^n\). This is carried out by letting ourselves be inspired by the complex setting (indeed, many of the results and ideas will probably be familiar to the mathematician knowledgeable in pluripotential theory). The ideas can be seen as a continuation of those developed in [2]. We then consider the framework of positive currents in the context of tropical geometry,
proving, amongst other things, that every tropical hypersurface corresponds to a positive current satisfying certain criteria. This is similar in spirit to the fact that in complex analysis, a complex hypersurface can be represented by a positive current satisfying certain hypotheses. Our hope is for this work to provide a useful tool for attacking problems within tropical geometry, and for it to serve as a gateway between complex analysis and tropical geometry.

Acknowledgements. I would like to express my gratitude towards my advisor, Bo Berndtsson, for his invaluable help with writing this article.

1. Positive super forms and currents in $\mathbb{R}^n$

Let $\mathbb{V}$ and $\mathbb{W}$ denote real vector spaces of dimension $n$, with coordinates $x = (x_1, ..., x_n)$ and $\xi = (\xi_1, ..., \xi_n)$ respectively, for which we fix an isomorphism $J: \mathbb{V} \to \mathbb{W}$, such that $J(x) = \xi$. We denote its inverse by $J$ as well, so that $J(\xi) = x$, if $x \in \mathbb{V}$ is the element for which $J(x) = \xi$. One should think of $\mathbb{V}$ and $\mathbb{W}$ as two copies of $\mathbb{R}^n$ identified via the isomorphism $J$. Let $E = \mathbb{V} \times \mathbb{W} = \{(x, \xi), x \in \mathbb{V}, \xi \in \mathbb{W}\}$. The map $J$ extends to $E$ by letting $J(x, \xi) = (J(\xi), J(x))$, so that $J^2 = id$. We consider the space $\mathcal{E}$ of smooth differential forms on $E$ whose coefficients only depend on $x$.

Thus, for $x \mapsto \alpha_{KL}(x)$ smooth functions,

$$\alpha = \sum_{K,L} \alpha_{KL}(x) dx_K \wedge d\xi_L$$

is such a form, where we use the notation $dx_K = dx_{k_1} \wedge ... \wedge dx_{k_p}$ if $K = (k_1, ..., k_p)$, $|K|$ denotes the length of the vector $K$, and similarly for $|L| = q$. We use the convention that we only sum over indices $K$ and $L$ such that if $K = (k_1, ..., k_p)$ then $k_1 < ... < k_p$, and similarly for the index $L$. If $\alpha$ is of the form (1.1), we say that $\alpha$ is a form of bi-degree $(p, q)$, and write $\alpha \in \mathcal{E}^{p,q}$ where $0 \leq p, q \leq n$. A form $\alpha$ of degree $(p, p)$ is called symmetric if $\alpha_{KL} = \alpha_{LK}$ for all indices $K, L$. We identify the isomorphism $J$ with $J^*$, which is to say $J(dx_i) = d\xi_i$, and we extend $J$ to an arbitrary $(p, q)$-form by the rule

$$J \left( \sum_{K,L} \alpha_{KL}(x) dx_K \wedge d\xi_L \right) = \sum_{K,L} \alpha_{KL}(x) d\xi_K \wedge dx_L.$$

Thus a $(p, p)$-form $\alpha$ is symmetric iff $J(\alpha) = (-1)^p \alpha$. Note that we use the letter $J$ to denote several, slightly different maps, but we hope that no confusion will arise.

Finally we put $\omega = \sum_{i=1}^n dx_i \wedge d\xi_i$ and $\omega_n = \frac{1}{n!} \omega^n$. In this article, we will consider three different notions of positivity for forms:

**Definition 1.1.** A $(n, n)$-form $v$ is positive if $v = g\omega_n$ for some function $g \geq 0$.

Let $v$ be a symmetric $(p, p)$-form.

i) The $(p, p)$-form $v$ is weakly positive if

$$v \wedge \alpha_1 \wedge J(\alpha_1) \wedge ... \wedge \alpha_{n-p} \wedge J(\alpha_{n-p})$$

is a positive $(n, n)$-form for every choice of $(1, 0)$-forms $\alpha_1, ..., \alpha_{n-p}$.

ii) We say that the $(p, p)$-form $v$ is positive, if

$$v \wedge (\sigma_{n-p}) \alpha \wedge J(\alpha) \geq 0$$

for every $(n-p, 0)$-form $\alpha$, where

$$\sigma_k = (-1)^{\frac{k(k-1)}{2}}.$$
Lemma 1.2. The following properties hold:

1) For (1, 0)-forms $\alpha$,

\[ \alpha_1 \wedge J(\alpha_1) \wedge ... \wedge \alpha_p \wedge J(\alpha_p) = \sigma_p \alpha_1 \wedge \alpha_2 \wedge ... \wedge \alpha_p \wedge J(\alpha_1) \wedge ... \wedge J(\alpha_p). \]

2) If $w_i$ are strongly positive forms for $i = 1, ..., s$ and $v$ is a positive form, then $v \wedge w_1 \wedge ... \wedge w_s$ is positive.

3) The wedge product of finitely many symmetric forms is symmetric.

4) We have the following inclusions:

\[ \{\text{strongly positive forms}\} \subset \{\text{positive forms}\} \subset \{\text{weakly positive forms}\}. \]

Proof. The proof of properties 1-3 are elementary, and left to the reader. Let us prove property 4. Let $v$ be a positive $(p, p)$-form. If $\alpha_i$ are $(1, 0)$-forms for $1 \leq i \leq n - p$, property 1 above gives us the equality

\[ 0 \leq v \wedge \alpha_1 \wedge J(\alpha_1) \wedge ... \wedge \alpha_n \wedge J(\alpha_n) = v \wedge (\sigma_{n-p})^1 \alpha_1 \wedge ... \wedge \alpha_n \wedge J(\alpha_1 \wedge ... \wedge \alpha_n), \]

and thus $v$ is weakly positive, which proves the second inclusion. For the first inclusion, we note that for every $(p, 0)$-form $\beta$,

\[ \alpha_1 \wedge J(\alpha_1) \wedge ... \wedge \alpha_p \wedge J(\alpha_p) \wedge \sigma_{n-p} \beta \wedge J(\beta) = \sigma_{n-p} \sigma_p \alpha \wedge J(\alpha) \wedge \beta \wedge J(\beta) = \]

\[ = \sigma_{n-p} \sigma_p (-1)^{p(n-p)} \alpha \wedge \beta \wedge J(\alpha \wedge \beta), \]

where $\alpha = \alpha_1 \wedge ... \wedge \alpha_{n-p}$. A simple calculation shows that $\sigma_{n-p} \sigma_p (-1)^{p(n-p)} = \sigma_n$, and since $\alpha \wedge \beta \wedge J(\alpha \wedge \beta) = \sigma_n \epsilon^2$ for some constant $c$, we finally obtain that

\[ \alpha_1 \wedge J(\alpha_1) \wedge ... \wedge \alpha_p \wedge J(\alpha_p) \wedge \sigma_{n-p} \beta \wedge J(\beta) \geq 0, \]

which proves the first inclusion. \qed

The property of a form being positive is reflected in the associated matrix of the form:

**Proposition 1.3.** Let $\alpha = \sum_{K,L} \alpha_{KL} (\sigma_p \cdot dx_K \wedge d\xi_L)$ be a symmetric $(p, p)$-form. Then $\alpha$ is positive iff the matrix $(\alpha_{KL})_{K,L}$ is positive definite. Moreover, if $\alpha$ is positive, we can find $(p, p)$-forms $\gamma_K$ for which

\[ \alpha = \sum_{K} \alpha_{KK} (\sigma_p \cdot \gamma_K \wedge J(\gamma_K)), \]

where $\alpha_{KK} \geq 0$, for each $K$. 

Proof. Let \( \beta = \sum_{|J|=p} \beta_K dx_K^c \) be a \((n-p,0)\)-form, where \( K^c \) denotes the complementary multi-index to \( K \). Then

\[
\alpha \wedge (\sigma_{n-p} \cdot \beta \wedge J(\beta)) = \sum_{|K|,|L|=p} \sigma_{n-p} \sigma_p \cdot \alpha_{KL} \beta_K \beta_L dx_K \wedge dx_K^c \wedge d\xi_K^c.
\]

Thus, since \( dx_K \wedge dx_K^c \wedge d\xi_K^c = (-1)^{n(n-p)} \sigma_n \omega_n \) and since

\[
\sigma_{n-p} \sigma_p (-1)^{n(n-p)} \sigma_n = 1
\]

by direct calculations, we obtain

\[
\alpha \wedge (\sigma_{n-p} \cdot \beta \wedge J(\beta)) = \sum_{|K|,|L|=p} \sigma_{n-p} \sigma_p (-1)^{n(n-p)} \sigma_n \alpha_{KL} \beta_K \beta_L \omega_n = \sum_{|K|,|L|=p} \alpha_{KL} \beta_K \beta_L \omega_n.
\]

Hence, if \( (\beta) = (\beta_K)|_{|K|=p} \) is the vector corresponding to the form \( \beta \),

\[
\alpha \wedge (\sigma_{n-p} \cdot \beta \wedge J(\beta)) = (\beta)^t (\alpha_{LL})(\beta) \omega_n.
\]

It follows that \( \alpha \) is positive if and only if \( (\alpha_{KL})_{K,L} \) is positive definite. The second statement follows immediately from the spectral theorem for positive definite, symmetric matrices.

The set of weakly positive and strongly positive forms are convex cones, by definition dual under the paring

\[(v,w) \mapsto v \wedge w,\]

where \( v \) is a weakly positive \((p,p)\)-form and \( w \) is a strongly positive \((q,q)\)-form, and \( p + q = n \). By definition, \( v \) is weakly positive iff \( v \wedge w \) is positive for each strongly positive \( w \), and since the bidual of a convex cone is equal to the closure of the cone, we see that \( w \) is strongly positive iff \( v \wedge w \) is positive for every weakly positive \( v \). Moreover, one can show that the cone of positive forms is self-dual. At this point, we introduce the useful notation \( dx_i = dx_1 \wedge ... \wedge dx_{i-1} \wedge dx_{i+1} \wedge ... dx_n \).

Lemma 1.4. A symmetric, weakly positive \((n-1,n-1)\)-form is strongly positive. The same applies for symmetric \((1,1)\)-forms.

Proof. Let \( \alpha = \sum_{i,j=1}^n \alpha_{ij} \sigma_{n-1} \widehat{dx}_i \wedge \widehat{d\xi}_j \) be a symmetric, weakly positive \((n-1,n-1)\)-form. By definition such a form is also positive. Thus, by Proposition 1.3 we can assume that

\[
\alpha = \sum_{i=1}^n \alpha_{ii} \sigma_{n-1} \widehat{dx}_i \wedge \widehat{d\xi}_i,
\]

with \( \alpha_{ii} \geq 0 \). Thus, using property 1) of Lemma 1.2, we see that

\[
\alpha = \sum_{i=1}^n \alpha_{ii} (\sigma_{n-1})^2 dx_1 \wedge d\xi_1 \wedge ... \wedge dx_{i-1} \wedge d\xi_{i-1} \wedge dx_{i+1} \wedge d\xi_{i+1} \wedge ... \wedge dx_n \wedge \xi_n
\]

and hence, \( \alpha \) is strongly positive which proves the first statement. The second statement is a consequence of the duality between the convex cones of weakly positive respectively strongly positive forms: Let \( \alpha \) be a weakly positive \((1,1)\)-form. Then, since we have just proved that every weakly positive \((n-1,n-1)\)-forms is
strongly positive, we see that \( \alpha \cap \beta \geq 0 \) for every weakly positive \((n-1, n-1)\)-form \( \beta \). By duality, this implies that \( \alpha \) is strongly positive.

In particular, the Lemma implies that the three different notions of positivity coincides for forms of bi-degree \((0, 0), (1, 1), (n-1, n-1)\) and \((n, n)\). Thus, for such forms we will usually only use the epithet “positive”.

Let \( V, W \) be a real vector spaces of dimension \( m \), between which we fix an isomorphism \( J' \) as above, and let \( \psi : V \to V' \) be an affine map. We let \( E' = V' \times W' \). Then \( \psi \) extends, uniquely, to an affine map from \( E \) to \( E' \), which we denote by \( \tilde{\psi} \), by demanding that \( \psi \circ J = J' \circ \tilde{\psi} \). We can now define the pull-back operator \( \tilde{\psi}^* : \mathcal{E}(E') \to \mathcal{E}(E) \), by letting

\[
\tilde{\psi}^* \left( \sum_{i,j} \alpha_{ij} dx_I \wedge d\xi_J \right) = \sum_{i,j} (\alpha_{ij} \circ \tilde{\psi}) \psi^*(dx_I) \wedge \psi^*(d\xi_J)
\]

where, if \( I = (i_1, \ldots, i_p) \), we as usual let \( \psi^*(dx_I) = \psi^*(dx_{i_1}) \wedge \ldots \wedge \psi^*(dx_{i_p}) \), and analogously for \( \psi^*(d\xi_J) \). Observe that the pull-back operator commutes with the operator \( J' \), and also with the operator \( d \). When no confusion seems likely to arise, we will denote the extension \( \tilde{\psi} \) by \( \psi \). Note that if we did not demand \( \psi \) to be affine, the pullback of a form in \( E \) could have coefficients depending on the variable \( \xi \), and thus not be a map from \( \tilde{\mathcal{E}} \) to \( \mathcal{E} \). If \( \psi : E \to E' \) is an affine map, an easy computation shows that

\[
\psi^*(\omega_n) = |\text{det}(\psi)|^2 \omega_n.
\]

This implies that if \( \psi \) corresponds to a change of coordinates, \( \psi^* \omega_n = c \omega_n \) for some constant \( c > 0 \). Thus, positivity does not depend on the form \( \omega \) which we use as a reference. If \( \psi \) corresponds to an inclusion of a subspace \( V \subset V' \), we call \( \psi^*(\alpha) \) the restriction of the form \( \alpha \) to the subspace \( V \).

**Proposition 1.5.** With the above notation the following holds: \( \alpha \) is a weakly positive \((p, p)\)-form on \( \mathbb{R}^n \), iff the restriction of \( \alpha \) to every \( p \)-dimensional subspace is positive, that is, if \( \psi^*(\alpha) \) is positive for every inclusion map \( \psi : V \to V' \), where \( V \) is a \( p \)-dimensional subspace of \( \mathcal{V}' \).

**Proof.** Suppose that \( \alpha \) is a \((p, p)\)-form such that \( \psi^* \alpha \) is positive for every inclusion map \( \psi : V \to V' \) where \( V \) is a \( p \)-dimensional subspace of \( \mathcal{V}' \). By choosing a basis on \( \mathcal{V}' \) we can identify \( \mathcal{V}' \) with \( \mathbb{R}^m \), and regard \( \mathcal{V} = \psi(\mathcal{V}) \) as a \( p \)-dimensional subspace of \( \mathbb{R}^m \). We need to show that, for any \((1, 0)\)-forms \( e_i \), the number \( c \) defined by

\[
c \omega_m := \alpha \wedge v_{p+1} \wedge J(v_{p+1}) \wedge \ldots \wedge v_m \wedge J(v_m)
\]

satisfies \( c \geq 0 \). To this end, assume that \( v_{p+1}, \ldots, v_m \) are linearly independent \((1, 0)\)-forms on \( \mathcal{V}' \). These correspond to independent vectors \( e_{p+1}, \ldots, e_m \) in \( \mathbb{R}^m \), which we can extend to a basis \( \{e_1, \ldots, e_m\} \) of \( \mathcal{V}' \), with corresponding forms \( v_i \). We define two maps: the first, \( \psi : \mathbb{R}^p \to \mathbb{R}^m \), is given by \( \psi(x_1, \ldots, x_p) = \sum_{i=1}^p x_i e_i \) and the second, \( \sigma : \mathbb{R}^{m-p} \to \mathbb{R}^m \), is defined by \( \sigma(x_{p+1}, \ldots, x_m) = \sum_{i=p+1}^m x_i e_i \). Using these two maps, we can define the invertible affine map \( \Gamma : \mathbb{R}^m \to \mathbb{R}^m \) given by \( \Gamma(x_1, \ldots, x_m) = \psi(x_1, \ldots, x_p) + \sigma(x_{p+1}, \ldots, x_m) \).

Then

\[
\Gamma^*(\omega_m) = \Gamma^*(\alpha) \wedge \Gamma^*(v_{p+1} \wedge J(v_{p+1}) \wedge \ldots \wedge v_m \wedge J(v_m)) = \\
\psi^*(\alpha) \wedge dx_{p+1} \wedge d\xi_{p+1} \wedge \ldots \wedge dx_m \wedge d\xi_m,
\]

which, by assumption, is a positive \((m, m)\)-form. By formula (1.2) we see that \( c \geq 0 \), as desired. Conversely, if \( \alpha \) is a weakly positive \((p, p)\)-form on \( \mathcal{E}' \) and
ψ : V → V′ is a linear map of rank p (which thus corresponds to an inclusion) we let \{e_1, ..., e_m\} be a basis of V′ ⊃ ℝ^n such that \{e_1, ..., e_p\} spans the column space of ψ, and define Γ as above. Then equation (1.3) is still valid, showing that ψ*(α) is a positive multiple of ω_p. □

We want to define the integral of an (n, n)—form over the space E. For this, we assume that the vector space V is endowed with an inner product (·, ·), and choose an orthonormal basis \{e_1, ..., e_n\}, with corresponding coordinates (x_1, ..., x_n). We endow W with the same structure via the isomorphism J. Then dx_1 ∧ ... ∧ dx_n is a (n, 0) form on V, dξ_1 ∧ ... ∧ dξ_n is an (0, n)—form on W, and every (n, n)-form α can be written as

\[ α = α_0(x) dx_1 ∧ ... ∧ dx_n ∧ dξ_1 ∧ ... ∧ ξ_n, \]

for some function α_0 on V.

