ABSTRACT: We study elliptic fibrations that geometrically engineer an SU(2) × G₂ gauge theory realized by a Weierstrass model for the collision III+Iⁿˢ. We find all the distinct crepant resolutions of such a model and the flops connecting them. We compute the generating function for the Euler characteristic of the SU(2) × G₂-model. In the case of a Calabi-Yau threefold, we consider the compactification of M-theory and F-theory on an SU(2) × G₂-model to a five and six-dimensional supergravity theory with eight supercharges. By matching each crepant resolution with each Coulomb chamber of the five-dimensional theory, we determine the number of multiplets and compute the prepotential in each Coulomb chamber. In particular, we discuss the counting numbers of hypermultiplets in the presence of singularities. We discuss in detail the cancellation of anomalies of the six-dimensional theory.

1 Introduction and summary

Semi-simple Lie groups appear naturally in compactifications of M-theory and F-theory on elliptic fibrations [13, 14]. The Lie group is semi-simple (but non-simple) when the discriminant of the elliptic fibration contains at least two irreducible components \( \Delta_1 \) and \( \Delta_2 \) for which the dual graph of the singular fiber over the generic point of \( \Delta_i \) (\( i = 1, 2 \)) is reducible. These are called collisions of singularities and were first studied in string theory by Bershadsky and Johanson [14] using Miranda’s regularization of singular Weierstrass models [62]. If the fiber over the generic point of \( \Delta_i \) is a Kodaira fiber of type \( T_i \), the collision is called a \( T_1 + T_2 \)-model. If \( T_i \) has dual graph with Langlands dual \( e_i \), where \( g_i \) is the Lie algebra of a compact simply connected group \( G_i \) (assuming that the Mordell-Weil group is trivial), the model is also called a \( G_1 \times G_2 \)-model.

The aim of this article is to study the geometry and physics of \( SU(2) \times G_2 \)-models realized by the collision of singularities of type III + I ns.

In F-theory, we associate to an elliptic fibration of dimension three or higher a group \( G \) with Lie algebra \( g \), and a representation \( R \) of \( g \). In the case of an \( SU(2) \times G_2 \)-model, the representation \( R \) cannot be derived by the Katz-Vafa method (see section 4.1) but can be deduced using the method of saturations of weights obtained geometrically by intersection of fibral divisors and irreducible components of singular fibers over codimension-two points in the base (see section 4.2). The matter representation is then the following direct sum of irreducible representations\(^1\) (see section 4)

\[
R = (3, 1) \oplus (1, 14) \oplus (2, 7) \oplus (2, 1) \oplus (1, 7).
\]

(1.1)

In contrast to the traditional approach [21, 65, 68], we derive this representation \( R \) purely geometrically without using the anomaly cancellation conditions of the six-dimensional theory nor a dual heterotic model. This method is valid for both five and six-dimensional theories and has the advantage to work in situations where the Katz-Vafa method is not applicable (see section 4.1). In the 5d theory, it also has the benefit of not depending on the existence of a 6d uplift. For the six-dimensional theory, we check explicitly that the anomaly cancellation conditions are satisfied. We also point out that the fundamental representation \( (1, 7) \) is a frozen representation when the curve supporting \( G_2 \) is a \(-3\)-curve intersecting the curve supporting \( SU(2) \) transversally and at a unique point. This explains the absence of the representation \( (1, 7) \) in [21]. The number of charged hypermultiplets in each of these representations are given in equation (1.2), which generalizes the spectrum \( \frac{1}{2}(2, 7) \oplus \frac{1}{2}(2, 1) \) expected in a six-dimensional theory when a \( SU(2) \times G_2 \)-model is locally

\(^1\)We write the tensor product of a representation \( r_1 \) of \( SU(2) \) and \( r_2 \) of \( G_2 \) as \( (r_1, r_2) \). We follow the usual tradition in physics of writing a representation by its dimension as there is no room for ambiguity with the representations used in this paper. The \( 2 \) and the \( 3 \) of \( SU(2) \) are respectively the fundamental and the adjoint representation of \( SU(3) \); the \( 7 \) and the \( 14 \) of \( G_2 \) are respectively the fundamental and the adjoint representation of \( G_2 \). The representations \((3, 1), (1, 14), \) and \((1, 7) \) are real while the representation \((2, 1) \) and \((2, 7) \) are pseudo-real.
defined at the collision of a $-2$-curve and a $-3$-curve intersecting transversally at one point and supporting respectively a $\text{SU}(2)$ and a $G_2$ Lie group \cite{21, 65}.

The III + $I_0^{\text{ns}}$-model was first discussed in string theory in the early days of F-theory in \cite{14, 20, 21} and was already considered in mathematics in the early 1980’s by Miranda \cite{62}. The $\text{SU}(2) \times G_2$-model appears naturally in the study of non-Higgsable clusters \cite{65}. Over non-compact bases, collisions of singularities are used to classify 6d $\mathcal{N} = (1,0)$ superconformal field theories using elliptic fibrations. For example, for elliptic threefolds, such a non-Higgsable model is produced when the discriminant locus contains two rational curves with self-intersection $-3$ and $-2$ intersecting transversally or three rational curves which form a chain of curves intersecting transversally at a point with self-intersections $(-3, -2, -2)$ \cite{15, 26, 51, 65}.

Surprisingly, despite receiving a significant amount of attention in the last few years for their role in the study of superconformal field theories, many properties of the III + $I_0^{\text{ns}}$ model remain unknown. For example, the structure of its Coulomb branch is not known. We show that the Coulomb branch consists of four chambers arranged as a Dynkin diagram of type $A_4$ illustrated on figure 1. We also compute the four corresponding prepotentials. Geometrically, each Coulomb chamber corresponds to a different crepant resolution of the Weierstrass model. We present for the first time these four crepant resolutions, we study their fiber structures (see figures 3 and figures 12–16) and determine the triple intersection numbers of their fibral divisors in theorem 2.13. By comparing the triple intersection numbers with the prepotential, we determine the number of charged hypermultiplets in a five-dimensional supergravity theory defined by a compactification of M-theory on a threefold given by an $\text{SU}(2) \times G_2$-model. We then show that these numbers are also consistent with an anomaly-free six-dimensional theory, which corresponds to a compactification of F-theory on the same variety.

We work with an arbitrary base of dimension $n$ and specialize to the case of Calabi-Yau threefolds only when necessary to connect with the physics. Since the resolution of singularities is a local process, the base can be either compact or non-compact. The compactness of the base will matter when considering anomaly cancellations.