**Definition 1.6.** The integral of an (n, n)—form α as above is given by

\[ \int_E α = \int_V α_0(x) dx_1 ∧ ... ∧ dx_n. \]

The above definition depends only on the inner product chosen. Indeed, if we choose a different orthonormal basis, say \{e_1', ..., e_n'\}, the map ψ which sends e_i to e_i' have determinant 1 or −1. In either case, by formula (1.2) this means that

\[ \int_E ψ^*(α) = (±1)^2 \int_E α = \int_E α. \]

Thus the definition is independent of which orthonormal basis we choose to work with. In particular, it does not depend on any orientation of V. One can also understand the definition as follows: the choice of inner product allows us, as above, to choose a volume-element dξ_1 ∧ ... ∧ dξ_n on W, the total volume of which we define to be

\[ \int_W dξ_1 ∧ ... ∧ dξ_n = 1. \]

Then, by formally applying Fubini’s theorem,

\[ \int_E α_0(x) dx_1 ∧ ... ∧ dx_n ∧ dξ_1 ∧ ... ∧ ξ_n = \int_V α_0(x) dx_1 ∧ ... ∧ dx_n \cdot \int_W dξ_1 ∧ ... ∧ ξ_n = \]

\[ = \int_V α_0(x) dx_1 ∧ ... ∧ dx_n. \]

If Ω ⊂ V is open, we define

\[ \int_{Ω×W} α = \int_Ω χ_Ω(x) \cdot α_0(x) dx_1 ∧ ... ∧ dx_n ∧ dξ_1 ∧ ... ∧ ξ_n, \]

where χ_Ω denotes the characteristic function of the set Ω. By formula (1.2) we have the following change of variable formula for a non-singular, affine map ψ : V → V′:

\[ \int_E ψ^* α = \int_V \left| \text{det}(ψ) \right|^2 α_0(ψ(x)) dx_1 ∧ ... ∧ dx_n = \left| \text{det}(ψ) \right| \int_E α. \]

If L ⊂ V is an oriented submanifold of dimension k, and if α = \sum_{|I|=k} α_I(x) dx_I ∧ dξ_1 ∧ ... ∧ dξ_n is an arbitrary (k, n)—form, we define the integral of α over L × W by

\[ \int_{L×W} \left( \sum_{|I|=k} α_I(x) dx_I ∧ dξ_1 ∧ ... ∧ dξ_n \right) = \sum_{|I|=k} \int_L α_I(x) dx_I. \]
Remark 1.7. It might be interesting at this point to compare with the complex setting. First of all, the map $J$ could be compared with the usual complex structure which identifies $\mathbb{C}^n$ with $\mathbb{R}^n + i\mathbb{R}^n$. Under this identification we compactify the imaginary directions by considering $\mathbb{R}^n + i\mathbb{R}^n/\mathbb{Z}^n$. A convex function $f$ on $\mathbb{R}^n$ can then be regarded as a plurisubharmonic function on $\mathbb{R}^n + i\mathbb{R}^n/\mathbb{Z}^n$, by demanding the extension to be independent of the imaginary directions. In a similar way, we can consider a real $n$–form $\alpha$ as a complex $(n,n)$–form $\tilde{\alpha}$, and in a natural way,

$$\int_{\mathbb{R}^n + i\mathbb{R}^n/\mathbb{Z}^n} \tilde{\alpha} = \int_{\mathbb{R}^n} \alpha,$$

which could be seen as an analogue of our definition,

$$\int_{\mathbb{R}^n} d\xi_1 \wedge \ldots \wedge d\xi_n = 1.$$

Generalizing this slightly, we use another lattice in order to compactify the imaginary directions. Thus, if $\Gamma$ is any lattice, we consider $\mathbb{R}^n + i\mathbb{R}^n/\Gamma$. Such a lattice induces an inner product on $\mathbb{R}^n$. Indeed, $\Gamma$ is isomorphic to $\mathbb{Z}^n$ via an affine map, and there is a one-to-one correspondence between affine maps and inner products. In this sense, we can say that choosing an inner product on $\mathbb{R}^n$ (thereby defining integration of $(p,p)$–forms along $p$-dimensional subspaces of $E$) corresponds to compactifying using a lattice as above, and vice versa.

We define the operator $d : \mathcal{E}^{p,q} \to \mathcal{E}^{p+1,q}$ by the formula

$$d(\sum_{|I|=p,|J|=q} \alpha_{IJ} dx_I \wedge d\xi_J) = \sum_{|I|=p,|J|=q} (\sum_{i=1}^n \frac{\partial \alpha_{IJ}(x)}{\partial x_i} dx_i \wedge dx_I \wedge d\xi_J).$$

In our setting, we have the following version of Stokes’ formula.

**Proposition 1.8.** For $\Omega \subset \mathbb{V}$ a smoothly bounded, open subset, and $\alpha$ an $(n-1,n)$–form on $\mathbb{E}$,

$$\int_{\partial \Omega \times \mathbb{W}} d\alpha = \int_{\Omega \times \mathbb{W}} d\alpha.$$

**Proof.** By the usual Stokes’ formula, we have that

$$\int_{\Omega \times \mathbb{W}} d\alpha = \sum_{\partial \Omega} \int_{\Omega \times \mathbb{W}} d(\alpha_{IJ}(x)dx_I) \wedge d\xi_J = \sum_{\partial \Omega} \int_{\Omega} d(\alpha_{IJ}(x)dx_I) \int_{\mathbb{W}} d\xi_J =

= \sum_{\partial \Omega} \int_{\Omega} (\alpha_{IJ}(x)dx_I) \int_{\mathbb{W}} d\xi_J = \int_{\partial \Omega \times \mathbb{W}} \alpha.$$

□

We define the operator $d^\# : \mathcal{E}^{p,q} \to \mathcal{E}^{p,q+1}$ by

$$d^\# = J \circ d \circ J,$$

which in coordinates is equivalent to

$$d^\# = \sum_{j=1}^n \partial x_j \wedge d\xi_j.$$

As immediately follows from the definition, $d^2 = (d^\#)^2 = 0$, and moreover, $d^\# \circ J = J \circ d$. 
1.1. Currents and positivity. In this section, we assume the reader to be familiar with the basic theory of currents, but we include some proofs to illustrate the setting in which we work. The precise definition of a current is tedious and almost identical to the complex case, so we refer to [3] for the details. The basic idea is that by introducing a topology on $D^{p,q} = \{ \alpha \in \mathcal{E}^{p,q}; \alpha \text{ has compact support} \}$, we can consider the topological dual of $D^{p,q}$, which we define to be the space of currents $D_{n-p,n-q}$. Suffice it so say that an element of $D_{n-p,n-q}$ can be viewed as a $(n-p,n-q)$–form whose coefficients are distributions which only acts on $\mathbb{V}$, that is, the coefficients are “independent of $\xi$”. Thus every $T \in D_{p,q}$ can be written as

$$T = \sum_{|I|=p, |J|=q} T_{IJ} dx_I \wedge d\xi_J,$$

where $T_{IJ}$ are uniquely defined distributions on $\mathbb{V}$. We denote the paring between an element $\alpha \in D^{p,q}$ and $T \in D_{n-p,n-q}$ by $\langle T, \alpha \rangle$, and we use the convention that

$$\langle T_{IJ} dx_I \wedge d\xi_J, \alpha_0 dx_{I'} \wedge d\xi_{J'} \rangle = \pm \langle T_{IJ}, \alpha_0 \rangle,$$

where the sign is determined by the sign of the permutation sending $dx_I \wedge d\xi_J \wedge dx_{I'} \wedge d\xi_{J'}$ to $\omega_n$. For convenience, when a current acts on an element of $\mathcal{E}$, we always assume this element to have compact support, without explicitly stating so. As usual we can define $dT$, $d^\# T$, $dd^\# T$ by $\langle dT, \alpha \rangle = \pm \langle T, d\alpha \rangle$ and so forth. Thus we say that a current $T$ is $d-$closed if $dT = 0$, and similarly for $d^\#$. These operators so defined, act continuously on the space of currents.

Now, let $\rho$ be a smooth, radial function with support in the unit ball, satisfying $\int \rho = 1$, and put $\rho_\epsilon(x) = \frac{1}{\epsilon^n} \rho(\frac{x}{\epsilon})$, for $\epsilon > 0$. If we consider the convolution of a current $T = \sum_{|I|=p, |J|=q} T_{IJ} dx_I \wedge d\xi_J$ with this function $\rho_\epsilon$, defined in the usual way as

$$T * \rho_\epsilon = \sum_{|I|=p, |J|=q} (T_{IJ} * \rho_\epsilon) dx_I \wedge d\xi_J,$$

then $\{T * \rho_\epsilon\}_{\epsilon>0}$ defines a family in $\mathcal{E}^{p,q}$ converging weakly to the current $T$, as $\epsilon \to 0$. We call this family a regularization of the current $T$, and it is easy to see that if $dT = 0$, then $d(T * \rho_\epsilon) = 0$, so regularization preserves the property of being closed.

**Lemma 1.9.** Let $\Omega \subset \mathbb{V}$ be an open set. For a $d-$closed current $T \in D_{p,q}(\Omega \times \mathbb{W})$ there exists a $T' \in \mathcal{E}^{p,q}(\Omega \times \mathbb{W})$ such that $T - T' = dR$ for some $R \in D_{p-1,q}(\Omega \times \mathbb{W})$.

**Proof.** Let

$$T = \sum_{|I|=p, |J|=q} T_{IJ} dx_I \wedge d\xi_J.$$ 

If we denote by $S_J$ the $(p,0)$-currents $\sum_{|I|=p} T_{IJ} dx_I$, then

$$T = \sum_{|J|=q} S_J \wedge d\xi_J,$$

and by the hypothesis $dS_J = 0$. It is well known from theory of currents in $\mathbb{V}$, that for every such $S_J$ there is a smooth $(p,0)$–form $S'_J$ such that $S_J - S'_J = dR_J$ for some $(p-1,0)$–current $R_J$ (where we identify $(p,0)$–currents on $\mathbb{E}$ with $p$–currents
on \( \mathbb{V} \). Thus, if we let \( T' = \sum_{|J|=q} S_J' \wedge d\xi_J \), and \( R = \sum_{|J|=q} R_J \wedge d\xi_J \) we have that \( T' \) is smooth and
\[
T - T' = \sum_{|J|=q} (S_J - S_J') \wedge d\xi_J = \sum_{|J|=q} dR_J \wedge d\xi_J = d \sum_{|J|=q} R_J \xi_J = dR,
\]
as required. \( \square \)

**Proposition 1.10.** Let \( \Omega \subset \mathbb{V} \) be a star shaped open subset. If \( T \in D_{p,q}(\Omega \times \mathbb{W}) \) is d-closed, in the sense that \( dT = 0 \), and \( q \geq 1 \), then there exists an element \( \tilde{T} \in D_{p-1,q}(\Omega \times \mathbb{W}) \) such that \( d\tilde{T} = T \). An analogous statement holds if \( T \) is instead \( d^\# \)-closed.

**Proof.** By Lemma 1.9, it suffices to show the proposition in the case where \( T \) has smooth coefficients, that is, \( T \in \mathcal{E}^{p,q} \). To this end assume that
\[
T = \sum_{|J|=p,|I|=q} T_{I,J} dx_I \wedge d\xi_J,
\]
with \( T_{I,J} \) smooth. If we, as above, denote by \( S_J \) the \((p,0)\)-forms \( \sum_{|I|=p} T_{I,J} dx_I \), then \( T = \sum_{|J|=q} S_J \wedge d\xi_J \), and since \( dT = \sum_{|J|=q} (dS_J) \wedge d\xi_J = 0 \) by the hypothesis, we see that \( dS_J = 0 \). Since \( \Omega \) is star shaped, the Poincaré lemma tells us that there exists \((p-1,0)\)-forms, \( \tilde{S}_J \) such that \( d\tilde{S}_J = S_J \). Thus, if we consider the \((p-1,q)\)-form \( \tilde{T} = \sum_{|J|=q} \tilde{S}_J \wedge d\xi_J \), we see that it satisfies
\[
d\tilde{T} = \sum_{|J|=q} d\tilde{S}_J \wedge d\xi_J = \sum_{|J|=q} S_J \wedge d\xi_J = T.
\]
If \( T \) is instead \( d^\# \)-closed, the same argument as above still applies with the obvious changes. \( \square \)

We now come to the corresponding notions of positivity for currents.

**Definition 1.11.** We say that a symmetric \((p,p)\)-current \( T \) is weakly positive if
\[
\langle T, \alpha \rangle \geq 0
\]
for each smooth strongly positive \((n-p, n-p)\)-form \( \alpha \) with compact support. \( T \) is positive if
\[
\langle T, \sigma_{n-p} \wedge J(\beta) \rangle,
\]
for every smooth \((p,0)\)-form \( \beta \) with compact support.

We postpone the definition of a strongly positive \((p,p)\)-current until section 2.

**Proposition 1.12.** A function \( f : \mathbb{V} \to \mathbb{R} \) is convex iff \( dd^\# f \) is a positive \((1,1)\)-current.

**Proof.** This is clear if \( f \) is smooth since the matrix associated to \( dd^\# f \) is the Hessian of \( f \), so we can apply Proposition 1.3. The general case follows by approximation: if \( f \) is convex but not smooth, we can find a family \( \{ f_\varepsilon \} \) of smooth, convex functions such that \( f_\varepsilon \to f \). Using the definition of currents, we see that \( dd^\# f_\varepsilon \to dd^\# f \) in the weak sense, and thus, \( \langle dd^\# f, \alpha \rangle = \lim_{\varepsilon \to 0} \langle dd^\# f_\varepsilon, \alpha \rangle \geq 0 \), for every positive \((n-1, n-1)\)-form \( \alpha \). Hence \( dd^\# f \geq 0 \). Conversely, if \( dd^\# f \geq 0 \), we put \( f_\varepsilon(x) = f(y) \rho_\varepsilon(x-y) \) where \( \rho_\varepsilon \) is the regularizing kernel from above. One easily verifies that \( dd^\# f_\varepsilon \geq 0 \) and hence \( f_\varepsilon \) is convex. Moreover, \( f_\varepsilon \) is smooth, \( f_\varepsilon \geq f \) and \( f_\varepsilon \to f \) uniformly on compacts. Thus \( f \) is convex, as desired. \( \square \)
Of course, if $f$ is also smooth, then $dd^c f$ is a positive, closed $(1,1)$–form. The following proposition is fundamental for what is to come; it is the counterpart in our setting of the so called $dd^c$-lemma from complex analysis:

**Proposition 1.13.** *(dd$^c$–lemma)* Let $T$ be a closed, positive $(1,1)$-current on $\mathbb{E}$. Then there exists a convex function $f : \mathbb{E} \to \mathbb{R}$ for which

$$T = dd^c f.$$ 

**Proof.** By regularization, we can assume $T$ to be smooth. Since $T$ is also closed, by Proposition 1.10 we can find a smooth $(0,1)$–current

$$S = \sum_{i=1}^{n} S_i d\xi_i$$

such that $T = dS$. Moreover, $T$ being symmetric implies $\frac{\partial}{\partial x_j} S_i = T_{ij} = T_{ji} = \frac{\partial}{\partial x_i} S_j$, and so we see that

$$d^c S = \sum_{i,j=1}^{n} \frac{\partial}{\partial x_j} S_i d\xi_j \wedge d\xi_i = 0.$$ 

Another application of Proposition 1.10 provides us with a function $f$ such that $S = d^c f$. We conclude that

$$T = dd^c f,$$

and since $T$ is positive, $f$ must be convex. □

Using this proposition we can show the following:

**Proposition 1.14.** If $T$ is a closed, positive $(1,1)$-current, then each component of $(\text{Supp} T)^c$ is convex.

**Proof.** By the $dd^c$-lemma we can find a convex function $f$ such that $T = dd^c f$. If $A$ is a component of $(\text{Supp} T)^c$, so that $dd^c f = 0$ on $A$, then $f$ is affine on $A$. For every pair of points $p, q \in A$ we consider the line segment $I$ connecting the two points. The restriction of $f$ to $A$ is an affine function and the convexity of $f$ implies that it must be affine on the whole line segment $I$. Since this is true for every line segment $I$ connecting two points of $A$ we see that $f$ must be affine on the convex hull of $A$, so that $A \subset \text{conv}(A) \subset \text{Supp} T^c$. Since $A$ was a component we must have $A = \text{conv}(A)$, that is, $A$ is convex. □

### 2. Intersection theory of currents

Let $M_p$ denote the space of $(p,p)$-forms on $\mathbb{E}$ whose coefficients are measures, endowed with the following topology: if $T_i, T \in M_p$ then $T_i \to T$ iff $T_i(\alpha) \to T(\alpha)$ for every $(n-p,n-p)$–form $\alpha$ with compact support and whose coefficients are continuous functions. Note that $M_p \subset D_{p,p}$ as a set, but the topology of $M_p$ is stronger than that induced by $D_{p,p}$. However, a standard proposition in the setting of currents with measure coefficients, which carries over to our case, is the following (cf. [6]):

**Proposition 2.1.** Let $T_i, T \in M_p$. Then $T_i \to T$ in $M_p$ if and only if

$$T_i(\alpha) \to T(\alpha),$$

where $\alpha$ is a $(n-p,n-p)$–form.
for every compactly supported, smooth \( (n-p,n-p) \)-form \( \alpha \), and if for every compact subset \( L \subset \mathbb{R}^n \) we have,
\[
\sup_i \max_{I,J} |(T_i)_{IJ}|(L) < +\infty.
\]

Here, if \( \mu \) is a measure \( |\mu| \) denotes the total variation of \( \mu \). Now, let us consider the map given by
\[
\Psi_p(f_1, \ldots, f_p) = \frac{dd^c}{dV} f_1 \wedge \cdots \wedge \frac{dd^c}{dV} f_p,
\]
where \( f_i \) is smooth and convex for each index \( i \); let us denote the set of such functions by \( K \). We consider \( \Psi_p \) as a map from \( K^p \) to \( M_p \). Our aim is to show that this map extends, in a natural way, to a map defined on \( p \)-tuples of convex functions (that need not be smooth). By the inclusion \( M_p \subset D_{p,p} \), this extension can be considered as a \((p,p)\)-current, which we will call the intersection product.

The scheme to prove this extension property is the following: first we prove that \( \Psi_p \) maps bounded subsets of \( K^p \) to bounded subsets of \( M_p \). By the Banach-Alaoglu theorem, this implies that for every bounded subset \( A \subset K^p \), the family \( \{ \Psi_p(x), x \in A \} \) contains a weakly convergent subsequence. Thus there exist at least one accumulation point of \( \{ \Psi_p(x), x \in A \} \) in \( M_p \), and we then show that, in fact, there exists only one, unique accumulation point. Before we turn to the details, we need an important property of positive currents:

**Proposition 2.2.** If
\[
T = \sum_{|I|=|J|=p} T_{IJ} (\sigma_p \cdot dx_I \wedge d\xi_J)
\]
is a symmetric, positive \((p,p)\)-current, then each coefficient \( T_{IJ} \) satisfies
\[
|\langle T_{IJ}, \phi \rangle| \leq C \sum_{|I|=p} \langle T_{II}, \phi \rangle,
\]
for each smooth, non-negative function with compact support, \( \phi \). In particular, \( T_{II} \) is a positive measure, and \( T_{IJ} \) is a signed measure, for each multi-indices \( I,J \).

**Proof.** The argument is clearest when \( T \) is smooth, so let us first assume this is the case. By Proposition 1.3, the \( p^2 \times p^2 \) matrix \( (T_{IJ}) \), is positive definite and symmetric at every point of \( \mathbb{R}^n \), and thus defines a metric \( g \) on \( \mathbb{R}^{p^2} \). Let \( (e_I)_{|I|=p} \) be an orthonormal basis of \( \mathbb{R}^{p^2} \) such that \( g(e_I, e_J) = T_{IJ} \). Then the Cauchy-Schwartz inequality gives us
\[
T_{IJ} = g(e_I, e_J) \leq \sqrt{g(e_I, e_I) \cdot g(e_J, e_J)} = \sqrt{T_{II} \cdot T_{JJ}} \leq \frac{T_{II} + T_{JJ}}{2},
\]
where we used the inequality between geometric and arithmetic mean in the last inequality. By exchanging \( e_I \) for \(-e_I\) in (2.2) we have established the inequality
\[
|T_{IJ}(x)| \leq C \sum_{|I|=p} T_{II}(x)
\]
for some constant \( C > 0 \), which proves the proposition when \( T \) is smooth. If \( T \) is not smooth, we can still define an associated metric as follows: for each smooth, non-negative function with compact support, \( \phi \), we define
\[
g(e_I, e_J) = \langle T, \sigma_p \cdot \phi dx_I \wedge d\xi_J \rangle,
\]
where \( \sigma_p \cdot \phi \) is the \( p \)-current associated to \( \phi \).
and extend by linearity. Then $g$ is a positive definite, symmetric form on $\mathbb{R}^p$, since, if $v = \sum_i v_i e_i \in \mathbb{R}^p$, then

$$g(v, v) = \left( T, \sigma_{n-p} \hat{\phi}(\sum_i v_i dx_i) \wedge J(\sum_i v_i dx_i) \right) = \left( T, \sigma_{n-p} \hat{\nu} \wedge J(\hat{v}) \right) \geq 0,$$

where $\hat{v} = \sqrt{\sigma} \sum_i v_i dx_i$. Thus, $g(e_1, e_I) = \langle T_{1I}, \phi \rangle \geq 0$, which implies that $T_{1I}$ is a positive measure. Moreover, $g(e_I, e_J) = \langle T_{1I}, \phi \rangle$, and by the argument used above,

$$| \langle T_{1J}, \phi \rangle | \leq C \cdot \sum_{|I| = p} \langle T_{1I}, \phi \rangle,$$

for some constant $C > 0$. The proposition follows. \hfill \Box

A subset $A \subset K^p$ is bounded if for every compact subset $L$, and every element $(f_1, \ldots, f_p) \in A$, we have that

$$\max_{i} \sup_{x \in L} |f_i(x)| \leq C_L,$$

for some constant $C_L$ (these norms, indexed by $L$, define the topology of $K^p$).

**Proposition 2.3.** If $A \subset K^p$ is bounded, then for each compact set $L \subset \mathbb{R}^n$, there exists a constant $D_L$ such that if

$$T = dd^# f_1 \wedge \ldots \wedge dd^# f_p$$

where $(f_1, \ldots, f_p) \in A$, the coefficients of $T$ satisfy

$$|T_{1I}|(L) := \int_L |T_{1I}| \leq D_L.$$

**Proof.** By the previous proposition, we need only to prove that $T_{1I} \leq D_L$, for every $I$. Assume first that $p = 1$. Fix a set compact set $L$ and let $f \in K$. Moreover, let $\chi$ be a smooth function equal to 1 on $L$ and 0 outside a small neighbourhood of $L$. Then, since $\partial^2_i f \geq 0$, by partial integration we get,

$$| \int_L \partial^2_i f | \leq | \int_{\mathbb{R}^n} \chi(x) dd^# f(x) \wedge d\xi_i | \leq \sup_{x \in \text{Supp} f} |f(x)| \cdot C_{x},$$

using that $\chi$ has uniformly bounded second-order partial derivatives on every compact subset. Thus, there exists a constant $D_L$ such that

$$|T_{1i}|(L) \leq D_L$$

for each $i$, proving the case $p = 1$. Assume now that we have proven the proposition for $p = k - 1$. We want to show that it holds for $p = k$ as well. To this end, let $S = dd^# f_2 \wedge \ldots \wedge dd^# f_k$, and fix a multi-index $I$ of length $k$. Then, using the same notation as in the case $p = 1$,

$$| \int_L (dd^# f_1 \wedge S)_{1I} dV | \leq | \int_{\mathbb{R}^n} \chi(x) dd^# f_1(x) \wedge S \wedge d\xi_i | = \int_{\text{Supp} \times \mathbb{R}^n} f_1(x) dd^# \chi(x) \wedge S \wedge d\xi_i \wedge d\xi_I |,$$
By the induction hypothesis, $S$ has coefficients satisfying $|S_{IJ}|(\text{Supp}\chi) \leq D_{\text{Supp}\chi}$. Thus
\[
|\int_L (dd^\# f_1 \wedge S)_{IJ} dV| \leq \sup_{x \in \text{Supp}\chi} |f_1(x)| \cdot C_x,
\]
and we are done.

\hfill \square

**Proposition 2.4.** Let $f_1, \ldots, f_p$ be convex (but not necessarily smooth) functions, and let, for each $i$, $\{f^k_i\}_k$ be a sequence of smooth, convex functions converging uniformly to $f_i$ on compact subsets. Then the sequence $\{dd^\# f^k_1 \wedge \ldots \wedge dd^\# f^k_p\}_k \subset M_p$ contains a convergent subsequence. If $\{g^k_i\}_k$ is another sequence of smooth convex functions converging uniformly on compact subsets, to $f_i$ for each $i$, then, if the limits of $dd^\# f^k_1 \wedge \ldots \wedge dd^\# f^k_p$ and $dd^\# g^k_1 \wedge \ldots \wedge dd^\# g^k_p$ exist, they must be equal.

\noindent Proof. Let $A = \{(f^k_1, \ldots, f^k_p), k \geq 1\}$. Obviously, the set $A$ is bounded. Using Proposition 2.3, we see that for each compactly supported $(n - p, n - p)$-form $\alpha$ with continuous coefficients, there exists a constant $D_\alpha$, for which
\[
(dd^\# f^k_1 \wedge \ldots \wedge dd^\# f^k_p)(\alpha) \leq D_\alpha \cdot \max_{I,J} \sup_{x \in \text{Supp}\alpha} |\alpha_{IJ}(x)|.
\]
Thus, applying the Banach-Alaoglu theorem, we see that the sequence $\{dd^\# f^k_1 \wedge \ldots \wedge dd^\# f^k_p\}_k$ contains a convergent subsequence in $M_p$, as desired. To prove the second statement, we first assume that $p = 1$ and let $\alpha$ be a smooth, compactly supported $(n - 1, n - 1)$-form. Then,
\[
|\int_E (dd^\# f^k_1 - dd^\# g^k_1) \wedge \alpha| = |\int_E (f^k_1 - g^k_1) \wedge dd^\# \alpha| \leq \sup_{x \in \text{Supp}\alpha} |f^k_1 - g^k_1| \cdot C_\alpha
\]
which tends to 0 as $k \to \infty$. This proves that the limit is equal in $D^{1,1}$. However, by Proposition 2.3 both of the forms $dd^\# f^k_1$ and $dd^\# g^k_1$ satisfy (2.1), and so, by Proposition 2.1 $dd^\# f^k_1$ and $dd^\# g^k_1$ converge to the same limit in $M_p$, as well. Now, assume the statement is proved for $p = m - 1$, and let $S^k = dd^\# f^k_2 \wedge \ldots \wedge dd^\# f^k_p$. Then, since $S^k$ is closed,
\[
\int_E (dd^\# f^k_1 - dd^\# g^k_1) \wedge \alpha \wedge S^k = \int_E (f^k_1 - g^k_1) \wedge dd^\# \alpha \wedge S^k,
\]
where $\alpha$ is a test-form of degree $(n - p, n - p)$. Moreover, by Proposition 2.3 the coefficients of $S^k$ satisfy
\[
|S^k_{IJ}|(\text{Supp}\alpha) \leq C_\alpha.
\]
Thus there exists a constant $D_\alpha$ for which,
\[
|\int_E (dd^\# f^k_1 - dd^\# g^k_1) \wedge \alpha \wedge S^k| \leq D_\alpha \sup_{x \in \text{Supp}\alpha} |f^k_1 - g^k_1|.
\]
This last expression thus tends to 0 as $k \to \infty$. Again, by Proposition 2.3 and Proposition 2.1 we are done. \hfill \square

We can now define the intersection product $dd^\# f_1 \wedge \ldots \wedge dd^\# f_p$, for $f_1, \ldots, f_p$ convex functions on $\mathbb{R}^n$, by using the continuity of $\Psi_p$: it is well known that for a convex function $f$ one can find a sequence of smooth, convex functions $f^k$ which is monotone in $k$, and which converge to $f$ pointwise. By Dini's theorem (for its statement, see the discussion after equation (2.10)), $f^k$ converges uniformly to
f on every compact subset of \( \mathbb{R}^n \). Applying this for each function \( f_i \), by using Proposition 2.4 we can define (after possibly choosing a subsequence),
\[
dd^\# f_1 \wedge ... \wedge \dd^\# f_p = \lim_{k \to \infty} \dd^\# f_{1}^k \wedge ... \wedge \dd^\# f_{p}^k,
\]
and the definition does not depend on the way we approximate the functions \( f_i \) (or which subsequence we choose).

**Definition 2.5.** A strongly positive \((p, p)\)-current is a current of the form \( \dd^\# f_1 \wedge ... \wedge \dd^\# f_p \).

Note that such currents are automatically closed. We collect some immediate observations about such currents in a proposition:

**Proposition 2.6.** The intersection product \( \dd^\# f_1 \wedge ... \wedge \dd^\# f_p \) is weakly positive, it is symmetric in its arguments, and its coefficients are measures. Moreover, it satisfies the relation
\[
(2.4) \quad \text{Supp}(\dd^\# f_1 \wedge ... \wedge \dd^\# f_p) \subset \text{Supp}(\dd^\# f_1) \cap ... \cap \text{Supp}(\dd^\# f_p).
\]

We also have the following stability property:

**Proposition 2.7.** Let \( f, g_1, ..., g_p \) be convex functions, where \( p < n \). If \( \{ f_i \} \) is a family of continuous functions converging pointwise to \( f \), for which \( \sup_{x \in K} f_i(x) \) is bounded for every compact set \( K \subset \mathbb{V} \), then
\[
\lim_{\epsilon \to 0} \dd^\# f_\epsilon \wedge \dd^\# g_1 \wedge ... \wedge \dd^\# g_p = \dd^\# f \wedge \dd^\# g_1 \wedge ... \wedge \dd^\# g_p.
\]

**Proof.** Since the current \( \dd^\# g_1 \wedge ... \wedge \dd^\# g_p \) has measure coefficients when written in coordinates, we see that if \( \alpha \) is a compactly supported, smooth \((n - p - 1, n - p - 1)\)-form, the \((n, n)\)-current \( \dd^\# g_1 \wedge ... \wedge \dd^\# g_p \wedge \dd^\# \alpha \) can be represented by a positive measure on \( \mathbb{R}^n \) with compact support. By the dominated convergence theorem,
\[
\lim_{\epsilon \to 0} \langle \dd^\# f_\epsilon \wedge \dd^\# g_1 \wedge ... \wedge \dd^\# g_p, \alpha \rangle = \lim_{\epsilon \to 0} \int_{\mathbb{V}} f_\epsilon \wedge \dd^\# g_1 \wedge ... \wedge \dd^\# g_p \wedge \dd^\# \alpha = \int_{\mathbb{V}} f \wedge \dd^\# g_1 \wedge ... \wedge \dd^\# g_p \wedge \dd^\# \alpha = \langle \dd^\# f \wedge \dd^\# g_1 \wedge ... \wedge \dd^\# g_p, \alpha \rangle,
\]
which proves the claim. \( \square \)

**Proposition 2.8.** If \( f^1, ..., f^p \) are convex functions, and for each \( i \in \{ 1, ..., p \} \) there is a family of convex functions \( \{ f^i_{\epsilon_i} \}_{\epsilon_i > 0} \) such that
\[
\lim_{\epsilon_i \to 0} f^i_{\epsilon_i}(x) = f^i(x),
\]
for every \( x \in \mathbb{V} \), and which satisfy that \( \sup_{x \in K} f^i_{\epsilon_i}(x) \) is bounded for every compact set \( K \subset \mathbb{V} \) and for each \( i \). Then
\[
(2.5) \quad \lim_{\epsilon_1 \to 0} ... \lim_{\epsilon_p \to 0} \dd^\# f^1_{\epsilon_1} \wedge ... \wedge \dd^\# f^p_{\epsilon_p} = \dd^\# f^1 \wedge ... \wedge \dd^\# f_p,
\]
for any permutation \((i_1, ..., i_p)\) of the n-tuple \((1, ..., p)\).

**Proof.** The assumption that the families consist entirely of convex functions ensures that the expression inside the limit in (2.5) is strongly positive. Thus, we can apply Proposition 2.7 successively to obtain the desired conclusion. \( \square \)
Definition 2.9. The Monge-Ampère measure of a convex function $f$ is the positive measure defined by
\[ MA(f) = (dd^# f)^n := dd^# f \wedge ... \wedge dd^# f, \]
where the product is taken $n$ times.

Note that we here identify closed, positive $(n, n)$—currents with positive measures. If $f$ is smooth, then
\[ MA(f) = det( \frac{\partial^2 f}{\partial x_i \partial x_j}) dx_1 \wedge d\xi_1 \wedge ... \wedge dx_n \wedge d\xi_n. \]

A very nice paper concerning real Monge-Ampère measures is [11]. In fact, our approach in this paper could be considered as a generalization of the formalism defined there in.

Proposition 2.10. Let $f$ be a convex, 1—homogeneous function, that is, $f(\lambda x) = \lambda f(x)$ for every $x \in \mathbb{V}$ and $\lambda \in \mathbb{R}$. Then $MA(f) = 0$ at every point $x \neq 0$.

Proof. Assume first that $f$ is smooth and fix a point $x \neq 0$. The homogeneity of $f$ implies that there exists a direction in which $f$ is affine. More precisely, there exists a linear subspace of dimension 1, such that the restriction of $f$ to this subspace is piecewise affine, the two pieces being separated by the origin. By an affine change of coordinates we can thus assume that $\frac{\partial^2 f}{\partial x_1 \partial x_1} (x) = 0$, that is, one of the eigenvalues of $D^2 f(x)$ vanishes. This implies that $MA(f)(x) = 0$. If $f$ is not assumed to be smooth, we choose a family of 1-homogeneous smooth convex functions such that $f_i \to f$. By continuity of the Monge-Ampère operator, $MA(f) = \lim_{i \to \infty} MA(f_i) = 0$. \qed

Example 2.11. We wish to calculate the Monge-Ampère measure of $dd^# |x|$. First we calculate
\[(2.6) \quad dd^# |x| = d\left( \frac{1}{2|x|}d^# (|x|^2) \right) = \frac{dd^# |x|^2}{2|x|} - \frac{d|x|^2 \wedge d^# |x|^2}{4|x|^3}. \]

But the form $\frac{d|x|^2 \wedge d^# |x|^2}{4|x|^3} = 0$ on $|x| = r > 0$ and so, by using Stokes’ theorem, we obtain
\[ \int_{B(0, r) \times \mathbb{R}^n} (dd^# |x|)^n = \int_{\partial B(0, r) \times \mathbb{R}^n} \frac{d^# |x| \wedge (dd^# |x|^2)^{n-1}}{2^n |x|^n} = \]
\[ = \frac{1}{2^n r^n} \int_{B(0, r) \times \mathbb{R}^n} \left( \sum_k 2 dx_k \wedge d\xi_k \right)^n = \frac{n!}{r^n} \int_{B(0, r) \times \mathbb{R}^n} dx_1 \wedge d\xi_1 \wedge ... \wedge dx_n \wedge d\xi_n = \]
\[ = n! Vol_n(B(0, 1)). \]
Since the above integral is independent of $r$ (or by using proposition 2.10, we see that the measure $(dd^# |x|)^n$ equals the Dirac measure at the origin multiplied with a dimensional constant.