Let $S$ and $T$ be the divisors supporting $\text{SU}(2)$ and $G_2$ respectively. Let $\Delta'$ be the third component of the discriminant locus. Then, the number of charged hypermultiplets are (see section 5)

\begin{equation}
\begin{align*}
n_{2,7} &= \frac{1}{2} S \cdot T, \\
n_{3,1} &= g(S), \\
n_{2,1} &= -S \cdot \left( 8K + 2S + \frac{7}{2}T \right), \\
n_{1,14} &= g(T), \\
n_{1,7} &= -T \cdot (5K + 2T + S).
\end{align*}
\end{equation}

The numbers $n_{2,7}$ and $n_{2,1}$ can be half-integer numbers since the representations $(2, 7)$ and $(2, 1)$ are both pseudo-real and thus can have half-hypermultiplets charged under them. As a sanity check, when $S$ and $T$ are respectively $-2$ and $-3$-curves intersecting transversally at a unique point, we retrieve the familiar spectrum (see remark 1.1 below)

$$R = \frac{1}{2}(2, 7) \oplus \frac{1}{2}(2, 1).$$
It is also useful to express $n_{2,1}$ and $n_{1,7}$ in terms of the genus $^2$ and the self-intersection of $T$ and $S$

$$n_{2,1} = 16 - 16g(S) + 6S^2 - \frac{7}{2}S \cdot T, \quad n_{1,7} = 10 - 10g(T) + 3T^2 - S \cdot T. \quad (1.3)$$

The Hodge numbers of a compact Calabi-Yau threefold that is an SU(2) $\times$ G$_2$-model are (see section 2.4)

$$h^{1,1}(Y) = 14 - K^2, \quad h^{2,1}(Y) = 29K^2 + 15K \cdot S + 24K \cdot T + 3S^2 + 6S \cdot T + 6T^2 + 14, \quad (1.4)$$

where $K$ is the canonical class of the base of the elliptic fibration $Y$. In the six-dimensional supergravity theory, using Sadov’s techniques [68], we check that anomalies are canceled explicitly by the Green-Schwarz-Sagnotti-West mechanism. The anomaly polynomial $I_8$ factors as a perfect square:

$$I_8 = \frac{1}{2} \left( \frac{1}{2} \text{tr} R^2 + 2 \text{str}_2 F_1^2 + T \text{tr}_7 F_2^2 \right)^2,$$

where $F_1$ and $F_2$ are the field strengths for SU(2) and G$_2$ respectively.

**Remark 1.1.** the SU(2) $\times$ G$_2$-model, the fundamental representation $(1,7)$ is often ignored because it is localized away from the collision of the curves supporting G$_2$ and SU(2). However, it is expected from the study of the G$_2$-model as discussed in detail [33]. In the case of an SU(2) $\times$ G$_2$-model for which SU(2) is supported on a curve $S$ and G$_2$ is supported on a $-3$-curve $T$, such that $S$ and $T$ intersect transversally at one point, we see using equation (1.3) that the fundamental representation $(1,7)$ is a frozen representation: there are vertical curves carrying the weights of such a representation, whereas the number of hypermultiplets $n_{1,7}$ charged under that representation vanishes. If $S$ and $T$ are smooth rational curves, the adjoint representation is frozen ($n_{3,1} = n_{1,14} = 0$). If $T$ is and $S$ are respectively $-3$ and $-2$ curves intersecting transversally at a point, we retrieve the famous spectrum $\frac{1}{2}(2,7) \oplus \frac{1}{2}(2,1)$ first observed in [21] by Candelas, Perevalov and Rajesh; and popularized in recent years with the study of non-Higgsable clusters [65].

**Remark 1.2.** In an $\mathcal{N} = (1,0)$ six-dimensional theory, the cancellations of anomalies of an SU(2) $\times$ G$_2$-model show that the number of hypermultiplets charged in the representation $(2,1)$ receives a contribution $S \cdot T/2$, which suggests that there are curves carrying the weights of that representation at the intersection of $S$ and $T$. The formula for $n_{2,1}$ derived using anomaly cancellations of the six-dimensional theory is consistent with the triple intersection numbers of the SU(2) $\times$ G$_2$-model. However, we do not see any evidence of such a representation in the weights carried by curves composing the singular fibers over $S \cap T$. They carry instead the weights of the representation $(2,7)$ which contain as a subset the weights of the representation $(2,1)$. We note that if $S$ and $\Delta'$ have a non-empty intersection, there are rational curves carrying the weight of the representation $(2,1)$ away from the intersection of $S$ and $T$, exactly over the points where the fiber III degenerates to a fiber of type IV. We discuss this further in section 6.

$^2$We recall that the genus $g$ of a curve $C$ in a surface of canonical class $K$ satisfies the relation $2 - 2g = -C \cdot K - C^2$. 

---

4
1.1 Outlook

In the rest of the introduction, we will motivate the model by an argument of simplicity, spell out the questions that we aim to answer, and summarize the key results of the paper for the convenience of the reader. We discuss the definition of the model, explain the structure of its Coulomb branch (and the geometric derivation of its matter content), present the non-Kodaira fibers produced by the four crepant resolutions of the SU(2) × G₂-model, and discuss aspects of compactifications of M-theory and F-theory on an SU(2) × G₂-model that is a Calabi-Yau threefold. We also summarize the counting of its charged hypermultiplets, and the cancellations of anomalies of the six-dimensional theory.

The rest of the paper is a detailed development of these points and is structured as follows. In section 2, we collect our geometric results. In section 2.1, we introduce the model that we study in this paper, define its Weierstrass model, its crepant resolutions, compute the Euler characteristic of the crepant resolutions and the triple intersection of the fibral divisors. In the case of a Calabi-Yau threefold, we also compute the Hodge numbers. We compute the adjacency graph of the hyperplane arrangement associated with an SU(2) × G₂-model, and finally match the structure of the hyperplane arrangement with the flopping curves of the crepant resolutions. In section 5, we study the consequences of our geometric results for the physics of F-theory and M-theory compactified on an SU(2) × G₂-model. We discuss the subtleties of counting the number of hypermultiplets in presence of singularities in section 6.

1.2 The simplest collisions of singularities

The SU(2) × G₂-model is an important model not only in F-theory and M-theory but also in birational geometry. Mathematically, it will appear naturally as a key model of collision of singularities solely based on the simplicity of its fiber structure. It is natural to organize elliptic fibrations describing collision of singularities by the rank of the associated Lie algebra derived from F-theory. Geometrically, the rank of G counts the number of fibral divisors produced by a crepant resolution and relates to the relative Picard number of the elliptic fibration via the Shioda-Tate-Wazir theorem [74, corollary 4.1].

If we organize the collisions of singularities by the rank of the associated Lie algebra, the simplest collisions will correspond to the collision of two singular fibers with dual graphs \( \tilde{A}_1 \) and the associated gauge group is either

\[
\text{Spin}(4) = \text{SU}(2) \times \text{SU}(2) \quad \text{or} \quad \text{SO}(4) = \text{SU}(2) \times \text{SU}(2)/(\mathbb{Z}/2\mathbb{Z}),
\]

when the Mordell-Weil group is trivial or \( \mathbb{Z}/2\mathbb{Z} \), respectively. These models are studied in detail in [35].