A useful class of convex functions are those that grow “at most linearly at infinity”. By the similarity with the complex setting, we define the Lelong class to be the class of such functions:
\[(2.7) \quad \mathcal{L} = \{ f : \mathbb{R}^n \to \mathbb{R} : f(x) \leq C|x| + D, f \text{ convex}, C \geq 0, D \in \mathbb{R} \} . \]
This class is useful in our context since the intersection of currents whose potentials belongs to $\mathcal{L}$ has finite total mass. To see this, we first consider the case of the Monge-Ampère measure of functions in $\mathcal{L}$:

**Proposition 2.12.** Let $f \in \mathcal{L}$ so that we can find a constant $c > 0$ for which $f \leq c|x|$, when $|x|$ is sufficiently large. Then $f$ satisfies

$$\int_{\mathbb{R}^n \times \mathbb{R}^n} (dd^# f)^n < +\infty.$$  

**Proof.** Fix $\epsilon > 0$. For every $r > 0$ we can find a constant $D > 0$ such that $f \geq -D + (c + \epsilon)|x|$, if $|x| < r$ but $f \leq -D + (c + \epsilon)|x|$, if $|x| > R$, for $R$ sufficiently large. Denote by $H$ the function $\max\{f, -D + (c + \epsilon)|x|\}$. Then $H$ is convex, and so $dd^# H \geq 0$. We can exploit this as follows:

$$\int_{B(0,r) \times \mathbb{R}^n} (dd^# f)^n = \int_{B(0,r) \times \mathbb{R}^n} (dd^# H)^n \leq \int_{B(0,R) \times \mathbb{R}^n} (dd^# H)^n =$$

$$= \int_{\partial B(0,R) \times \mathbb{R}^n} d^# (-D + (c + \epsilon)|x|) \wedge (dd^# (-D + (c + \epsilon)|x|))^{-1} =$$

$$= \int_{B(0,R) \times \mathbb{R}^n} (dd^# (-D + (c + \epsilon)|x|))^{n-1} \leq (c + \epsilon)^n \int_{\mathbb{R}^n \times \mathbb{R}^n} (dd^# |x|)^n < +\infty.$$  

Letting $r \to \infty$ we obtain

$$\int_{\mathbb{R}^n \times \mathbb{R}^n} (dd^# f)^n < +\infty.$$

\qed

**Proposition 2.13.** If $f_1, \ldots, f_n \in \mathcal{L}$, then

$$\int_{\mathbb{R}^n \times \mathbb{R}^n} dd^# f_1 \wedge \ldots \wedge dd^# f_n < +\infty.$$  

**Proof.** Since $f_1 + \ldots + f_n \in \mathcal{L}$ there exists a $C > 0$ such that $f_1 + \ldots + f_n \leq C|x|$, when $|x|$ is large enough. By proposition 2.12, with $f = f_1 + \ldots + f_n$, we obtain

$$\int_{\mathbb{R}^n \times \mathbb{R}^n} (dd^# f_1 + \ldots + dd^# f_n)^n < +\infty.$$  

But $(dd^# f_1 + \ldots + dd^# f_n)^n$ is a sum with one term equal to $dd^# f_1 \wedge \ldots \wedge dd^# f_n$, and since every term of the sum is a positive measure, we deduce that

$$\int_{\mathbb{R}^n \times \mathbb{R}^n} dd^# f_1 \wedge \ldots \wedge dd^# f_n < +\infty,$$

which concludes the proof. \qed

A slight modification of the proof of the above Proposition 2.12 gives us a useful comparison theorem, whose analogue in the complex setting is well known.

**Proposition 2.14.** Let $f, g \in \mathcal{L}$ be such that $f \leq g + O(1)$. Then

$$\int_{\mathbb{R}^n \times \mathbb{R}^n} (dd^# f)^n \leq \int_{\mathbb{R}^n \times \mathbb{R}^n} (dd^# g)^n.$$
Proof. Fix $\epsilon > 0$. For every $r > 0$ we can find a constant $D > 0$ such that $f \geq -D + g + \epsilon|x|$, if $|x| < r$ but $f \leq -D + g + \epsilon|x|$, if $|x| > R$, for $R$ sufficiently large. Denote by $H$ the function $\max\{f, -D + g + \epsilon|x|\}$. Then $H$ is convex, and so $dd^c H \geq 0$. As before:

$$\int_{B(0,r) \times \mathbb{R}^n} (dd^c f)^n = \int_{B(0,R) \times \mathbb{R}^n} (dd^c H)^n \leq \int_{B(0,R) \times \mathbb{R}^n} (dd^c H)^n =$$

$$= \int_{B(0,R) \times \mathbb{R}^n} (dd^c (-D + g + \epsilon|x|))^n \leq \int_{\mathbb{R}^n \times \mathbb{R}^n} (dd^c g + \epsilon dd^c |x|)^n.$$

Letting $r \to \infty$ we obtain that, for every $\epsilon > 0$,

$$\int_{\mathbb{R}^n \times \mathbb{R}^n} (dd^c f)^n \leq \int_{\mathbb{R}^n \times \mathbb{R}^n} (dd^c g + \epsilon dd^c |x|)^n.$$

This last integral contains terms of the type $(dd^c g)^{n-k} \wedge \epsilon^k (dd^c |x|)^k$ with $k = 0, \ldots, n$. If $k \neq n$, proposition 2.13 tells us that

$$\int_{\mathbb{R}^n \times \mathbb{R}^n} (dd^c g)^{n-k} \wedge \epsilon^k (dd^c |x|)^k \leq C_k \epsilon^k$$

and consequently there is a constant $C > 0$ (independent of $\epsilon$) for which

$$\int_{\mathbb{R}^n \times \mathbb{R}^n} (dd^c g + \epsilon dd^c |x|)^n \leq \int_{\mathbb{R}^n \times \mathbb{R}^n} (dd^c g)^n + C.$$

Letting $\epsilon \to 0$ completes the proof. \hfill $\square$

Interchanging the roles of $f$ and $g$ in the above proposition gives us:

**Corollary 2.15.** If $f, g \in \mathcal{L}$ satisfy

$$|f - g| \leq C,$$

for some constant $C > 0$, then

$$\int_{\mathbb{R}^n \times \mathbb{R}^n} (dd^c f)^n = \int_{\mathbb{R}^n \times \mathbb{R}^n} (dd^c g)^n.$$

In fact, the proof gives us a slightly stronger statement, which we will find useful:

**Corollary 2.16.** If $f, g \in \mathcal{L}$ satisfy

$$|f - g| \leq C + \epsilon|x|$$

for every $\epsilon > 0$ and for some constant $C > 0$, then

$$\int_{\mathbb{R}^n \times \mathbb{R}^n} (dd^c f)^n = \int_{\mathbb{R}^n \times \mathbb{R}^n} (dd^c g)^n.$$

**Example 2.17.** Let $K \subset \mathbb{R}^n$ be a convex set containing the origin, and denote by $H_K$ its support function, that is, $H_K(x) = \sup_{\xi \in K} \{x \cdot \xi\}$. The polar of $K$, denoted $K^\circ$, is defined by $K^\circ = \{x : H_K(x) \leq 1\}$. If $\partial K$ is smooth and $K$ strictly convex, it is well known that the map $x \mapsto \partial H_K(x)$ defines a diffeomorphism between $\partial K$ and $\partial K^\circ$. We can thus introduce $\frac{\partial H_K}{\partial x_i}$ as coordinates on $\partial K^\circ$ to obtain

$$n! Vol(K) = \int_{K \times \mathbb{R}^n} (dd^c |x|^2)^n = \int_{\partial K \times \mathbb{R}^n} d^c |x|^2 \wedge (dd^c |x|^2)^{n-1} =$$

$$= c_n \int_{\partial K} \sum x_i d\bar{x}_i = c_n \int_{\partial K^\circ} \sum \frac{\partial H_K}{\partial x_i} \cdot d\frac{\partial H_K}{\partial x_i} = \int_{K^\circ \times \mathbb{R}^n} d^c H_K \wedge (dd^c H_K)^{n-1} =$$
\[(2.8) \quad M\simeq (\partial K)^n = (\partial H_K)^n.\]

In the last equality we used proposition 2.10 since \(H_K\) is smooth outside the origin (thanks to \(\partial K\) being smooth) and 1-homogeneous, the support of \((d\delta^n H_K)^n\) is the origin. By approximation, the same formula holds without any smoothness assumptions on \(\partial K\).

One can generalize this example as follows: Recall that if \(K_1, \ldots, K_n\) are convex sets in \(\mathbb{R}^n\) one can define the mixed volume of \(K_1, \ldots, K_n\), which we will denote by \(V(K_1, \ldots, K_n)\) as follows: consider the function

\[P(t_1, \ldots, t_n) := Vol(t_1K_1 + \ldots + t_nK_n),\]

where

\[\sum_{j \in J} t_j K_j := \{t_{j_1} \cdot x_{j_1} + \ldots + t_{j_j} \cdot x_{j_j} : x_{j_i} \in K_{j_i}, J = (j_1, \ldots, j_j)\}\]

is the Minkowski sum. As will follow from the proof of Proposition 2.18, \(P\) is a \(n\)-homogeneous polynomial in \(n\) variables:

\[P(t_1, \ldots, t_n) = \sum_{i_1, \ldots, i_n = 1}^n a_{i_1, \ldots, i_n} t_{i_1} \cdot \ldots \cdot t_{i_n},\]

for some coefficients \(a_{i_1, \ldots, i_n}\). The mixed volume is the coefficient in this polynomial corresponding to the monomial \(t_1 \cdot \ldots \cdot t_n\), that is,

\[V(K_1, \ldots, K_n) := a_{1, \ldots, n}.\]

We claim the following:

**Proposition 2.18.** Let \(K_1, \ldots, K_n\) be convex sets in \(\mathbb{R}^n\) with corresponding support functions \(H_{K_i}\). Then

\[dd\delta H_{K_1} \wedge \ldots \wedge dd\delta H_{K_n} = n! \cdot V(K_1, \ldots, K_n) \delta_0 \omega_n,\]

and \(P(t_1, \ldots, t_n) := Vol(t_1K_1 + \ldots + t_nK_n)\) is a \(n\)-homogeneous polynomial.

**Proof.** To begin with, we note that

\[(2.9) \quad H_{tK+sL}(x) = tH_{tK} + sH_L\]

if \(K, L\) are compact subsets, and \(t, s\) real numbers. This is justified by the following equalities:

\[H_{tK+sL}(x) = \sup_{\xi = \xi_1 + \xi_2 \in K + sL} \{t\xi \cdot x + s\xi \cdot x\} = \sup_{\xi \in K, \xi \in L} \{t\xi_1 \cdot x + s\xi_2 \cdot x\} = tH_K(x) + sH_L(x).\]

Generalizing this slightly, we obtain the identity

\[MA(H_{t_1K_1+\ldots+t_nK_n}) = MA(t_1H_{K_1} + \ldots + t_nH_{K_n}),\]

and thus \(MA(H_{t_1K_1+\ldots+t_nK_n})\) is a \(n\)-homogeneous polynomial in \((t_1, \ldots, t_n)\). Moreover, by (2.3) we know that

\[MA(H_{t_1K_1+\ldots+t_nK_n}) = n!Vol(t_1K_1 + \ldots + t_nK_n) \cdot \delta_0 \cdot \omega_n.\]
This immediately gives us that 
\[ P(t_1, \ldots, t_n) = Vol(t_1K_1 + \ldots + t_nK_n) \]
is an \( n \)-homogeneous polynomial. Moreover, comparing coefficients of the two polynomials, we see that 
\[ dd^\#: H_{K_1} \wedge \ldots \wedge dd^\#: H_{K_n} = n! \cdot V(K_1, \ldots, K_n) \cdot \delta_0 \cdot \omega_n \]
as desired. \( \square \)

**Remark 2.19.** These results should be compared with the results already obtained in [9].

Let \( f \) be a convex function on \( \mathbb{R}^n \), belonging to the Lelong class \( \mathcal{L} \). To this \( f \) we associate the function 
\[ \tilde{f}(x) = \lim_{t \to \infty} \frac{f(tx)}{t}, \]
where the limits exists thanks to the assumption on linear growth at infinity. This function \( \tilde{f} \) is easily seen to be convex and one-homogeneous. Moreover, we claim that
\[ |f - \tilde{f}| \leq C + \epsilon |x|, \]
for every \( \epsilon > 0 \). This is readily seen as follows: By standard properties of convex functions, the expression \( \frac{f(tx) - f(0)}{t} \) is increasing in \( t \), for every \( x \). We recall Dini’s theorem which says the following: if \( f \) is continuous on a compact set \( K \), and \( f_t \) is a monotone sequence of continuous functions which converge to \( \tilde{f} \) pointwise, then the convergence is in fact uniform on \( K \). Consequently, for each \( \epsilon > 0 \) we have that
\[ \sup_{|x|=1} \left| \frac{f(tx) - f(0)}{t} - \tilde{f}(x) \right| < \epsilon, \]
if \( t > T \), for some \( T > 0 \). Multiplying through by \( t \) we obtain
\[ \sup_{|x|=1} |f(tx) - f(0) - \tilde{f}(tx)| < t\epsilon, \]
if \( t \) is sufficiently large, which implies (2.10). An application of Corollary 2.16 shows that the total Monge-Ampère mass of \( f \) equals that of \( \tilde{f} \):

**Proposition 2.20.** With \( f \) and \( \tilde{f} \) as above
\[ \int_{\mathbb{R}^n \times \mathbb{R}^n} (dd^\# f)^n = \int_{\mathbb{R}^n \times \mathbb{R}^n} (dd^\# \tilde{f})^n. \]

As we will see in Section 4.3, the above Proposition is essentially Bezout’s theorem in tropical geometry.

3. LELONG NUMBERS, TRACE MEASURES AND PUSH FORWARDS OF CURRENTS.

**Definition 3.1.** The trace measure of a \((p,p)\)-current \( T \) is defined as
\[ \Theta_T(U) = \frac{1}{2^{n-p}(n-p)!} \int_{U \times \mathbb{R}^n} T \wedge (dd^\# |x|^2)^{n-p}, \]
for each Borel-set \( U \subset \mathbb{R}^n \).

**Proposition 3.2.** If \( T \) is a positive \((p,p)\)-current, then \( \Theta_T \) is a positive measure, and
\[ |T_{IJ}| \leq C \cdot \Theta_T, \]
for some \( C > 0 \).
Proof. This follows immediately from Proposition \[\text{2.2}\]. \qed

Remark 3.3. Let us compare with the complex setting: if $S$ is a complex, weakly positive $(p,p)$-current, then $S$ always satisfies a trace measure inequality of the type (3.1). However, in our setting the form $\alpha$ implies a significant difference between our setting and the complex setting. In fact, in the complex case, the strongly positive forms constitute a basis for the space of all forms. Equation (3.2) tells us that this is not the case in our setting.

Proposition 3.4. For fixed $x \in \mathbb{R}^n$, if $T$ is a weakly positive $(p,p)$-current, then the function

$$r \mapsto \frac{\Theta_T}{r^{n-p}}(B(x,r))$$

is increasing on $\mathbb{R}_+$. 

Proof. We can assume that $x = 0$. By equation (2.6) we have,

$$dd^\#|x| = \frac{dd^\#|x|^2}{2|x|} = \frac{d|x|^2 \wedge d^\#|x|^2}{4|x|^2},$$

and $\frac{d|x|^2 \wedge d^\#|x|^2}{4|x|^3} = 0$ on the sphere $|x| = r$. Moreover, $d^\#|x| = \frac{d^\#|x|^2}{2|x|}$, so that $d^\#|x| = \frac{d^\#|x|^2}{2r}$ if $|x| = r$. Combining these observations, we find that

$$\int_{\{|x|=r\} \times \mathbb{R}^n} T \wedge d^\#|x| \wedge (dd^\#|x|)^{n-p} - 1 = \int_{\{|x|=r\} \times \mathbb{R}^n} T \wedge \frac{d|x|^2}{2|x|} \wedge (dd^\#|x|^2)^{n-p-1} =$$

$$= \frac{1}{(2r)^{n-p}} \int_{\{|x|=r\} \times \mathbb{R}^n} T \wedge d^\#|x|^2 \wedge (dd^\#|x|^2)^{n-p-1}.$$

Thus, by Stokes' theorem we obtain

$$\int_{B(0,r) \times \mathbb{R}^n} T \wedge (dd^\#|x|^2)^{n-p} = \int_{\{|x|=r\} \times \mathbb{R}^n} T \wedge d^\#|x|^2 \wedge (dd^\#|x|^2)^{n-p-1} =$$

$$(2r)^{n-p} \int_{\{|x|=r\} \times \mathbb{R}^n} T \wedge d^\#|x| \wedge (dd^\#|x|^2)^{n-p-1} =$$

$$= (2r)^{n-p} \int_{B(0,r) \times \mathbb{R}^n} T \wedge (dd^\#|x|)^{n-p}.$$
Corollary 3.5. Let $T$ be a closed, positive $(p,p)$–current. If $K$ is a compact set with vanishing $(n − p)$–dimensional Hausdorff measure, then $T$ vanishes on $K$. In particular, if $\text{Supp}(T)$ has vanishing $(n − p)$–dimensional Hausdorff measure, then $T = 0$.

Proof. Let $K$ be a compact set, satisfying the assumptions of the hypothesis. The condition $\mathcal{H}^{n-p}(K) = 0$, means that we can, for every $\epsilon > 0$, find a finite number of balls $B(a_j, r_j)$ for which $K \subset \bigcup_j B(a_j, r_j)$ and

$$\sum r_j^{n-p} \leq \epsilon.$$ 

We can assume that each $r_j \leq 1$. By Proposition 3.3 we see that

$$\frac{\Theta_T}{r_j^{n-p}}(B(a_j, r_j)) \leq \Theta_T(B(a_j, 1)) \leq \Theta_T(K'),$$

where $K'$ is a compact set such that $K \subset \bigcup_j B(a_j, 1) \subset K'$ and thus, with $C = \Theta_T(K')$ we obtain the inequality: $\Theta_T(B(a_j, r_j)) \leq Cr_j^{n-p}$ for all $j$. We conclude that

$$\Theta_T(K) \leq \sum_j \Theta_T((B(a_j, r_j)) \leq C \sum_j r_j^{n-p} \leq C\epsilon,$$

and thus, $T|_K = 0$, since $|T_j|\big(K\big) \leq \Theta_T(K)$ by Proposition 3.2.

As a consequence of the proposition, we can define the Lelong number of a weakly positive, closed $(p,p)$–current $T$ at a point $x$ by

$$\nu_x(T) = \lim_{r \to 0} \frac{\Theta_T(B(x, r))}{Vol(B^{n-p})r^{n-p}},$$

where $Vol(B^{n-p})$ is the volume of the $(n − p)$–dimensional unit ball. We define the Lelong number of a convex function $f : \mathbb{R}^n \to \mathbb{R}$ by

$$\nu_x(f) = \nu_x(dd^c f).$$

Example 3.6. We calculate the Lelong number of the function $x \mapsto |x|$. We begin with considering the behaviour at the origin. By (2.0) and Stokes’,

$$\int_{B(0,r) \times \mathbb{R}^n} dd^c |x| \wedge (dd^c |x|^2)^{n-1} =$$

$$= \frac{1}{2r} \int_{B(0,r) \times \mathbb{R}^n} (dd^c |x|^2)^n = 2^{n-1} \cdot n! \cdot r^{n-1} \cdot Vol_n(B(0,1)),$$

and thus

$$\nu_0(|x|) = \lim_{r \to 0} \frac{\Theta(B(0,r))}{Vol_{n-1}(B(0,r))} = n \cdot \frac{Vol_n(B(0,1))}{Vol_{n-1}(B(0,1))}.$$

On the other hand, at a point $x_0$ away from the origin our function is smooth, and so the form $dd^c |x|$ is locally smooth. But if $g$ is a smooth function in a neighbourhood around $x$, then the trace measure of $dd^c g(x)$ is just the Laplacian of $g$ at $x$ and thus there is a constant $C > 0$ such that

$$\Theta_{dd^c g}(B(x, r)) \leq Cr^n,$$

since every coefficient $\frac{\partial^2 g}{\partial x_i \partial x_j}$ is uniformly bounded in some neighbourhood around $x$. Thus

$$\nu_x(g) \leq \lim_{r \to 0} \frac{Cr^n}{r^{n-1}Vol_{n-1}(B(0,1))} = 0,$$
and so $\nu_x(|x|) = 0$ if $x_0 \neq 0$.

The above argument displays the following expected behaviour of the Lelong number, showing that the Lelong number is a measurement of the singularity at a point:

**Proposition 3.7.** If a $(1,1)$–current $T$ is locally smooth around a point $x$, then $\nu(T,x) = 0$.

**Remark 3.8.** In complex analysis, it is a well known theorem due to Y.T. Siu, which states that the set $\{x : \nu(T,x) \geq c\}$ constitutes an analytic variety, for each $c > 0$ (in this remark, $\nu(T,x)$ denotes the complex version of the Lelong number). It would be interesting to know if there is a corresponding result in our setting. One could perhaps hope that one would obtain tropical varieties (which we define in Section 4), but this is not the case as the example $f = \max(|x|,1)$ shows: 

$\{x \in \mathbb{V} : \nu(dd^\# \max(|x|,1),x) \geq c\} = \{x : |x| = 1\}$ which is not a tropical variety.

### 3.1. Push forwards of currents.

Let $f : \mathbb{V} \to \mathbb{V}'$ be an affine map, with $\dim(\mathbb{V}) = \dim(\mathbb{V}') = n$, inducing a map $\tilde{f} : \mathbb{E} \to \mathbb{E}'$. Then we can define the push-forward $f_*T$ of a current $T \in \mathcal{D}_{n-p,n-p}(\mathbb{E})$ via the formula

$$
(f_*T, \alpha) = (T, f^*\alpha),
$$

where $\alpha \in \mathcal{D}^{p,p}$. This formula only makes sense if $f^*\alpha$ has compact support on $\text{Supp}(T)$, and so we first demand that $f$ is such that $f^{-1}(K) \cap \text{Supp}(T)$ is compact for every compact $K \subset \mathbb{V}'$, or in other words, the restriction of $f$ to $\text{Supp}(T)$ is proper. For such $f$ the induced map $f^* : \mathcal{E}^{p,p}(\mathbb{E}') \to \mathcal{E}^{p,p}(\mathbb{E})$ is continuous and thus the above formula defines an element in $\mathcal{D}_{n-p,n-p}(\mathbb{E}')$. If $T$ is weakly positive, then

$$
(f_*T, \alpha_1 \wedge J(\alpha_1) \wedge ... \wedge \alpha_p \wedge J(\alpha_p)) = (T, f^*\alpha_1 \wedge J(f^*\alpha_1) \wedge ... \wedge f^*\alpha_p \wedge J(f^*\alpha_p)) \geq 0.
$$

Thus we have the following proposition.

**Proposition 3.9.** If $T \in \mathcal{D}_{n-p,n-p}(\mathbb{E})$ is weakly positive and $f : \mathbb{V} \to \mathbb{V}'$ is an (non-constant) affine function, then $\tilde{f}_*T$ is a weakly positive current in $\mathcal{D}_{n-p,n-p}(\mathbb{E}')$.

**Example 3.10.** Every form $\beta \in \mathcal{E}^{p,p}$ can be considered as a current acting on compactly supported forms of complementary degree. Now, if $f : \mathbb{V} \to \mathbb{V}$ is a non-singular affine map, then

$$
(f_*\beta) = (f^*\alpha, \beta) = \int_E f^*\alpha \wedge \beta = \frac{1}{|\text{det}(f^-1)|} \int_E (f^-1)^*(f^*\alpha \wedge \beta) = |\text{det}(f)| \int_E \alpha \wedge (f^{-1})^*\beta = |\text{det}(f)| \langle \alpha, (f^{-1})^*\beta \rangle,
$$

where we used formula (1.4) in the third equality. Thus we see that,

$$
(f_*\beta) = |\text{det}(f)| (f^-1)^*\beta, \beta \in \mathcal{E}^{p,p}.
$$

Now let us consider the projection (here we write $\mathbb{V}, \mathbb{W} = \mathbb{R}^n$)

$$
\pi : \mathbb{R}^n \to \mathbb{R}^{n-k}, \pi(x_1, ..., x_n) = (x_1, ..., x_{n-k}),
$$

where $k \geq 0$ and take a $(p,p)$–form $\alpha$ on $\mathbb{R}^n$, with locally integrable coefficients, which we will consider as a current. Assume this form $\alpha$ is such that $\pi$ is proper on its support, and let $\omega$ be a $(n-p,n-p)$–form on $\mathbb{R}^{n-k} = \{(x_1, ..., x_{n-k})\}$.
Observe that if $n - p > n - k$, the form $\omega$ is 0, so we assume this is not the case. We regard, for each $x \in \mathbb{R}^{n-k}$, the set $\pi^{-1}(x)$ as $\mathbb{R}^k$ with coordinates $(x_{n-k+1}, \ldots, x_n)$. Thus $\omega$ only contains differentials $dx_i$ and $d\xi_i$ with $1 \leq i \leq n - k$, and $\pi^*\omega = \omega$.

Let us write $\alpha = \sum_{|I| = |J| = p} \alpha_{IJ} dx_I \wedge d\xi_J$, and $\omega = \sum_{|K| = |L| = n-p} \omega_{KL} dx_K \wedge d\xi_L$ where each $K$ and $L$ only contain indices between 1 and $n - k$. The $(n,n)$-form $\alpha \wedge \pi^*\omega$ is a sum of terms of the form $\alpha_{IJ} \omega_{KL} dx_I \wedge d\xi_J \wedge dx_K \wedge d\xi_L$ and such a term vanishes if $I$ and $K$, or if $J$ and $L$, contain the same indices. Since $n - p \leq n - k$, this implies that the only terms in the expression defining $\alpha$ that will contribute to the push-forward are those for which $dx_I \wedge d\xi_J$ contains the differential $dx_{n-k+1} \wedge \ldots \wedge dx_n \wedge d\xi_{n-k+1} \wedge \ldots \wedge d\xi_n$. In effect, we can write $\alpha$ as

$$\alpha = \left\{ \sum_{|I| = |J| = p-k} \alpha_{IJ} dx_I \wedge d\xi_J \right\} \wedge dx_{n-k+1} \wedge \ldots \wedge dx_n \wedge d\xi_{n-k+1} \wedge \ldots \wedge d\xi_n + R,$$

where $R$ is such that $R \wedge \omega' = 0$ for every $(n - p, n - p)$-form $\omega'$ on $\mathbb{R}^{n-k}$, and hence will not contribute to the push forward. The definition of push-forward tells us that

$$\langle \pi_* \alpha, \omega \rangle = \langle \alpha, \pi^* \omega \rangle = \int_{\mathbb{R}^n} \int_{(x_1, \ldots, x_{n-k}) \in \mathbb{R}^{n-k}} \int_{(x_{n-k+1}, \ldots, x_n) \in \pi^{-1}(x)} \alpha(x_1, \ldots, x_n) \wedge \omega(x_1, \ldots, x_{n-k}),$$

and from this we deduce that the push forward of $\alpha$ under $\pi$ is given by the $(p-k, p-k)$-form

$$\langle \pi_* \alpha \rangle(x_1, \ldots, x_{n-k}) = \int_{\pi^{-1}(x_1, \ldots, x_{n-k}) \times \mathbb{R}^n} \left\{ \sum_{|I'| = |J'| = p-k} \alpha_{IJ} dx_I \wedge d\xi_J \right\} \wedge dx_{n-k+1} \wedge \ldots \wedge dx_n = \sum_{|I'| = |J'| = p-k} \tilde{\alpha}_{IJ} dx_{I'} \wedge d\xi_{J'},$$

where

$$\tilde{\alpha}_{IJ}(x_1, \ldots, x_{n-k}) = \int_{\pi^{-1}(x_1, \ldots, x_{n-k})} \alpha_{IJ}(x_1, \ldots, x_n) dV_k(x_{n-k+1}, \ldots, x_n)$$

and $dV_k$ is the volume measure induced by the chosen inner product on $\mathbb{R}^n$. We have hence obtained an explicit formula for the push-forward of a form $\alpha$ under a projection. By using an approximation argument, the discussion above still holds true if we assume $\alpha$ to be a strongly positive current. Now, since $\pi^*d\omega = d\pi^*\omega$, we see that

$$\langle d\pi_* \alpha, \omega \rangle = \pm \langle \pi_* \alpha, d\omega \rangle = \pm \langle \alpha, \pi^* d\omega \rangle = \pm \langle \pi_* d\alpha, \omega \rangle = \langle \pi_* d\alpha, \omega \rangle,$$

which implies that $\pi_* d\alpha = d\pi_* \alpha$. Thus, if $\alpha$ is closed, then $\pi_* \alpha$ is closed as well. Since strong positivity of forms is preserved under pullbacks, we find that if $\alpha$ is a weakly positive form, then $\pi_* \alpha$ is weakly positive. Moreover, the formula

$$\langle f_* \alpha, \sigma_{(n-k)-(p-k)} \beta \wedge J(\beta) \rangle = \langle \alpha, \sigma_{n-p} f^* \beta \wedge J(f^* \beta) \rangle,$$

tells us that if $\alpha$ is positive, then so is $f_* \alpha$. Thus we have:

**Proposition 3.11.** Let $\pi$ be a projection from $\mathbb{R}^n$ onto a $(n - k)$-dimensional subspace, and let $\alpha$ be a (weakly) positive $(p,p)$-current on $\mathbb{R}^n \times \mathbb{R}^n$ such that $\pi$ is proper on the support of $\alpha$. Then the push-forward $\pi_* \alpha$ is a well-defined $(p-k, p-k)$-current. Moreover, $\pi_* \alpha$ is (weakly) positive, and if $\alpha$ is closed then $\pi_* \alpha$ is closed as well.
Now let $f_1, f_2, ..., f_p \in \mathcal{L}$ and let $S = dd^\# f_1 \wedge ... \wedge dd^\# f_p$. Let $\pi$ be a projection from $\mathbb{R}^n$ onto a $(n-k)$-dimensional subspace $L$ as above. Since the restriction of $\pi$ to $\text{Supp}(S)$ might not be proper, the expression $\pi_* S$ has no meaning as of yet. However, if $\chi$ is a continuous function with compact support on $\pi^{-1}(L)$ and with values in $[0, 1]$, we can consider the positive (but not closed) current $\pi_* \chi S$ on $L$. We have the following lemma:

**Lemma 3.12.** For every compact subset $K \subset L$ there exists a constant $C_K > 0$ which is independent of $\chi$, such that the measure-coefficients of $\pi_* \chi S$ applied to $K$ are bounded by $C_K$.

*Proof.* We choose coordinates so that $L = \mathbb{R}^{n-k}$ as above and write $x' = (x_1, ..., x_{n-k})$. It is enough to prove that the statement holds for every ball with center at the origin, in $\mathbb{R}^{n-k}$. Fix such a ball $B(0, R)$. Define a function $\phi$ on $\mathbb{R}^{n-k}$ by letting $\phi(x') = |x'|^2$ for $x' \in B(0, 2R)$, and $\phi(x') = 4R|x'| - 4R^2$ otherwise. Then $\phi \in \mathcal{L}$, and $dd^\# \phi = \sum_{i=1}^{n-k} dx_i \wedge dx_i$ on $B(0, R)$. Thus, $(dd^\# \phi)^{n-p} = (dd^\# |x'|^2)^{n-p}$ on $B(0, R)$, which implies that

$$\Theta_{B(0, R)}(\pi_* \chi S) = \int_{B(0,R) \times \mathbb{R}^k} \chi S \wedge (dd^\# |x'|^2)^{n-p} = \int_{B(0,R) \times \mathbb{R}^k} \chi S \wedge (dd^\# \phi)^{n-p} \leq \sup \chi \int_{\mathbb{R}^n \times \mathbb{R}^n} S \wedge (dd^\# \phi)^{n-p}.$$  

By Proposition 2.13 the right hand side is finite. Since $\pi_* \chi S$ is positive, we can apply Proposition 3.2 to obtain that every coefficient of $\pi_* \chi S$ applied to $B(0, R)$ has mass bounded by the trace-measure of $\chi \pi_* S$ acting on $B(0, R)$ and is consequently less than some constant $C_R > 0$ depending on $R$ (since $\phi$ depends on $R$) but not on $\chi$. The proposition follows. $\square$

Assume that the functions $f_i$ are smooth. Then Lemma 3.12 together with (3.5) tells us that there is a constant $C > 0$ such that for every positive, compactly supported, continuous function $\chi$ defined on $\pi^{-1}(L) = \mathbb{R}^k$ with values in $[0, 1]$, the following inequality holds:

$$\left| \int_{\pi^{-1}(x_1, ..., x_{n-k})} \chi(x_{n-k+1}, ..., x_n) S_{I', J'}(x_1, ..., x_n) dV_k(x_{n-k+1}, ..., x_n) \right| \leq C \cdot \text{Sup}(\chi).$$

This implies that all of the integrals

$$\int_{\pi^{-1}(x_1, ..., x_{n-k})} S_{I', J'}(x_1, ..., x_n) dV_k(x_{n-k+1}, ..., x_n)$$

converge. Thus, if we let $\chi_R$ be functions of the kind considered with the additional assumption that their support should exhaust $\pi^{-1}(L)$ as $R \to \infty$, we see that the weak limit of $\pi_* \chi_R S$ as $R \to \infty$ exists, and we put

$$
\pi_* dd^\# f_1 \wedge ... \wedge dd^\# f_p = \lim_{R \to \infty} \pi_* \chi_R S.
$$

It is easy to see that it does not depend on the choice of functions $\chi_R$, and if $\pi$ were to have proper support on $dd^\# f_1 \wedge ... \wedge dd^\# f_p$, this definition would coincide with the previous one given above. We want to show that this current is closed and positive. For this we construct explicit choices of $\chi_R$ as follows:
Let \( \tilde{\chi}_R : \mathbb{R}_+ \rightarrow \mathbb{R} \) be the piecewise linear function, equal to 1 on \([0, R]\), equal to 0 on \([2R, +\infty)\) and linear in between. Then \( \tilde{\chi}_R = R^{-1} \) on the interval \([R, 2R]\) and 0 otherwise. We now put \( \chi_R(x) = \tilde{\chi}_R(|x|) \).