The next simplest case has an associated Lie group of the type SU(2) × G, where G is a simple Lie group of rank two. There are three possibilities when G is a compact simple and simply connected Lie group of rank two:

\[
\text{SU}(2) \times \text{SU}(3), \quad \text{SU}(2) \times \text{Sp}(4), \quad \text{or} \quad \text{SU}(2) \times G_2.
\]

The SU(2) × SU(3)-model is interesting for its connection to the non-Abelian sector of the Standard Model and is studied in [36]. The others are QCD-like theories obtained by
Table 1. Simplest collisions of singularities. We assume that $G$ is a semi-simple non-simply connected group of rank 2 or 3. The Spin(4) and SO(4)-models are studied in [35]. The $G = SU(2) \times SU(3)$ is studied in [36], the $G = SU(2) \times Sp(4)$ is studied in [39], and the $G = SU(2) \times G_2$ is the subject of the present paper.

Replacing $SU(3)$ by another simple and simply connected group of rank two. The $SU(2) \times Sp(4)$-model is studied in [39]. The group $G_2$ is the smallest simply connected Lie group with a trivial center and all its representation are real. The $G_2$-model is analyzed in detail in [33].

In Miranda’s regularization, the collisions of singularities are organized by their values of the $j$-invariant as only Kodaira fibers sharing the same $j$-invariant are considered in Miranda’s model [62]. The $III + I_0^{ns}$ is a collision of fibers for which the $j$-invariant is 1728. The fiber over the generic point of the collision is a non-Kodaira fiber composed of a chain of five rational curves intersecting transversally with multiplicities 1-2-3-2-1. This fiber is a contraction of a Kodaira fiber of type $III^*$ whose dual graph is the affine Dynkin diagram of type $\tilde{E}_7$.

1.3 Canonical problems in F/M-theory

A standard set of questions in F-theory and M-theory compactifications on an elliptically fibered Calabi-Yau threefold $Y$ are the following [4, 17, 29, 41, 44]:

(i) **Birational geometry.** Does the singular Weierstrass model have a crepant resolution? How many crepant resolutions does it have? How are they flop-connected with each other? What is the graph of the flops?

(ii) **Fiber geometry.** What is the fiber structure of each crepant resolution? What are the vertical curves composing the singular fibers? What are their weights? What representation do they carry?

(iii) **Coulomb branch and charged hypermultiplets.** What is the structure of the Coulomb branch of the five-dimensional $\mathcal{N} = 1$ theory with Lie group $g$ and representation $R$ geometrically engineered by an elliptic fibration $Y$? How many hypermultiplets transform under each of the irreducible components of $R$? Can we completely fix the number of charged multiplets by comparing the triple intersection numbers and the prepotentials?

(iv) **Anomaly cancellations and uplift.** Is the five-dimensional theory always compatible with an uplift to an anomaly free six-dimensional theory? What are the conditions
to ensure cancellations of anomalies of a six-dimensional $\mathcal{N} = (1,0)$ supergravity obtained by compactification of F-theory on $Y$? Can we fix the number of multiplets by the six-dimensional anomaly cancellation conditions?

(v) **Topological invariants.** What is the Euler characteristic of a crepant resolution? What are the Hodge numbers of $Y$? What are the triple intersection numbers in each Coulomb branch?

These questions are closely related to each other and have been addressed recently for many geometries, such as the $G_2$, Spin$(7)$, and Spin$(8)$-models [33], F$_4$-models [38], SU$(n)$-models [41–44, 49], and also for (non-simply connected) semi-simple groups such as the SO$(4)$ and Spin$(4)$-models [35], SU$(2)\times$SU$(4)$, (SU$(2)\times$SU$(4))/\mathbb{Z}_2$, SU$(2)\times$Sp$(4)$, and (SU$(2)\times$Sp$(4))/\mathbb{Z}_2$-models [39].

We answer these canonical questions for the SU$(2)\times G_2$-model. We first do not restrict ourselves to Calabi-Yau threefolds, but discuss the crepant resolutions and the Euler characteristic without fixing the base of the fibration in the spirit of [2, 3, 37, 42, 43]. The computation of topological invariants such as the triple intersection numbers and the Euler characteristic are streamlined by recent pushforward theorems [34].

For recent works in F-theory and birational geometry in physics, see for example [5, 6, 11, 16, 24, 25, 54, 57, 59], see also the recent review on F-theory [73] and reference within. We refer to [52] for a review of six-dimensional theories.

1.4 **Defining the SU$(2)\times G_2$-model**

Given a morphism $X \to B$ and an irreducible divisor $S$ of $B$, the generic fiber over $S$ is by definition the fiber over its generic point $\eta$. Such a fiber $X_\eta$ is a scheme over the residue field $\kappa$ of $\eta$. The residue field $\kappa$ is not necessarily geometrically closed. Some components of $X_\eta$ can be irreducible as a $\kappa$-scheme but will decompose further after a field extension $\kappa \to \kappa'$. We denote the cyclic group (resp. the group of permutations) of $n$ distinct elements by $\mathbb{Z}_n$ (resp. $S_n$). In the case of a flat elliptic fibration, the Galois group of the minimal field extension that allows all the irreducible components of $X_\eta$ to be geometrically irreducible is $\mathbb{Z}_2$ for all non-split Kodaira fibers with the exception of $I_0^*\ell$ for which the Galois group could also be $S_3$ or $\mathbb{Z}_3$ [33].

Kodaira fibers classify geometric generic fibers of an elliptic fibration (the fiber defined over the algebraic closure of the residue field). The generic fiber (defined over the residue field $\kappa$) is classified by the Kodaira type of the corresponding geometric generic fiber together with the Galois group of the minimal field extension necessary to make all irreducible components of the fiber geometrically irreducible. The Galois group is always $\mathbb{Z}_2$ unless in the case of the fiber $I_0^*$ where it can also be $\mathbb{Z}_3$ or $S_3$. Thus, there are two distinct fibers with dual graph $G_2^*$ as the Galois group of an irreducible cubic can be the symmetric group $S_3$ or the cyclic group $\mathbb{Z}_3$ [33]. When we specify the type of Galois group, we write $I_0^{*\text{ns}}$ as $I_0^{*S_3}$ or $I_0^{*\mathbb{Z}_3}$. An $I_0^{*\mathbb{Z}_3}$-model is very different from an $I_0^{*S_3}$-model already at the level of the fiber geometry as discussed in [33] and reflected in the tables of section §3.5 of the present paper. Elliptically fibered threefolds corresponding to an $I_0^{*\mathbb{Z}_3}$-model or an $I_0^{*S_3}$-model give the same gauge group, matter representations and number of charged
hypermultiplets. The $I_0^{S_3}$-model is the more general one and behaves better with respect to resolutions of singularities. We refer to [33] for more information. In the rest of the paper, when we write $I_0^{ns}$ without further explanation, we always mean the generic $I_0^{S_3}$.