**Proposition 3.13.** Let \( \pi : \mathbb{R}^n \rightarrow L \) be a projection, where \( L \) is a \((n-k)\)-dimensional subspace of \( \mathbb{R}^n \), and assume that \( f_1, f_2, \ldots, f_p \in L \). Then

\[
\langle \pi_* dd^\# f_1 \wedge \ldots \wedge dd^\# f_p \rangle
\]

is a well-defined positive, closed \((p-k, p-k)\)-current. If \( p < k \) then \( \pi_* dd^\# f_1 \wedge \ldots \wedge dd^\# f_p = 0 \).

**Proof.** We have yet to show that it is closed and positive. Let \( S = dd^\# f_1 \wedge \ldots \wedge dd^\# f_p \) as above. Positivity is clear, since, if \( \pi \in D^{n-p,0} \),

\[
\langle (\pi_* S), \sigma (n-k) (p-k) \alpha \wedge J(\alpha) \rangle = \lim_{R \rightarrow \infty} \int_E \chi_R S \wedge \sigma_{n-p} \cdot \pi^* \alpha \wedge \pi^* J(\alpha) \geq 0,
\]

by the positivity of \( S \). To prove closedness, we use the specific function \( \chi_R \) constructed above. Then, for \( \alpha \in D^{n-p-1,n-p}(L) \),

\[
\langle \pi_* S, \alpha \rangle = \pm \lim_{R \rightarrow \infty} \int_E \chi_R \cdot S, \pi^* (da) \rangle = \lim_{R \rightarrow \infty} \langle d\chi_R \wedge S, \pi^* \alpha \rangle
\]

thanks to \( S \) being closed. We need to show that \( \lim_{R \rightarrow \infty} \langle d\chi_R \wedge S, \pi^* \alpha \rangle = 0 \). To this end we define the following bi-linear form:

\[
(v, w) = \int_E S \wedge \sigma_{n-p} v \wedge J(w),
\]

where \( v, w \) are compactly supported, smooth \((n-p, 0)\)-forms on \( \mathbb{R}^n \). Clearly \((v, v) \geq 0 \), since \( S \) is positive, and thus the bi-linear form is positive definite. A variant of the Cauchy-Schwartz inequality tells us that for each \( \epsilon > 0 \),

\[
(v, w) \leq \epsilon (v, v) + \epsilon^{-1} (w, w).
\]

Let us define, for each \( R > 0 \),

\[
\psi_R(t) = \begin{cases} 
\frac{R}{2} t - \frac{1}{2}, & \text{if } t \in [0, R) \\
\frac{t^2}{2R^2}, & \text{if } t \in [R, 2R] \\
\frac{1}{2} t - 6, & \text{if } t \in (2R, \infty)
\end{cases}
\]

Then \( \psi_R \) is convex, \( \psi_R(|x|) \in \mathcal{L} \), and \( \psi_R''(t) = 1/R^2 \) if \( t \in [R, 2R] \) and 0 otherwise. Moreover, a direct calculation shows that

\[
dd^\# \psi_R - d\chi_R \wedge dd^\# \chi_R \geq 0.
\]

Let \( v \) be a \((n-p-1, 0)\)-form, and \( w \) a \((0, n-p)\)-form defined on \( \mathbb{R}^{n-k} \), both smooth and with compact support. Then

\[
| \langle d\chi_R \wedge S, \pi^* v \wedge \pi^* w \rangle | = | \int_E S \wedge d\chi_R \wedge \pi^* v \wedge \pi^* w | = | \langle d\chi_R \wedge \pi^* v, \pi^* w \rangle |
\]

which by \((3.6)\) is dominated by

\[
\epsilon \int_E S \wedge \pi^* w \wedge J(\pi^* v) + \epsilon^{-1} \int_E S \wedge d\chi_R \wedge \pi^* v \wedge J(d\chi_R \wedge \pi^* v) = I + II.
\]

Here the form \( \pi^* w \) will not have compact support on \( \mathbb{R}^n \) so the first term actually has no meaning. However, we may here replace \( \pi^* w \) with \( \chi_{3R} \pi^* w \) which has compact support on \( \mathbb{R}^n \); doing so will not affect \((3.8)\), since \( \chi_{3R} = 1 \) on \( \text{Supp}(d\chi_R) \).
Using Lemma 3.12 we see that the first term, $I$, is bounded by $c C_w$. For the second term, $II$, we show that the trace measure of the strongly positive current, $S \wedge d\chi_R \wedge J(d\chi_R)$ tends to 0 as $R \to \infty$ : For each multi-index $I$ of length $n - p$, we can use the idea of Lemma 3.12 to find a function $\phi_I \in \mathcal{L}$, such that,

$$dd^\# \phi_I = dd^\# \sqrt{x_{i_1}^2 + \ldots + x_{i_{n-p}}^2} = dx_I \wedge d\xi_I,$$

on $B(0, 2R)$. Thus, since $S \wedge d\chi_R \wedge J(d\chi_R)$ is strongly positive,

$$|\int_{B(0, 2R) \times \mathbb{R}^n} S \wedge d\chi_R \wedge J(d\chi_R) \wedge dx_I \wedge d\xi_I| \leq |\int_{\mathbb{R}^n \times \mathbb{R}^n} S \wedge d\chi_R \wedge J(d\chi_R) \wedge dd^\# \phi_I|.$$

By (3.7) the last integral is dominated by

$$|\int_{\mathbb{R}^n} S \wedge dd^\# \psi_R \wedge dd^\# \phi_I|.$$

Thus, since $dd^\# \psi_R(|x|) = R^{-2} dd^\# |x|$ on $B(0, R)$ and zero otherwise, we obtain by Proposition 2.13 that

$$\epsilon^{-1} |\int_{B(0, R) \times \mathbb{R}^n} S \wedge d\chi_R \wedge J(d\chi_R) \wedge dx_I \wedge d\xi_I| \leq \epsilon^{-1} R^{-2} \int_{\mathbb{R}^n} S \wedge dd^\# |x| \wedge dd^\# \phi_I \leq \epsilon^{-1} R^{-2} D,$$

for some constant $D > 0$ independent of $R$. Thus the trace measure of the positive current $S \wedge d\chi_R \wedge J(d\chi_R)$ tends to 0 with $R$. Thus we find that the second term, $II$, tends to 0 as $R \to \infty$. In conclusion, we see that

$$\lim_{R \to \infty} \langle d\chi_R \wedge S, \pi^*(v \wedge w) \rangle = 0,$$

for every pair of forms $v$ and $w$ as above. Since every $(n - p - 1, n - p)$--form $\alpha$ can be written as a linear combination of forms of the type $v \wedge w$ as above, this implies that

$$\lim_{R \to \infty} \langle d\chi_R \wedge S, \pi^*(\alpha) \rangle = 0.$$

By definition, this mean precisely that $d(\pi_*(dd^\# f_1 \wedge \ldots \wedge dd^\# f_p)) = 0$, as desired. □

4. Tropical geometry

For a finite set $A$ in $\mathbb{Z}^n$ we let $P = \text{conv}(A)$, the convex hull in $\mathbb{R}^n$ of the set $A$.

**Definition 4.1.** A tropical polynomial is a function $f(x) = \max_{\alpha \in \mathcal{E}} (\nu(\alpha) + \alpha \cdot x)$, where $\nu : A \to \mathbb{R}$ is some arbitrary function. For a tropical polynomial $f$, we define the associated tropical hypersurface, which we will denote $V_f$, as the set where $f$ is not smooth.

Observe that a tropical polynomial is a convex function. Moreover, since the maximum of a finite number of affine functions is piecewise affine, we see that $V_f$ is the set where $f$ is not affine. This set coincides with the set where two or more of the elements which we take the maximum over obtain the maximum value at the same time. It is easy to realize that $V_f$ thus consist of finitely many affine hyperplanes (or rather convex polyhedras), glued together at $(n - 2)$--dimensional affine manifolds of $\mathbb{R}^n$. Now, let us extend the function $\nu$ to all of $\mathbb{R}^n$ by letting

$$\nu_\infty(x) = \begin{cases} \nu(x), & x \in A \\ \infty, & x \notin A \end{cases}.$$
The tropical polynomial $f$ then coincides with the Legendre transform of $\nu_{\infty}$. It is a well known fact of convex analysis that applying the Legendre transform twice to any function $g : \mathbb{R}^n \to \mathbb{R}$ will produce the largest convex function which is smaller than $g$ at any point. Thus, applying the Legendre transform to the tropical polynomial $f$ gives us the largest convex function on $\mathbb{R}^n$ which, when restricted to $A$, is less than or equal to $\nu$. We will denote this function by $\hat{\nu}$. It is not hard to realize that $\hat{\nu}$ is piecewise affine on $P$ and equal to $+\infty$ on $\mathbb{R}^n \setminus P$. Let us assume for the time being that the dimension $n = 2$. Then the set $\Gamma \subset P$ defined as the set where the function $\hat{\nu}$ is singular, is a graph which is dual to the tropical line $V_f$ in the following sense (cf. [12]): each edge of $\Gamma$ is perpendicular to an edge of $V_f$ and vice versa. One calls the graph $\Gamma$ a convex triangulation of the polytope $P$. Similar statements hold in higher dimensions as well.

We can associate weights, normal vectors and primitive integer vectors to the facets of $V_f$ in the following way: consider an $(n-1)$-dimensional facet $V$ of $V_f$. The set $V$ is the set where precisely two of the affine functions competing for the maximum in the tropical polynomial $f$, say $-\nu(\alpha_1) + \alpha_1 \cdot x$ and $-\nu(\alpha_2) + \alpha_2 \cdot x$, are equal and realize the maximum. The facet $V$ has two natural normal vectors defined from the data given, namely $\alpha_1 - \alpha_2$ and $\alpha_2 - \alpha_1$. We pick one of these two, and call it the normal vector $v$ associated to $V$. Note that a choice of normal vector $v$ induces an orientation on $V$ compatible with any fixed choice of orientation on $\mathbb{R}^n$. We will only be interested in the pair $(V, v)$ where we take the orientation of $V$ into account, and consequently it does not matter which vector we chose above to be the normal vector associated to $V$: If we instead had chosen $-v$, the orientation of $V$ would have been reversed. The weight $w$ is the absolute value of the greatest common divisor of the numbers $v^1, . . . , v^n$, where $v^j$ denotes the $j$:th component of the vector $v$. We let $N$ denote the primitive integer vector associated to $v = \alpha_1 - \alpha_2$, i.e., the vector in $\mathbb{Z}^n$ such that $wN = v$.

A tropical hypersurface $V_f$ thus consists of a finite number of convex polyhedras of dimension $(n - 1)$, call them $V_1, . . . , V_k$, which are glued together along convex polyhedras of dimension $(n - 2)$, which we denote by $W_1, . . . , W_r$. Now, assume that $W_1$ is the locus of intersection of $V_1, . . . , V_k$, and the sign of the corresponding normal vector $v_i$ has been chosen such that each $V_i$ induces the same orientation on $W_1$. We explain this last condition in detail. Fix an orientation of $W_1$ and let $\{e_1, . . . , e_{n-2}\}$ be a basis of $W_1$, compatible with the orientation chosen. Fix also one of the convex polyhedras adjacent to $W_1$, say $V_1$. Then there exists a unique unit normal of $W_1$ pointing into $V_1$, which we denote by $w_1$, and for which $\{w_1, e_1, . . . , e_{n-2}\}$ is a basis for $V_1$. We choose the sign of $v_1$ so that $\{v_1, w_1, e_1, . . . , e_{n-2}\}$ is a basis compatible with the fixed orientation of $\mathbb{R}^n$. Under these circumstances one can show:

**Proposition 4.2.** (Balancing property of tropical varieties, cf. [7]) With the above hypothesis the balancing condition holds around $W$:

\[
\sum_{i=1}^{k} v_i = 0.
\]

Let us study an example as to see how tropical polynomials may arise in practice.

Consider a complex algebraic hypersurface $\{h = 0\}$ in $\mathbb{C}^n$, where $h$ is a Laurent polynomial $h = \sum_{\alpha \in A} c_\alpha z^\alpha$, where multi-index notation is used. Let $P = \text{conv}(A)$ be the Newton polytope associated with $f$. We consider the function $\text{Log} : \mathbb{C}^n \to \mathbb{R}^n$, given by $\text{Log}(z_1, . . . , z_n) = (\log |z_1|, . . . , \log |z_n|)$, and define $A_h = \text{Log}(\{h = 0\})$. This
set $A_t \subset \mathbb{R}^n$ is called the amoeba of the polynomial $h$. Tropical pictures arise when we start deforming the amoeba, and shrink its width to 0. To make this precise, we let for $t > 0$, $\log_t(x) = \log(x)/\log(t)$, and define $\log_t$ by exchanging log for $\log_t$ in the definition of $Log$. Also we define $A^t_h = \log_t(\{h = 0\})$. Then as $t \to 0$, the sets $A^t_h$ converges to a set in the Hausdorff topology (cf. [4]), which we denote by $\mathcal{S}_h$. This set $\mathcal{S}_h$ can actually be seen to be piecewise affine, and all its pieces have rational slope. Thus, it constitutes a tropical variety.

**Example 4.3.** Let us consider the two dimensional case. We choose the polynomial $h$ to be $1 + z^2 + w$ where $(z, w)$ are coordinates for $\mathbb{C}^2$. Its Newton polytope is then the triangle with vertices at the points $(0,0), (2,0)$, and $(0,1)$. When considering the image of $A_t \subset \mathbb{R}^2$, where we denote the coordinates on $\mathbb{R}^2$ with $(x,y)$, under the map $Log$, points at which one of the coordinates is 0 will be sent to $-\infty$, so we start searching for those. If $w = 0$ then $z = \pm 1$, if we are to have $(z, w) \in \{h = 0\}$. This point will be sent under the $Log$-map to the ray along the $y$-axis starting at $(0,0)$ and ending in $(0,-\infty)$. Similarly, if $z = 0$ then $w = -1$, so this point will be sent to the ray along the $x$-axis, starting at $(0,0)$ ending in $(-\infty, 0)$. Also, for $z$ and $w$ large, and $(z, w) \in \{h = 0\}$, we have that $\log |w| = 2 \log |z|$, that is $y \approx 2x$. Thus the amoeba will have three asymptotic lines, namely the sets $(-\infty,0) \times \{0\}$, $\{0\} \times (-\infty,0)$ and $\{y = 2x\}$. Moreover, one can show that each component of the amoeba is convex (cf. [9]). It is not hard to realize that if we consider the limit of $A^t_h$ as $t$ gets closer and closer to 0, the picture is that the “deformed” amoeba converges to exactly the asymptotic lines we have found, and we obtain the tropical curve given by the tropical polynomial $\max\{0, y, 2x\}$. At this point we should also note that each of the directional vectors for the lines are in fact normal vectors to the Newton polytope. As in the above discussion, we say the the $\mathcal{S}_h$ is dual to the polytope $P$.

Tropical geometry can also be seen as algebraic geometry over a non-archimedean field, $K$. The attribute non-archimedean means that the field has a norm which satisfy a stronger condition than the triangle inequality, namely that

$$|x + y| \leq \max\{|x|, |y|\}.$$ 

Here we let $K$ be the field of Puiseux series, namely the set of all formal power series $\sum_{q \in \mathbb{Q}} a_q t^q$, where we demand that the set of all $q$ such that $a_q \neq 0$ is bounded from below. We can equip $K$ with a valuation map $\nu : K \to \mathbb{R}$, by demanding that $\nu\left(\sum_{q \in \mathbb{Q}} a_q t^q\right)$ is the infimum of all $q$ such that $a_q \neq 0$. For instance $\nu(3t^{-22} + 2t^2 + t^4 + 4) = -22$. Let us now consider the polynomial ring $K[z_1, ..., z_n]$, and an element in it, $G$. Thus $G = \sum_{\alpha_i \in A} r_{\alpha_i} z^{\alpha_i}$, for $A$ some finite subset of $\mathbb{Z}^n$, and $r_{\alpha_i} \in K$. To this $G$ we associate its tropicalization

$$\text{trop}(G)(x) = \max_{\alpha_i \in A} \{\alpha_i \cdot x - \nu(r_{\alpha_i})\},$$

where $x \in \mathbb{R}^n$, and $\alpha \cdot x$ is the scalar product between $x$ and $\alpha$. For instance, $\text{trop}(t^{-2}zw + tw^2)(x,y) = \max\{-2 + x + y, 1 + 2y\}$. Similar as for the function $Log$ defined above, we put $\text{Val}(z_1, ..., z_n) = (\text{val}(z_1), ..., \text{val}(z_n))$. We now come to an important point: One can show ([4]) that the closure of the set $\text{Val}(\{G = 0\})$ is equal to the set in $\mathbb{R}^n$ where the maximum $\text{trop}(G)(x) = \max_{\alpha_i \in A} \{\alpha_i \cdot x - \nu(r_{\alpha_i})\}$ is obtained by two or more of the $\alpha_i$. Thus the closure of the set $\text{Val}(\{G = 0\})$ defines a tropical variety. Of course, by letting the function $\nu$ in definition [4] be
equal to \( \alpha_i \mapsto \nu(r_{\alpha_i}) \), the tropical polynomial will be just \( \text{trop}(G) \), and so we could equally well take the following as a definition of a tropical variety:

**Proposition 4.4.** (\( \mathbb{R} \)) A tropical variety is given by the closure of \( \text{Val}([G = 0]) \) in \( \mathbb{R}^n \), where \( G \in \mathbb{K}[z_1, \ldots, z_n] \).

**Remark 4.5.** Let \( h = \sum_{a \in A} c_\alpha z^\alpha \) be a complex polynomial with \( h(0) = 0 \), where \( A \) is a finite subset of \( \mathbb{Z}^n \). In the complex setting, there is a generalization of the Lelong number, called Kiselman’s directed Lelong number, denoted \( \gamma_{z, \varphi}(x) \), which gives more precise information concerning the singularities of \( \varphi \). It depends on three parameters: a plurisubharmonic function \( \varphi \) on \( \mathbb{C}^n \), a point \( z \in \mathbb{C}^n \), and a vector in \( x \in \mathbb{R}_+^n \), and if \( x = (1, \ldots, 1) \) it reduces to the ordinary (complex) Lelong number. It is well known that \( x \mapsto \gamma_{z, \varphi}(x) \) is a convex function, for \( x \in \mathbb{R}_+^n \). For our discussion, it suffices to say that, with \( \varphi(z) = \log(h(z)) \),

\[
\gamma_{0, \varphi}(x) = \max_{\alpha \in A} \{ \alpha \cdot x \}.
\]

This corresponds to choosing \( K = \mathbb{C} \) and endowing \( \mathbb{K} \) with the trivial valuation \( \nu(w) = 0 \) for every \( w \in \mathbb{C} \). Indeed, we then have

\[
\text{trop}(h)(x) = \max_{\alpha \in A} \{ \alpha \cdot x \} = \gamma_{0, \log(h(z))}(x).
\]

For \( \nu \) a valuation on \( \mathbb{K} \), we put

\[
\text{trop}_\nu(\log(h))(x) = \max_{\alpha \in A} \{ \alpha_i x - \nu(r_{\alpha_i}) \}.
\]

Thus, if we restrict ourselves to complex polynomials, \( \text{trop}_\nu \) could be considered as a generalization of Kiselman’s Lelong number. It would be interesting to know if one could extend \( \text{trop}_\nu \) to act on arbitrary plurisubharmonic functions.

### 4.1. Tropical geometry and super forms.
Since a tropical polynomial \( f \) is the maximum of a finite number of \( \mathbb{Z} \)-affine functions on \( V \) and since \( dd^\# f = 0 \) at points where \( f \) is affine, we must have that \( \text{Supp}(dd^\# f) = V_f \). Thus the support of the current \( dd^\# f \) coincides as a point set with the tropical hypersurface \( V_f \). We make the following definition.

**Definition 4.6.** The support of a current \( T \) is of dimension \((n - 1)\) if \( \text{Supp}(T) \) is a piecewise smooth manifold of dimension \((n - 1)\), that is, \( \text{Supp}(T) \) consists of a finite number of smooth manifolds of dimension \( n - 1 \), glued together along manifolds of lower dimension.

We can now prove the fundamental result of this paper.

**Proposition 4.7.** There is a one to one correspondence between tropical hypersurfaces \( V_f \), and closed, positive \((1,1)\)-currents \( T \) whose support is of dimension \( n - 1 \), and whose normal vectors (see below) are integral.

**Proof.** Let \( T \) be as in the hypothesis, and denote by \( A \) the support of \( T \). We first show that \( A \) is a piecewise affine manifold. Fix a point \( x \in A \), and a small ball \( B \) centered at \( x \), such that \( B \setminus A \) consists of precisely two components; call them \( C_1 \) and \( C_2 \). By Proposition 1.14 both \( C_1 \) and \( C_2 \) are convex, which implies that each \((n - 1)\)-dimensional piece of \( A \) must be affine. Thus \( A \) is piecewise affine. Now, by Proposition 1.13, we can find a convex function \( f \) such that \( T = dd^\# f \).
Let us denote by $V_1, ..., V_N$ the $(n - 1)$-dimensional (affine) pieces of $A$. For each $i = 1, ..., N$, there is a vector $v_i \in \mathbb{V}$ and a real number $c_i$ such that, for $x \in V_i$,

$$f(x) = -c_i + v_i \cdot x.$$ 

The convexity of $f$ implies that, in fact,

$$f(x) = \max_{i=1,...,N} (-c_i + v_i \cdot x),$$

for $x \in \mathbb{V}$. The condition that the currents normal vectors are integral, means that each vector $v_i$ belongs to $\mathbb{Z}^n$ (under the identification of $\mathbb{V}$ with $\mathbb{R}^n$). If this is the case, then $f$ is actually a tropical polynomial, and thus we can conclude that $\text{Supp}(T)$ coincides with a tropical hypersurface. This establishes one part of the correspondence. The second part is easier: for each tropical hypersurface $V_f$ we let $T = dd^\# f$; then $T$ satisfies the hypothesis of the proposition.

The arguments used above immediately give:

**Corollary 4.8.** If the support $\text{Supp}(T)$ is of dimension $n - 1$, for a closed, positive $(1, 1)$-current $T$, then $\text{Supp}(T)$ is piecewise affine.

By the previous discussion, we know that $\text{Supp}(T) = V_f$ consists of a finite number of convex polyhedras $V_i$, whose affine hull is of dimension $n - 1$, glued together at affine convex polyhedras $W_k$ of dimension $n - 2$. Let us recall the discussion before Proposition 4.2: each facet $V_i$ is the set where, for some $\alpha_1, \alpha_2 \in A$,

$$-c_{\alpha_1} + v_{\alpha_1} \cdot x = -c_{\alpha_2} + v_{\alpha_2} \cdot x$$

attains the maximum defining the tropical polynomial $f$, and we defined the normal vector of $V_i$ to be, up to sign, equal to $v_i = \alpha_1 - \alpha_2$. Thus $v_i$ is a normal vector to $V_i$ whose length is determined by the tropical polynomial. We make the following definition:

**Definition 4.9.** The normal 1-form associated to $V_i$ is defined as $v^*_i = d(v_i \cdot x)$.

Let $V$ be a hyperplane in $\mathbb{R}^n$ with normal $v$, and let $\delta_V$ denote the surface measure of $V$. We will consider the $(1, 1)$-current

$$\frac{1}{|v|} \delta_V v^* \wedge J(v^*),$$

whose action on an $(n - 1, n - 1)$-form $\alpha$ is defined by

$$\left< \frac{1}{|v|} \delta_V v^* \wedge J(v^*), \alpha \right> = \frac{1}{|v|} \int_V \frac{v^* \wedge J(v^*) \wedge \alpha}{\omega_n} \delta_V.$$

Observe that this current does not depend on which sign we have chosen for the normal vector $v$. This current represent a tropical variety:

**Proposition 4.10.** Let $V \subset \mathbb{R}^n$ be a hyperplane, determined by a normal vector $v = (v_1, ..., v_n)$, and define $f = \max (0, v \cdot x)$. Then

$$dd^\# f = \frac{1}{|v|} \delta_V v^* \wedge J(v^*).$$

Moreover, we have the following equality

$$[V] \wedge J(v^*) = \frac{1}{|v|} \delta_V v^* \wedge J(v^*),$$

where $[V]$ is the current of integration on $V$, with orientation determined by $v$. 

(4.1)
Proof: We prove equation (4.1) first. We have the following equality of currents on \( \mathbb{R}^n \):

\[
\frac{1}{|v|} \delta_V v^* = [V],
\]

where \([V]\) is the current of integration of \(V\), defined in a natural way as

\[
\langle [V], \alpha \rangle = \int_V \alpha,
\]

for \(\alpha\) a compactly supported \(\text{dim} V\)-form on \(\mathbb{R}^n\). To prove this we extend \(\{v\}\) to an orthonormal basis of \(\mathbb{R}^n\), compatible with the orientation chosen, which we denote \(\{|v|^{-1}v, e_1, \ldots, e_{n-1}\}\). For simplicity, we use the notation \(e^* = e_1^* \wedge \ldots \wedge e_{n-1}^*\). Then we need only to prove the formula for forms of the type \(\alpha_0 e^*\), where \(\alpha_0\) is a function.

But, since \(\delta_V = e^*\), and \(v^* \wedge e^* = |v|dx_1 \wedge \ldots \wedge dx_n\), we see that

\[
\left\langle \frac{\delta_V}{|v|} v^*, \alpha_0 e^* \right\rangle = \left\langle \delta_V, \alpha_0 |v|^{-1} v^* \wedge e^* \right\rangle = \int_V \alpha_0 e^*.
\]

On the other hand,

\[
\langle [V], \alpha_0 e^* \rangle = \int_V \alpha_0 e^*,
\]

which proves the formula (4.2). Thus, we see that

\[
\frac{1}{|v|} \delta_V v^* \wedge J(v^*) = [V] \wedge J(v^*).
\]

We now proceed to prove the first formula of the proposition. Recall that if \(P' \subset V\) is a submanifold of the same dimension as that of \(V\), and with piecewise smooth boundary, then the current \(T := [P'] \wedge J(v^*)\) satisfies

\[
\langle dT, \alpha \rangle = \langle [\partial P'] \wedge J(v^*), \alpha \rangle,
\]

which follows from Stokes’ theorem.

We begin by considering the function \(f = \max \{0, x_n\}\). To compute \(dd^\# f\) we choose for \(\epsilon > 0\), a family of smooth, one-variable functions \(g_\epsilon\) satisfying

\[
\lim_{\epsilon \to 0} g_\epsilon(t) = \max \{0, t\}, \text{ and } \lim_{\epsilon \to 0} g''_\epsilon = \delta_0 \text{ (the Dirac measure at } 0)\).

For such a family \(g_\epsilon\), we put

\[
f_\epsilon(x_1, \ldots, x_n) = g_\epsilon(x_n).
\]

Then, for each \(\alpha \in \mathcal{E}^{n-1, n-1}\),

\[
\langle dd^\# f_\epsilon, \alpha \rangle = \left\langle f''_\epsilon dx_n \wedge d\xi_n, \alpha \right\rangle = \left\langle f''_\epsilon dx_n \wedge d\xi_n, \alpha_{nn} dx_n \wedge d\xi_n \right\rangle
\]

\[
= \int_{\mathbb{R}^n} f''_\epsilon \alpha_{nn} dx_1 \wedge \ldots \wedge dx_n,
\]

where \(\alpha_{nn}\) is the coefficient in front of \(dx_n \wedge d\xi_n\) in the sum defining \(\alpha\). Thus we see that

\[
\lim_{\epsilon \to 0} \langle dd^\# f_\epsilon, \alpha \rangle = \int_{\mathbb{R}^{n-1}} \alpha_{nn}(x_1, \ldots, x_{n-1}, 0) dx_1 \wedge \ldots \wedge dx_{n-1},
\]

which is the same as saying

\[
dd^\# f = dd^\# \max \{0, x_n\} = [\{x_n = 0\}] \wedge d\xi_n.
\]

Now, let’s turn to the general case: as above, let \(\{v/|v|, e_1, \ldots, e_{n-1}\}\) be an orthonormal basis, and let \(F\) correspond to the matrix \((v/|v|, e_1, \ldots, e_{n-1})\) in the standard basis of \(\mathbb{R}^n\). We again use the notation \(e^* = e_1^* \wedge \ldots \wedge e_{n-1}^*\). Then, if we consider
the action of $dd^f$ on the form $\alpha e^* \wedge J(e^*)$, since $\det F = 1$ we get by (3.4) and the discussion above, that
\[
\langle dd^f \max(0, v \cdot x), \alpha e^* \wedge J(e^*) \rangle = \\
\langle dd^f \max(0, |v|x_n), F^*(\alpha e^* \wedge J(e^*)) \rangle = \\
|v| \int_{\{x_n = 0\}} F^*(\alpha e^*) = |v| \int_{\{v \cdot x = 0\}} \alpha e^*.
\]
On the other hand,
\[
\langle \{v \cdot x = 0\} \wedge J(v^*), \alpha e^* \wedge J(e^*) \rangle = |v| \int_{\{v \cdot x = 0\}} \alpha e^*,
\]
where we used that $\int_Y J(v^*) \wedge J(e^*) = |v|$. Since we need only to consider forms that are multiples of $e^* \wedge J(e^*)$, we have proved that
\[
\{v \cdot x = 0\} \wedge J(v^*) = dd^f \max(0, v \cdot x),
\]
which is what we aimed for.

For a tropical hypersurface $V_f$ consisting of $(n - 1)$-dimensional convex polyhedras $V_i$ as discussed before, we consider the current defined as $T' = \sum_{i=1}^N [V_i \wedge J(v_i^*)]$, and let $T = dd^f f$. The previous proposition shows that $\text{Supp}(T - T')$ is of dimension at most $n - 2$. Moreover, $T - T'$ is closed. These hypotheses actually implies that $T - T' = 0$ as follows from the following lemma.

Lemma 4.11. Let $S$ be a closed $(p, q)$–current whose coefficients are measures and whose support is a piecewise affine manifold $M \subset \mathbb{R}^n$ of co-dimension $p + 1$. Then $S = 0$.

Proof. Let $x \in M$. Assume that, for a small neighbourhood $U$ of $x$, we can choose coordinates so that $M \cap U = \{x_1 = x_2 = \ldots = x_{p+1} = 0\}$. Since $S$ has measure coefficients, it is easy to see that
\[
x_1 S = x_2 S = \ldots = x_p S = 0
\]
on $U$. It follows that $d(x_1 S) = dx_1 \wedge S = 0$, thanks to $S$ being closed. Thus, we can write $S = S' \wedge dx_1$ for a $d$–closed $(p - 1, q)$–current $S'$. By the same means $x_2 S' = 0$ from which we see that $dx_2 \wedge S' = 0$ and so $S' = S'' \wedge dx_2$ for some $(p - 2, q)$–current $S''$. Repeating the argument, we eventually find that there is a $(0, q)$–current $S'''$ such that $S = S''' \wedge dx_1 \wedge \ldots \wedge dx_p$. As before, this $S'''$ satisfies the equation $S''' x_{p+1} = 0$, which implies $S''' \wedge dx_{p+1} + dS''' x_{p+1} = 0$. Thus $S''' \wedge dx_{p+1} = 0$ on $M$, and since $S''' = \sum_{|j| = q} S_j d\xi_j$ for some measures $S_j$, we see that $S'''$, and hence $S$, vanish on $U$. Thus we have shown that $S$ carries no mass on the pieces of $\text{Supp}(S)$ which are of pure co-dimension $p + 1$. Thus $S$ has support that is a piecewise affine manifold of co-dimension $p + 2$. Iterating the procedure above gives the desired result. \hfill \Box

Concluding the discussion before the lemma, we obtain the following result:

Proposition 4.12. With the notation above, $dd^f f = \sum [V_i] \wedge J(v_i^*)$.

We can also show the following proposition, shedding more light on the connection between currents and tropical hypersurfaces.
Proposition 4.13. Let $T = \sum [V_i] \wedge J(v_i^*)$ be a tropical hypersurface. Then the condition $dT = 0$ is equivalent to the balancing condition (cf. Proposition 4.12): for each $(n-2)$-dimensional affine manifold $W$ defined as the locus where $m$ hyperplanes $V_1, \ldots, V_m$ meet, we have that $\sum_{i=1}^m v_i = 0$.

Proof. For $1 \leq j \leq n$, we let $v_i^j$ denote the $j$th component of the vector $v_i$. Each $V_i$ has a boundary built up from a number of $(n-2)$ dimensional pieces which we call $P_i^r$. For a fixed $W$ where $V_1, \ldots, V_m$ meet, we then have finitely many $P_i^r$, say $P_1^1, \ldots, P_k^1$ coinciding with $W$ as sets. Fix a $(n-2, n-1)$-form $\alpha = \sum_{I,j} \alpha_{I,j} dx_I \wedge d\xi_j$ with compact support in a small neighbourhood of a point on $W$. We can choose the support so small that $W$ is the only part of co-dimension two of $V_j$ that lies in $\text{Supp}(\alpha)$. Then, by Stokes’ theorem,

$$\langle dT, \alpha \rangle = \left( \sum_{i=1}^m [\partial V_i] \wedge J(v_i^*), \alpha \right) = \left( \sum_{i=1}^m [P_i^1] \wedge J(v_i^*), \alpha \right).$$

Thus, since $J(v_i^*) \wedge d\xi_j = v_i^j \delta_{\xi_1} \wedge \ldots \wedge d\xi_n$,

$$\langle dT, \alpha \rangle = \sum_{i=1}^m \left[ P_i^1 \right] \wedge J(v_i^*) \sum_{I,j} \alpha_{I,j} dx_I \wedge d\xi_j = \pm \sum_{j,I} \left( \sum_{i=1}^n v_i^j \right) \int_W \alpha_{I,j} dx_I.$$

Thus, if $\sum_{i=1}^m v_i = 0$, this last sum is 0, whence $\langle dT, \alpha \rangle = 0$. Since we can do this for every $W$, we see that $\dim(\text{Supp}(dT)) \leq n - 3$ and since $dT$ has measure coefficients, Lemma (4.11) implies that $dT = 0$. Conversely, if $\langle dT, \alpha \rangle = 0$, then

$$\sum_{j,I} \left( \sum_{i=1}^n v_i^j \right) \int_W \alpha_{I,j} dx_I = 0$$

and so, to see that the balancing property holds, it suffices to choose, for every fixed $I_0, J_0$, a form $\alpha$ such that $\int_W \alpha_{I_0,j_0} dx_{i_0} = 1$ and $\int_W \alpha_{I,j} = 0$ for $I \neq I_0, J \neq J_0$. □

Example 4.14. For the tropical hyperplane corresponding to the polynomial $f = \max \{0, v \cdot x\}$ we have

$$\nu_0(V_f) = \nu_0(\text{dd}^\# f) = |v|.$$

To see this, let $V$ be the singularity locus of $f$. Then, since $T := \text{dd}^\# f = [V] \wedge J(v^*)$, we have

$$\Theta_T(B(0,r)) = \frac{1}{2^{n-1} (n-1)!} \sum_{i=1}^n v_i \int_{(B(0,r) \cap V) \times \mathbb{R}^n} d\xi_i \wedge (\text{dd}^\# |x|^2)^{n-1}$$

and it easy to see that,

$$\frac{1}{2^{n-1} (n-1)!} \int_{(B(0,r) \cap V) \times \mathbb{R}^n} d\xi_i \wedge (\text{dd}^\# |x|^2)^{n-1} = \frac{n}{|v|} \text{Vol}(B^{n-1}) r^{n-1}.$$

Thus

$$\Theta_T(B(0,r)) = \text{Vol}(B^{n-1}) |v| r^{n-1},$$

and so

$$\nu_x(\text{dd}^\# f) = \lim_{r \to 0} \frac{\Theta_T(B(x,r))}{r^{n-1}} = |v|,$$

as claimed.