There are five different Kodaira fibers with dual graph $\tilde{A}_1$ and thus producing an $SU(2)$, namely $I_0^{S_3}$, $I_2$, $III$, $IV^{ns}$, and $I_3^{ns}$. The $SU(2) \times G_2$ could be realized by any of the following ten models

$$I_2^{ns} + I_0^{ns}, \; I_3^{ns} + I_0^{ns}, \; III + I_0^{ns}, \; I_3^{ns} + I_0^{ns}, \; or \; IV^{ns} + I_0^{ns},$$

where $I_0^{ns}$ could be either $I_0^{Z_3}$ or $I_0^{S_3}$. For example, the non-Higgsable models of type $SU(2) \times G_2$ studied in the literature are typically of the type $I_3^{S_3}$.

A Weierstrass model for the collision $III + I_0^{S_3}$ is [62]

$$III + I_0^{S_3} : \quad y^2z = x^3 + f s t^2 x z^2 + g s^2 t^3 z^3.$$  \hspace{1cm} (1.5)

The discriminant locus is composed of three irreducible components $S$, $T$, and $\Delta'$:

$$\Delta = s^3 t^6 (4 f^3 + 27 g^2 s),$$  \hspace{1cm} (1.6)

where $S = V(s)$ and $T = V(t)$ are two smooth Cartier divisors supporting respectively the fiber of type $III$ and of type $I_0^{ns}$. We assume that $S$ and $T$ intersect transversally. The fiber over the generic point of the leftover discriminant $\Delta' = 4 f^3 + 27 g^2 s$ is a nodal curve (Kodaira type $I_1$). Following Tate’s algorithm, the type of the decorated Kodaira fibers depends on the Galois group of the associated associated cubic polynomial

$$P(q) = q^3 + f s q + g s^2.$$  \hspace{1cm} (1.7)

Assuming that $P(q)$ is irreducible, the Galois group is $Z_3$ if the discriminant of $P(q)$, $\Delta(P) = s^3 (4 f^3 + 27 g^2 s)$, is a perfect square in the residue field of the generic point of $T$ [33]. A simple way to have a $Z_3$ Galois group is to increase the valuation of $f$ along $T$ [33]:

$$III + I_0^{Z_3} : \quad y^2z = x^3 + f s t^2 x z^2 + g s^2 t^3 z^3.$$  \hspace{1cm} (1.8)

In this case, the $j$-invariant will be zero over the generic point of $T$ in contrast to the case of equation (1.5) where the $j$-invariant is $1728$ on both $S$ and $T$. The fact that the Galois group of $P(q)$ is $Z_3$ is clear as it now takes the form

$$P(q) = q^3 + g s^2.$$  \hspace{1cm} (1.9)

### 1.5 Representations, Coulomb branches, hyperplane arrangements, and flops

In F-theory, we associate to an elliptic fibration a group $G$ with Lie algebra $\mathfrak{g}$, and a representation $\mathbf{R}$ of $\mathfrak{g}$. In the case of an $SU(2) \times G_2$-model, the representation $\mathbf{R}$ is the direct sum of the following irreducible representations (see section 3)

$$\mathbf{R} = (3, 1) \oplus (1, 14) \oplus (2, 7) \oplus (2, 1) \oplus (1, 7).$$  \hspace{1cm} (1.10)

The $(3, 1)$ is the adjoint representation of $SU(2)$ and the $(1, 14)$ is the adjoint representation of $G_2$. The $(2, 7)$ is the bifundamental representation of $SU(2) \times G_2$ supported at the
The chamber structure of $I(A_1 \oplus g_2, (2, 7))$ and its adjacency graph. This also represents the structure of the extended Kähler cone of an SU(2)×G_2-model. Replacing $(2, 7)$ with $R = (3, 1) \oplus (1, 14) \oplus (2, 7) \oplus (2, 1) \oplus (1, 7)$ does not change the adjacency graph since the adjoint and fundamental representations do not intersect the interior of the Weyl chamber of $A_1 \oplus g_2$. The interior walls are given by the weights $\varpi_5^{(2,7)} = (1; -2, 1)$, $\varpi_6^{(2,7)} = (1; 1, -1)$, and $\varpi_7^{(2,7)} = (1; -1, 0)$.

The study of the Coulomb branch of the gauge theory geometrically engineered by an elliptic fibration is the study of the minimal models over the Weierstrass model and how they flop to each other. This can also be described through the hyperplane arrangement $I(g, R)$ with hyperplanes that are kernels of the weights of $R$ restricted inside the dual fundamental Weyl chamber of $g$ [31, 32, 42, 43]. In the case of the SU(2)×G_2-model, it is interesting to notice that the generic SU(2)-model and G_2-model do not have any flops [33, 42]. However, the SU(2)×G_2-model has the bifundamental representation $(2, 7)$, which contains several weights whose kernels are hyperplanes intersecting the open dual Weyl chamber of $A_1 \oplus g_2$ and giving four chambers, whose incidence graph is a chain illustrated in figure 1. In this way, we see that the hyperplane arrangement $I(g, R)$ does not care about the fundamental and adjoint representations, namely $(2, 1)$, $(1, 7)$, $(3, 1)$, and $(1, 14)$, since only the weights $\varpi$ of the bifundamental representation $(2, 7)$ define the hyperplanes $\varpi^\perp$ intersecting the interior of the dual Weyl chamber of $g = A_1 \oplus g_2$; hence, it is enough to study only $I(A_1 \oplus g_2, (2, 7))$.

1.6 Non-Kodaira fibers

Three rational curves that are transverse to each other and meet at the same point (such as the Kodaira fiber of type IV) are represented by three nodes connected to the same point. We write $\tilde{G}_2$ and $\tilde{G}_2^\vee$ for the affine Dynkin diagram of type $G_2$ and its Langlands dual, respectively. In Kac’s notation [55], they are denoted respectively $G_2^{(1)}$ and $D_4^{(3)}$. The dual graph of the fiber $I_0^{\text{ns}}$ is of type $G_2^\vee$ and not $G_2$ as often stated in the F-theory literature but clear from figure 2.

There are many examples of non-Kodaira fibers in the literature [22, 30, 44, 50, 62, 71]. Over the generic point of $s = f = g = 0$, the III-model has a non-Kodaira fiber that
Figure 2. Conventions for dual graphs. The black node represents the extra node of the affine Dynkin diagram. The affine Dynkin diagrams $\tilde{G}_2$ and $G_2^t$ are Langlands dual of each other. But only $G_2^t$ is the dual graph of a singular fiber over the generic point of a component of the discriminant locus of an elliptic fibrations. Specifically, $G_2^t$ is the dual graph of the fiber $I_0^{ns}$.