An easy adaptation of this example shows the following:
Proposition 4.15. Let $T = \sum |V_i| J(v_i^*)$ and let $x$ be a point where a finite number of the polyhedra $V_i$ meet at a convex polyhedron of co-dimension 2. Assume, after reordering, that they are $V_1, ..., V_m$. Then

$$\nu_s(T) = \frac{1}{2} \sum_{i=1}^m |v_i|.$$ 

4.2. Intersection theory and tropical varieties of higher co-dimension.

Let $f_1, ..., f_p$ be tropical polynomials with corresponding tropical hypersurfaces $V_{f_1}, ..., V_{f_p}$.

Definition 4.16. The intersection of $V_{f_1}, ..., V_{f_p}$ is defined as the strongly positive $(p, p)$-current

$$V_{f_1} \wedge ... \wedge V_{f_p} := dd^\# f_1 \wedge ... \wedge dd^\# f_p.$$ 

By Proposition 2.7 the intersection is stable in the following sense: if $V_\epsilon \to V$, then

$$V_\epsilon \wedge V_1 \wedge ... \wedge V_p \to V \wedge V_1 \wedge ... \wedge V_p,$$ 

as $\epsilon \to 0$. However, it is important to realize that this does not imply that the support of $V_\epsilon \wedge V_1 \wedge ... \wedge V_p$ tends to the support of $V \wedge V_1 \wedge ... \wedge V_p$ in the Hausdorff topology (see Example 4.21). We proceed by investigating properties of intersections of tropical hypersurfaces.

Proposition 4.17. Let $v_i$ be linearly independent vectors in $\mathbb{R}^n$, for $1 \leq i \leq n$, and define $f_i(x) = \max\{0, v_i \cdot x\}$, where $x \in \mathbb{R}^n$. Then

$$dd^\# f_1 \wedge ... \wedge dd^\# f_n = c \delta_0$$ 

where

$$c = |\text{det}(v_1, ..., v_n)|.$$ 

Proof. Let $F$ be the linear map corresponding to the inverse of the matrix $(v_1, ..., v_n)$, so that $|\text{det}|F|| = c^{-1}$. Then, $f_1 \circ F = \max(0, x_i)$, and consequently

$$F^* dd^\# f_i = dd^\# \max\{0, x_i\}.$$ 

Using formula (3.4) we see that for a compactly supported, smooth function $g$,

$$\langle dd^\# f_1 \wedge ... \wedge dd^\# f_n, g \rangle = c \langle F^* (dd^\# f_1 \wedge ... \wedge dd^\# f_n), F^* g \rangle = c \langle dd^\# \max\{0, x_1\} \wedge ... \wedge dd^\# \max\{0, x_n\}, g \circ F \rangle.$$ 

By Fubini’s theorem and equation (4.3), the last line of the above equation is equal to $c \cdot (g \circ F)(0) = c \cdot g(0)$, which finishes the proof.

If $V_i$ is a tropical hyperplane of the form

$$V_i = dd^\# f_i = \{(v_i \cdot x = 0)\} \wedge J(v_i^*)$$ 

for each $1 \leq i \leq q$, the same argument as in the above proof gives us that

$$V_1 \wedge ... \wedge V_q = dd^\# f_1 \wedge ... \wedge dd^\# f_q = \{(v_1 \cdot x = 0) \cap ... \cap (v_q \cdot x = 0)\} \wedge J(v_1^*) \wedge ... \wedge J(v_q^*).$$ 

Notice that if two of the $q$ hyperplanes are parallel, then the intersection vanishes. Thus, in this case the support, $\text{Supp}(V_1 \cdot ... \cdot V_q)$, is either of dimension $n-q$ or empty. This property holds for general tropical hypersurfaces as well:
Proposition 4.18. Let $V_{f_1},...,V_{f_p}$ be tropical hypersurfaces such that $V_{f_1} \wedge ... \wedge V_{f_p} \neq 0$. Then,

$$\dim(\text{Supp}(V_{f_1} \wedge ... \wedge V_{f_p})) = n - p.$$  

Proof. By Proposition 4.12, each tropical hypersurface $V_i$ can be written as

$$V_i = \sum_{i=1}^k [V_i] \wedge J(v_i^*),$$

where each $V_i$ is a convex polyhedron of dimension $n - 1$. Each $[V_i]$ can be considered as $\chi_i[V_i]$ where $\tilde{V}_i$ denotes the affine hull of $V_i$, and $\chi_i$ is the characteristic function

$$\chi_i(x) = \begin{cases} 1, & x \in V_i \\ 0, & x \notin V_i \end{cases}.$$  

Define the $(1,1)$–current $\tilde{V}$ by

$$\tilde{V} = \sum_{i=1}^k [\tilde{V}_i] \wedge J(v_i^*).$$

This current is positive and closed since each summand is, and satisfies the relation $\text{Supp}(V) \subset \text{Supp}(\tilde{V})$.

Thus the inclusion $\text{Supp}(V_{f_1} \wedge ... \wedge V_{f_p}) \subset \text{Supp}(\tilde{V}_{f_1} \wedge ... \wedge \tilde{V}_{f_p})$ holds, which implies, since $\dim(\text{Supp}(\tilde{V}_{f_1} \wedge ... \wedge \tilde{V}_{f_p})) = n - p$, that $\dim(\text{Supp}(V_{f_1} \wedge ... \wedge V_{f_p})) \leq n - p$.

By the assumption that $V_{f_1} \wedge ... \wedge V_{f_p} \neq 0$ we see that in fact equality must hold, since $\dim(\text{Supp}(V_{f_1} \wedge ... \wedge V_{f_p})) < n - p$ would force $V_{f_1} \wedge ... \wedge V_{f_p} = 0$ by Corollary 3.5. 

The following result generalizes the case of positive $(1,1)$–currents:

Proposition 4.19. Let $T$ be a strongly positive $(p,p)$-current such that $\text{Supp}(T)$ is a piecewise smooth manifold of dimension $n - p$. Then $\text{Supp}(T)$ is piecewise affine.

Proof. Let $L$ be an affine subspace of $\mathbb{R}^n$ of dimension $n - p + 1$ such that if, $\pi_L$ denotes the projection onto $L$, $\pi_L$ is proper on $\text{Supp}(T)$. By Proposition 4.18 this holds for almost every subspace $L$. By Proposition 3.1 we see that if the push-forward is non-zero, its dimension is $n - p$. Thus, for a generic subspace $L$ as above, $(\pi_L)_*T$ is of co-dimension 1 in $L$, so by Corollary 4.8, we see that $\text{Supp}((\pi_L)_*T)$ is piecewise affine for almost any $\pi_L$. Since $\text{Supp}((\pi_L)_*T) \subset \pi_L(\text{Supp}(T))$, we conclude that $\text{Supp}T$ is piecewise affine. 

As an immediate corollary, we obtain:

Corollary 4.20. With the notation of Proposition 4.18, $\text{Supp}(V_{f_1} \wedge ... \wedge V_{f_p})$ is piecewise affine.
Example 4.21. For a simple example, assume that we are in $\mathbb{R}^2$ and consider the intersection $dd^# f \wedge dd^# g$ where $f = \max(0, v_1 x + v_2 y)$, and $g = \max(0, w_1 x + w_2 y)$ where $(v_1, v_2) \neq (w_1, w_2)$ are vectors in $\mathbb{R}^2$. This corresponds to the intersection between the lines $\{v_1 x + v_2 y\}$ and $\{w_1 x + w_2 y = 0\}$. Indeed, by Proposition 4.17, $dd^# f \wedge dd^# g = |\det \begin{bmatrix} w_1 & v_1 \\ w_2 & v_2 \end{bmatrix}| \delta_0$.

Thus the intersection of the two lines is the origin with intersection multiplicity determined by the volume of the parallelepiped spanned by the defining vectors of the two lines. As was noticed above, we see that if the two lines coincide, the intersection vanishes.

Let us take $(v_1, v_2) = (w_1, w_2) = (1, 0)$ with associated tropical lines $V$ and $W$ and let us perturb $W$ slightly by considering the tropical line $W_\epsilon$ associated to $g_\epsilon(x) = \max\{(1 + \epsilon)x_1 + \epsilon x_2, 0\}$. Then

$$W_\epsilon \cdot V = \delta_0 |\det \begin{bmatrix} 1 & 1 + \epsilon \\ 0 & \epsilon \end{bmatrix}| = \delta_0 \cdot \epsilon,$$

and

$$W_\epsilon \cdot V \to W \cdot V,$$

as $\epsilon \to 0$. But, $\text{Supp}(W \cdot V) = \emptyset$ and $\text{Supp}(W_\epsilon \cdot V) = \{0\}$, which shows that the condition $W_\epsilon \cdot V \to W \cdot V$ does not imply that $\text{Supp}(W_\epsilon \cdot V) \to \text{Supp}(W \cdot V)$.

These results motivate the following definition:

Definition 4.22. A tropical variety of co-dimension $k$ is the support of a strongly positive $(k,k)$-current whose support have co-dimension $k$, where we demand that each of the affine pieces should have rational slope.

A piece have rational slope if its affine hull, which is a plane of co-dimension $k$, is the set where $k$ linear forms with integer coefficients vanish.

Proposition 4.23. Let $V_1, \ldots, V_k$ be tropical hypersurfaces. Then $V_1 \wedge \ldots \wedge V_k$ is a tropical variety of co-dimension $k$.

Proof. We know that $V_1 \wedge \ldots \wedge V_k$ is a closed, strongly positive $(k,k)$—current. Moreover, by Proposition 4.18 the dimension of its support is bounded from above by $n - k$, and since

$$\text{Supp}(V_1 \wedge \ldots \wedge V_k) \subset \text{Supp}(V_1) \cap \ldots \cap \text{Supp}(V_k),$$

by equation (2.4), each piece has rational slope. Thus it is a tropical variety of co-dimension $k$. $\square$

The set theoretic intersection of two tropical hypersurfaces need not coincide with the support of a tropical variety. Indeed, if $f = \max\{0, x, y\}$ and $g = \max\{0, x - y\}$ then the set theoretic intersection of $V_f$ and $V_g$ is the half-ray $\{(x, y) : y = x, x \geq 0\}$ which is not a tropical variety (for instance, it does not satisfy the balancing property). However, $V_f \cap V_g$ is equal to $\delta_0 \omega_n$, which is a tropical variety.

Remark 4.24. The intersection theory developed here seems to fit well with the intersection theory for tropical geometry considered in [8].
4.3. **Bezout’s theorem.** We use the ideas we have developed to prove known theorems within tropical geometry. Recall that we associated to an element \( f \in \mathcal{L} \) the function
\[
\hat{f}(x) = \lim_{t \to \infty} \frac{f(tx)}{t},
\]
and that by Proposition 2.20 we have the following relation between \( f \) and \( \hat{f} \):
\[
\int_{\mathbb{R}^n \times \mathbb{R}^n} (dd^\# f)^n = \int_{\mathbb{R}^n \times \mathbb{R}^n} (dd^\# \hat{f})^n.
\]
Let us explore the effects of this result to tropical polynomials. For \( f(x) = \max_{\alpha \in A} \{c_\alpha + \alpha \cdot x\} \) it is easy to see that \( \hat{f}(x) = \max_{\alpha \in A} \{\alpha \cdot x\} \). Relating to the discussion in the beginning of section 4, this means that if \( f \) corresponds to a convex triangulation of \( \text{conv}(A) \) then \( \hat{f} \) corresponds to “forgetting” this triangulation. In fact, since
\[
\max_{\alpha \in A} \{\alpha \cdot x\} = \max_{\alpha \in \text{conv}(A)} \{\alpha \cdot x\},
\]
we see that \( \hat{f} \) is just the support function of the set \( \text{conv}(A) \).

**Proposition 4.25.** Let \( f_1, \ldots, f_n \) be tropical polynomials defined by
\[
 f_i = \max_{\alpha \in A_i} \{c_\alpha^i + \alpha \cdot x\},
\]
where each \( A_i \) is a finite set of point of \( \mathbb{Z}^n \), and \( c_\alpha^i \) are real numbers. Let \( \tilde{A}_i = \text{conv}(A_i) \). Then \( \tilde{f}_i \) is the support function of \( \tilde{A}_i \) and
\[
\int_{\mathbb{R}^n \times \mathbb{R}^n} dd^\# f_1 \wedge \ldots \wedge dd^\# f_n = n! \cdot V(\tilde{A}_1, \ldots, \tilde{A}_n).
\]

**Proof.** It is clear that, if \( g = f_1 + \ldots + f_n \), then \( \hat{g} = \hat{f}_1 + \ldots + \hat{f}_n \). Thus, (4.5) implies that, for every \((t_1, \ldots, t_n) \in \mathbb{R}^n\),
\[
\int_{\mathbb{R}^n \times \mathbb{R}^n} (dd^\# (\sum_{j \in J} t_j f_j))^n = \int_{\mathbb{R}^n \times \mathbb{R}^n} (dd^\# (\sum_{j \in J} t_j \hat{f}_j))^n
\]
and so, by comparing coefficients, we see that
\[
\int_{\mathbb{R}^n \times \mathbb{R}^n} dd^\# f_1 \wedge \ldots \wedge dd^\# f_n = \int_{\mathbb{R}^n \times \mathbb{R}^n} dd^\# \hat{f}_1 \wedge \ldots \wedge dd^\# \hat{f}_n.
\]
Since \( \hat{f}_i \) is the support function of the set \( \tilde{A}_i \), we obtain from Proposition 2.18 that
\[
\int_{\mathbb{R}^n \times \mathbb{R}^n} dd^\# f_1 \wedge \ldots \wedge dd^\# f_n = n! \cdot V(\tilde{A}_1, \ldots, \tilde{A}_n).
\]

**Remark 4.26.** In the complex setting, there is an analogue of the associated function \( f \), called the local indicator associated to a plurisubharmonic function. See for instance the article [10].

Let us apply the above Proposition to obtain, in an easy way, two results from tropical geometry. We stress that these are not new results. Let us assume for the moment that \( n = 2 \). A tropical curve associated to a tropical polynomial \( f = \max_{\alpha \in A} \{c_\alpha + \alpha \cdot x\} \) is of degree \( d \) if \( \text{Newt}(f) \) is equal to the set \( \{(x, y) : x + y \leq d, x, y \geq 0\} \). The tropical version of the Bezout theorem in 2 dimensions is the following:
Theorem 4.27. Consider two generic tropical curves $C_1$ and $C_2$ in $\mathbb{R}^2$ of degree $d_1$ and $d_2$ respectively. Then the number of intersection points counted with multiplicity is equal to $d_1d_2$.

Proof. If the curve $C_i$ corresponds to the tropical polynomial $f_i$ then we know that the number of intersection between the curves is equal to

$$\int_{\mathbb{R}^2 \times \mathbb{R}^2} \text{dd}^\# f_1 \wedge \text{dd}^\# f_2.$$ 

By proposition 4.25 this number is equal to $n! \cdot V(\text{Newt}(f_1), \text{Newt}(f_2))$. But, if we let $S_d = \{(x,y) : x + y \leq d, x, y \geq 0\}$, then

$$V(S_{d_1}, S_{d_2}) = Vol(S_{d_1} + S_{d_2}) - Vol(S_{d_1}) - Vol(S_{d_2}) = 2^{-1}((d_1 + d_2)^2 - d_1^2 - d_2^2) = d_1d_2,$$

and we are done. \qed

In general, we consider equation (4.6) to be the general version of Bezout’s theorem. As another application, we show that the Proposition implies an interesting interplay between tropical and ordinary polynomials (cf. [13]): We begin by recalling Bernstein’s theorem.

Theorem 4.28. Let $P_1, ..., P_n$ be (generic) polynomials on $\mathbb{C}^n$. Then the number of solutions of the system $P_1 = ... = P_n = 0$ is equal to $n! \cdot V(\text{Newt}(P_1), ..., \text{Newt}(P_n))$, where $\text{Newt}(P_i)$ is the Newton polytope of $P_i$.

For each polynomial $P_i$, we associate the function $\tilde{f}_i(x) = \sup_{\xi \in \text{Newt}(P_i)} \xi \cdot x$, that is, the support function of $\text{Newt}(P_i)$. Clearly, $\tilde{f}_i$ belongs to $\mathcal{L}$ and is a tropical polynomial. Then Proposition 4.25 combined with Bernstein’s theorem says the following: the number (counted with multiplicities) of intersection points of the tropical hypersurfaces associated to $\tilde{f}_i$ is equal to the number of intersection points of the varieties $\{P_i = 0\} \subset \mathbb{C}^n$.