Figure 3. Non-Kodaira Fibers for the SU(2) $\times G_2$-model. On the left, we have the generic fiber over the collision $S \cap T$. On the right, we have its specialization when $f = 0$. This specialization is seen only when the base is at least a threefold or if we change the valuation of $t$ along $a_4$.

are contractions of a fiber of type $I_0^s$. The $G_2$-model has non-Kodaira fibers that are contractions of an $I_1^s$ and a $IV^*$ fiber [33]. At the collision $III+I_0^{ns}$, we get a non-Kodaira fiber that is an incomplete $III^*$ and specializes further to an incomplete $II^*$. The fibers found by Miranda at the collision $III+I_0^{ns}$ match the ones we find in the resolution I for the generic fiber over $S \cap T$. Miranda has already noticed in [62] that the non-Kodaira fibers of Miranda’s model were always contractions of Kodaira fibers. The same is true for Miranda’s models of arbitrary dimension [71] and for flat elliptic threefolds [22].

1.7 Compactifications of F-theory and M-theory on an SU(2) $\times G_2$-model

The crepant resolutions of the Weierstrass model of an SU(2) $\times G_2$-model are listed in equation (2.2). The Euler characteristic of an SU(2) $\times G_2$-model obtained by one of these
crepant resolutions is derived in theorem 2.5. As explained in the previous subsections, the hyperplane arrangements $I(g, R)$ has four chambers whose adjacency graph is represented in figure 1. Each chamber corresponds to a specific crepant resolution that we determine explicitly. While three of the crepant resolutions (namely, Resolutions I, III, and IV) are obtained by blowing up smooth centers, one (resolution II) is defined by a blowup with a non-smooth center. For each chamber, we match an explicit crepant resolution of the Weierstrass model, so that the graph of flops matches the adjacency graph of the hyperplane arrangement.

We analyze the physics of compactifications of M-theory and F-theory on elliptically fibered Calabi-Yau threefolds corresponding to SU(2) $\times$ G$_2$-models. These give five- and six-dimensional gauged supergravity theories with eight supercharges with the gauge group SU(2)$\times$G$_2$. We determine the matter content of these compactifications and study anomaly cancellations of the six-dimensional theory and their Chern-Simons terms.

In the five-dimensional theory [19, 53], the structure of the Coulomb chambers is isomorphic to the adjacency graph of the hyperplane arrangement $I(g, R)$. We compute the one-loop prepotential in each Coulomb chamber as a function of the number of hypermultiplets in each irreducible representations that add up to $R$. The Chern-Simons couplings are computed geometrically as triple intersection numbers of the fibral divisors (see theorem 2.13). We match the triple intersection polynomial with the prepotential to obtain constraints on the number of charged hypermultiplets (see equation (5.2)). In many cases, such a method will completely fix the number of multiplets, but here, the numbers $n_{2,1}$ and $n_{3,1}$ are left unfixed but related by a linear relation. However, they are completely fixed once we use Witten’s genus formula, which asserts that the number of multiplets in the adjoint representation is given by the genus of curve supporting the gauge group [75].

In the six-dimensional theory obtained by compactification of F-theory on an SU(2) $\times$ G$_2$-model, we solve the anomaly equations and deduce the number of hypermultiplets. They match perfectly what we found independently in the M-theory compactification (see equation (5.28)).

2 Geometric results

In this section, we collect key geometric results on SU(2) $\times$ G$_2$-models.

2.1 Geometric description

We consider the following defining equation for an SU(2) $\times$ G$_2$-model:

$$\text{III} + I_0^{\text{ns}} : \ y^2z = x^3 + f s t^2 x z^2 + g s^2 t^3 z^3. \quad (2.1)$$

We assume that the coefficients $f$ and $g$ are algebraically independent and $S = V(s)$ and $T = V(t)$ are smooth divisors intersecting transversally. The Kodaira fiber over the generic point of $S$ (resp. $T$) has a respective dual graph $\tilde{A}_1$ (resp. $\tilde{G}_2$).
2.2 Crepant resolutions

We use the following convention. Let $X$ be a nonsingular variety. Let $Z \subset X$ be a complete intersection defined by the transverse intersection of $r$ hypersurfaces $Z_i = V(g_i)$, where $g_i$ is a section of the line bundle $\mathcal{I}_i$ and $(g_1, \ldots, g_r)$ is a regular sequence. We denote the blowup of a nonsingular variety $X$ along the complete intersection $Z$ by

$$X \leftarrow (g_1, \ldots, g_r|e_1) \tilde{X}.$$ 

The exceptional divisor is $E_1 = V(e_1)$. We abuse notation and use the same symbols for $x, y, s, e_i$ and their successive proper transforms. We also do not write the obvious pullbacks.

Each of the following four sequences of blowups is a different crepant resolution of the $SU(2) \times G_2$-model given by the Weierstrass model of equation (2.1).

Resolution I: $X_0 \leftarrow (x, y, s|e_1) X_1 \leftarrow (x, y, t|w_1) X_2 \leftarrow (y, w_1|w_2) X_3$,

Resolution II: $X_0 \leftarrow (x, y, p_0|p_1) X_1 \leftarrow (y, p_1, t|w_1) X_2 \leftarrow (p_0, t|w_2) X_3$,

Resolution III: $X_0 \leftarrow (x, y, t|w_1) X_1 \leftarrow (x, y, s|e_1) X_2 \leftarrow (y, w_1|w_2) X_3$,

Resolution IV: $X_0 \leftarrow (x, y, t|w_1) X_1 \leftarrow (y, w_1|w_2) X_2 \leftarrow (x, y, s|e_1) X_3$.

These are embedded resolutions and $X_0 = \mathbb{P}(\mathcal{O}_B \oplus \mathcal{L}^\oplus 2 \oplus \mathcal{L}^\oplus 3)$.

2.3 Intersection theory

All of our intersection theory computations come down to the following three theorems. The first is a theorem of Alu which gives the Chern class after a blowup along a local complete intersection. The second theorem is a pushforward theorem that provides a user-friendly method to compute invariants of the blowup space in terms of the original space. The last theorem is a direct consequence of functorial properties of the Segre class, and gives a simple method to pushforward analytic expressions in the Chow ring of a projective bundle to the Chow ring of its base.

**Theorem 2.1** (Alu, [1, Lemma 1.3]). Let $Z \subset X$ be the complete intersection of $d$ nonsingular hypersurfaces $Z_1, \ldots, Z_d$ meeting transversally in $X$. Let $f : \tilde{X} \rightarrow X$ be the blowup of $X$ centered at $Z$. We denote the exceptional divisor of $f$ by $E$. The total Chern class of $\tilde{X}$ is then:

$$c(T\tilde{X}) = (1 + E) \left( \prod_{i=1}^d \frac{1 + f^*Z_i - E}{1 + f^*Z_i} \right) f^*c(TX).$$

**Theorem 2.2** (Esole-Jefferson-Kang, see [34]). Let the nonsingular variety $Z \subset X$ be a complete intersection of $d$ nonsingular hypersurfaces $Z_1, \ldots, Z_d$ meeting transversally in
$X$. Let $E$ be the class of the exceptional divisor of the blowup $f : \tilde{X} \to X$ centered at $Z$. Let $\tilde{Q}(t) = \sum_a f^* Q_a t^a$ be a formal power series with $Q_a \in A_*(X)$. We define the associated formal power series $Q(t) = \sum_a Q_a t^a$, whose coefficients pullback to the coefficients of $\tilde{Q}(t)$. Then the pushforward $f_* \tilde{Q}(E)$ is

$$f_* \tilde{Q}(E) = \sum_{\ell=1}^d Q(Z_\ell) M_\ell, \quad \text{where} \quad M_\ell = \prod_{m=1}^d \frac{Z_m}{Z_m - Z_\ell}.$$

**Theorem 2.3** (See [34] and [2, 3, 37, 46]). Let $L$ be a line bundle over a variety $B$ and $\pi : X_0 = \mathbb{P}[\mathcal{O}_B \oplus \mathcal{L}^\otimes 2 \oplus \mathcal{L}^\otimes 3] \to B$ a projective bundle over $B$. Let $\tilde{Q}(t) = \sum_a \pi^* Q_a t^a$ be a formal power series in $t$ such that $Q_a \in A_*(B)$. Define the auxiliary power series $Q(t) = \sum_a Q_a t^a$. Then

$$\pi_* \tilde{Q}(H) = -2 \frac{Q(H)}{H^2} \bigg|_{H=-2L} + 3 \frac{Q(H)}{H^2} \bigg|_{H=-3L} + \frac{Q(0)}{6L^2},$$

where $L = c_1(\mathcal{L})$ and $H = c_1(\mathcal{O}_{X_0}(1))$ is the first Chern class of the dual of the tautological line bundle of $\pi : X_0 = \mathbb{P}(\mathcal{O}_B \oplus \mathcal{L}^\otimes 2 \oplus \mathcal{L}^\otimes 3) \to B$.

### 2.4 Euler characteristics and Hodge numbers

In the spirit of [34], the Euler characteristic depends only on the sequence of blowups. Using $p$-adic integration and the Weil conjecture, Batyrev proved the following theorem.

**Theorem 2.4** (Batyrev, [10]). Let $X$ and $Y$ be irreducible birational smooth $n$-dimensional projective algebraic varieties over $\mathbb{C}$. Assume that there exists a birational map $\varphi : X \to Y$ that does not change the canonical class. Then $X$ and $Y$ have the same Betti numbers.

Batyrev’s result was strongly inspired by string dualities, in particular by the work of Dixon, Harvey, Vafa, and Witten [28]. As a direct consequence of Batyrev’s theorem, the Euler characteristic of a crepant resolution of a variety with Gorenstein canonical singularities is independent on the choice of a crepant resolution. We identify the Euler characteristic as the degree of the total (homological) Chern class of a crepant resolution $f : \tilde{Y} \to Y$ of a Weierstrass model $Y \to B$:

$$\chi(\tilde{Y}) = \int c(\tilde{Y}).$$

We then use the birational invariance of the degree under the pushforward to express the Euler characteristic as a class in the Chow ring of the projective bundle $X_0$. We subsequently push this class forward to the base to obtain a rational function depending only on the total Chern class of the base $c(B)$, the first Chern class $c_1(\mathcal{L})$, and the class $S$ of the divisor in $B$:

$$\chi(\tilde{Y}) = \int_B \pi_* f_* c(\tilde{Y}).$$

In view of theorem 2.4, this Euler characteristic is independent of the choice of a crepant resolution.
Theorem 2.5. The generating polynomial of the Euler characteristic of an SU(2) × G2-model obtained by a crepant resolution of a Weierstrass model given in section 2.2:
\[ \chi(Y) = 6 \frac{S^2 - 2L - 3SL + 2(S^2 - 3SL + S - 2L)T + (3S + 2)T^2}{(1 + S)(1 + T)(-1 - 6L + 2S + 3T)} c(TB). \]

Proof. The total Chern class of \( X_0 = \mathbb{P}_B[\mathcal{O}_B \oplus \mathcal{L} \oplus \mathcal{L} \oplus \mathcal{L} \oplus \mathcal{L}] \) is
\[ c(TX_0) = (1 + H)(1 + H + 2\pi^*L)(1 + H + 3\pi^*L)\pi^*c(TB). \]
where \( L = c_1(\mathcal{L}) \) and \( H = c_1\left(\mathcal{O}_{X_0}(1)\right) \). The class of the Weierstrass equation is \( [Y_0] = 3H + 6L \). Since all the resolutions are crepant, it is enough to do the computation in one of them. We consider Resolution I. We denote the blowups by
\[ f_1 : X_1 \to X_0, \quad f_2 : X_2 \to X_1, \quad \text{and} \quad f_3 : X_3 \to X_2, \]
where \( E_1, W_1 \) and \( W_2 \) are respectively the classes of the first, second, and third blowups. The center of the three blowups have respectively classes:
\[ Z_1^{(1)} = H + 2\pi^*L, \quad Z_2^{(1)} = H + 3\pi^*L, \quad Z_3^{(1)} = \pi^*S, \]
\[ Z_1^{(2)} = f_1^*H + 2f_1^*\pi^*L - E_1, \quad Z_2^{(2)} = f_1^*H + 3f_1^*\pi^*L - E_1, \quad Z_3^{(2)} = f_1^*\pi^*T, \]
\[ Z_1^{(3)} = f_1^*f_2^*H + 3f_1^*f_2^*\pi^*L - f_2^*E_1 - W_1, \quad Z_2^{(3)} = W_1. \]
The successive blowups give (see theorem 2.1)
\[ c(TX_1) = \frac{(1 + E_1)(1 + Z_1^{(1)} - E_1)(1 + Z_2^{(1)} - E_1)(1 + Z_3^{(1)} - E_1)}{(1 + Z_1^{(1)})(1 + Z_2^{(1)})(1 + Z_3^{(1)})} f_1^{*}c(TX_0), \]
\[ c(TX_2) = \frac{(1 + W_1)(1 + Z_1^{(2)} - W_1)(1 + Z_2^{(2)} - W_1)(1 + Z_3^{(2)} - W_1)}{(1 + Z_1^{(2)})(1 + Z_2^{(2)})(1 + Z_3^{(2)})} f_2^{*}c(TX_1), \]
\[ c(TX_3) = \frac{(1 + W_2)(1 + Z_1^{(3)} - W_2)(1 + Z_2^{(3)} - W_2)}{(1 + Z_1^{(3)})(1 + Z_2^{(3)})} f_3^{*}c(TX_2). \]
After the first blowup, the proper transform of \( Y_0 \) is of class \( Y_1 = f_1^*Y_0 - 2E_1 \). After the second blowup, the proper transform of \( Y_1 \) is of class \( Y_2 = f_2^*Y_1 - 2W_1 \). And finally, after the third blowup, the proper transform of \( Y_2 \) is \( Y = f_3^*Y_2 - W_2 \). Altogether, we have
\[ [Y] = (f_3^*f_2^*f_1^*)(3H + 6\pi^*L) - 2f_3^*f_2^*E_1 - 2f_3^*W_1 - W_2 \cap [X_3]. \]
We also have that \( c_1(X_3) = f_3^*f_2^*f_1^*c_1(X_0) - 2f_3^*f_2^*E_1 - 2f_3^*W_1 - W_2 \). Hence \( c_1(Y) = f_3^*f_2^*f_1^*c_1(Y_0) \), which prove that the resolution is crepant. The total Chern class of \( Y \) is (see theorem 2.1)
\[ c(TY) \cap [Y] = \frac{f_3^*f_2^*f_1^*(3H + 6\pi^*L) - 2f_3^*f_2^*E_1 - 2f_3^*W_1 - W_2}{1 + f_3^*f_2^*f_1^*(3H + 6\pi^*L) - 2f_3^*f_2^*E_1 - 2f_3^*W_1 - W_2} c(TX_3) \cap [X_3]. \]
Then,
\[ \chi(Y) = \int_Y c(TY) \cap [Y] = \int_B \pi_* f_1^{*}f_2^{*}f_3^{*} c(TY) \cap [Y] \]
The final formula for the Euler characteristic follows directly from the pushforward theorems 2.2 and 2.3. \( \square \)
By direct expansion and specialization, we have the following three lemmas:

**Lemma 2.6.** For an elliptic threefold, the Euler characteristic of of an SU(2)\times G_2-model obtained by a crepant resolution of a Weierstrass model given in section 2.2 is:

\[
\chi(Y_3) = -6(-2c_1 \cdot L + 12L^2 + S^2 - 5S \cdot L + 2S \cdot T - 8L \cdot T + 2T^2).
\]

By applying \(c_1 = L = -K\), we have the following Lemma.

**Lemma 2.7.** In the case of a Calabi-Yau threefold, The Euler characteristic of an SU(2)\times G_2-model obtained by a crepant resolution of a Weierstrass model given in section 2.2 is:

\[
\chi(Y_3) = -6(10K^2 + S^2 + 5S \cdot K + 2S \cdot T + 8K \cdot T + 2T^2).
\]

**Lemma 2.8.** The Euler characteristic for an elliptic fourfold, the Euler characteristic of an SU(2)\times G_2-model obtained by a crepant resolution of a Weierstrass model given in section 2.2 is given by

\[
\chi(Y_4) = -6(-2c_2 \cdot L - 72L^3 + 12c_1 \cdot L^2 + c_1 \cdot S^2 - 5c_1 \cdot S \cdot L^2 c_1 \cdot S \cdot T
\]
\[
-8c_1 \cdot L \cdot T + 2c_1 \cdot T^2 + S^3 - 5S^2 \cdot L + 6S^2 \cdot T + 54S \cdot L^2
\]
\[
-44S \cdot L \cdot T + 9S \cdot T^2 + 84L^2 \cdot T - 34L \cdot T^2 + 4T^3).
\]

Again, by the Calabi-Yau condition \(c_1 = L = -K\), we have the following Lemma.

**Lemma 2.9.** In the case of a Calabi-Yau fourfold, the Euler characteristic of an SU(2)\times G_2-model obtained by a crepant resolution of a Weierstrass model given in section 2.2 is:

\[
\chi(Y_4) = -6(2c_2K + 60K^3 + S^3 + 14S^2K + 6S^2T + 49SK^2
\]
\[
+ 42SKT + 9ST^2 + 76K^2T + 32KT^2 + 4T^3).
\]

**Theorem 2.10.** In the Calabi-Yau case, the Hodge numbers of an SU(2)\times G_2-model obtained by the crepant resolution of a Weierstrass model given in section 2.2 are

\[
h^{1,1}(Y) = 14 - K^2, \quad h^{2,1}(Y) = 29K^2 + 15KS + 24KT + 3S^2 + 6ST + 6T^2 + 14.
\]

There are three fibral divisors not touching the section of the elliptic fibration. This number is exactly the rank of SU(2)\times G_2. Hence, using the Shioda-Tate-Wazir theorem, we have

\[
h^{1,1}(Y) = 10 + 1 + 3 - K^2, \quad h^{2,1}(Y) = h^{1,1}(Y) - \frac{1}{2} \chi(Y).
\]

**Theorem 2.11** (Shioda-Tate-Wazir; see corollary 4.1. of [74]). Let \(\varphi : Y \to B\) be a smooth elliptic threefold. Then,

\[
\rho(Y) = c(f) + f + \text{rank}(\text{MW}(\varphi)) + 1,
\]

where \(f\) is the number of geometrically irreducible fibral divisors not touching the zero section.

**Theorem 2.12.** Let \(Y\) be a smooth Calabi-Yau threefold elliptically fibered over a smooth variety \(B\). Assuming the Mordell-Weil group of \(Y\) has rank zero, then

\[
h^{1,1}(Y) = h^{1,1}(B) + f + 1, \quad h^{2,1}(Y) = h^{1,1}(Y) - \frac{1}{2} \chi(Y),
\]

where \(f\) is the number of geometrically irreducible fibral divisors not touching the zero section. In particular, if \(Y\) is a G-model with \(G\) a simple group, \(f\) is the rank of \(G\).
2.5 Triple intersection numbers

Let \( f : Y \to Y_0 \) be one of the crepant resolutions of a Weierstrass model given in section 2.2. Assuming that \( Y \) is a threefold, we collect the triple intersection numbers \((D_0 \cdot D_0 \cdot D_0) \cap [Y]\) of the fibral divisors as the coefficient of a cubic polynomial in \( \psi_0, \psi_1, \phi_0, \phi_1, \) and \( \phi_2 \) that couples respectively with the fibral divisors \( D_0^0, D_1^0, D_0^1, D_1^1, \) and \( D_2^1 \). We pushforward to the Chow ring of \( X_0 \) and then to the base \( B \). We recall that \( \pi : X_0 \to B \) is the projective bundle in which the Weierstrass model is defined. Then,

\[
\mathcal{F}_{\text{trip}} = \int_Y \left[ \left( \psi_0 D_0^0 + \psi_1 D_1^0 + \phi_0 D_0^1 + \phi_1 D_1^1 + \phi_2 D_2^1 \right)^3 \right] \]

Once the classes of the fibral divisors are determined, we compute the pushforward of the triple intersection numbers using theorem 2.2 successively for each blowups \( X_{i+1} \to X_i \) \((i = 2, 1, 0)\). We are then in the Chow ring of \( X_0 \) and we use theorem 2.3 to push forward to the Chow ring of \( B \) using the projective bundle map \( \pi : X_0 \to B \). We can then take the degree to end up with a number.

**Theorem 2.13.** The triple intersection polynomial of an \( SU(2) \times G_2 \)-model depends on the choice of a crepant resolution (they are listed in section 2.2) and are as follows:

**Resolution I:**

\[
\mathcal{F}_{\text{trip}}^{(I)} = -9T \phi_1 \phi_2 (\phi_2(-6L + S + 3T) - 2S \psi_1) + 3T \phi_1^3 (\phi_2(-9L + S + 6T) - 2S \psi_1) \\
- 2T \phi_2^2 (9L - 2S - 3T) + S (\psi_0 - \psi_1)^2 \\
\times (2\psi_0 (S - L) + \psi_1 (2L + S) + 9ST \psi_1 \phi_0^2) \\
+ 3T \phi_0 \left( \phi_1^3 (L - S) + 2S \phi_1 (\psi_1 + \phi_2) - 2S \left( (\psi_0 - \psi_1)^2 + \phi_2^2 \right) \right) \\
+ 2T \phi_0^3 (2L - S - 2T) + 3T \phi_0^3 (\phi_1 (-2L + S + T) - 2S \psi_1),
\]

**Resolution II:**

\[
\mathcal{F}_{\text{trip}}^{(II)} = S \psi_1^3 (-4L - 2S + T) + T \phi_2^3 (-36L + 7S + 12T) + 4T \phi_1^3 (L - T) \\
- 15ST \psi_1 \phi_2 - 3ST \psi_1 \phi_2 + 3T (-9L + S + 6T) \phi_2^2 - 6ST \phi_1^2 \psi_1 \\
+ 9T \phi_1 \phi_2 (2S \psi_1 - (6L + S + 3T) \phi_2) - T \phi_0^3 (-4L + S + 4T) \\
+ 3T \phi_0^3 (\phi_1 (-2L + S + T) - S (\psi_0 + \psi_1 + \phi_2)) \\
- 3T \phi_0 \left( \phi_1^3 (S - L) - 2S \phi_1 (\psi_1 + \phi_2) + S (\psi_0 + \psi_1 + \phi_2)^2 \right) \\
+ 6ST \psi_0 \phi_1 \phi_2 - 3ST \psi_0 \phi_2^2 - 3ST \psi_0^2 \phi_2 + 3S \psi_1 \phi_0^3 (-4L + 2S + T) \\
+ 3S \psi_1^2 \psi_0 (4L - T) - S \psi_0^3 (-4L + 4S + T),
\]
Resolution III:

\[ F_{\text{trip}}^{(\text{III})} = -3T(9L - 2(S + 3T))\phi_1^2\phi_2 - 3T\phi_1\phi_2^2(-18L + 4S + 9T) - 3ST\psi_1\phi_1^2 \\
- 12ST\psi_1\phi_2^2 + T\phi_1^2(4L - S - 4T) - 4ST\phi_0^2(9L - 2S - 3T) - 3ST\psi_1^2\phi_1 \\
+ 12ST\psi_1\phi_1\phi_2 - 2S(2L + S - T)\psi_1^2 + 3T\phi_0^2(\phi_1(T - 2L) - 2ST) \\
+ 3T\phi_0\phi_1(L\phi_1 + 2S\psi_0) - 3ST\psi_0\phi_2^2 + 6ST\psi_0\phi_1\phi_2 + 6ST\psi_0\psi_1\phi_1 \\
- 3ST\psi_0\phi_1 - 2S(-2L + 2S + T)\psi_0(\psi_0^2 - 2\psi_0\phi_1 + \psi_1^2) \\
- 2S(2L + S - T)\psi_0(\psi_0\psi_1 - 2\psi_1^2) - 6ST\psi_0\phi_2^2 + 4T\phi_0^2(L - T), \]

Resolution IV:

\[ F_{\text{trip}}^{(\text{IV})} = S(-4L - 2S + 3T)\psi_1^3 + 4T(L - T)\phi_1^3 + 9T(2T - 3L)\phi_1^2\phi_2 \\
+ 27T(2L - T)\phi_1\phi_2^2 + 12T(T - 3L)\phi_2^3 - 6ST\psi_1^2\phi_2 \\
+ S\phi_0^3(4L - 4S - 3T) + 4T\phi_0^2(L - T) + \phi_0^3(3T\phi_1(T - 2L) - 6ST\psi_0) \\
+ \psi_0^2(3S(-4L + 2S + 3T)\psi_1 - 6ST\phi_2) + 3T\phi_0\phi_1(L\phi_1 + 2S\psi_0) \\
+ 3S\psi_0(\psi_1^2(4L - 3T) + 4T\psi_1\phi_2 - 2\phi_1^2 + 6T\phi_1\phi_2 - 6T\phi_1^2). \]

**Proof.** We give the proof for the case of resolution I discussed in detail in section 3.1; the other cases follow the same pattern.

\[
F_{\text{trip}} = \int_{X_3} \left( \left( \psi_0^2 + \psi_1^2 + \phi_0^2 + \phi_1^2 + \phi_2^2 \right)^3 \right) \\
= \int_{X_3} \left[ \left( \psi_0^2 + \psi_1^2 + \phi_0^2 + \phi_1^2 + \phi_2^2 \right)^3 \left( 3H + 6L - 2E_1 - 2W_1 - W_2 \right) \right] \\
= \int_{X_0} f_1*f_2*f_3* \left[ \left( \psi_0^2 + \psi_1^2 + \phi_0^2 + \phi_1^2 + \phi_2^2 \right)^3 \right] \\
\times \left( 3H + 6L - 2E_1 - 2W_1 - W_2 \right) \\
= \int_{B} \pi_1*f_1*f_2*f_3* \left[ \left( \psi_0^2 + \psi_1^2 + \phi_0^2 + \phi_1^2 + \phi_2^2 \right)^3 \right] \\
\times \left( 3H + 6L - 2E_1 - 2W_1 - W_2 \right).
\]

The classes of the fibral divisors in the Chow ring of \(X_3\) are

\[
[D_0] = S - E_1, \quad [D_1] = E_1, \quad [D_0'] = T - W_1, \quad [D_1'] = W_1 - W_2, \quad [D_2'] = 2W_2 - W_1.
\]

Denoting by \(M\) an arbitrary divisor in the class of the Chow ring of the base, The nonzero product intersection numbers of \(M, H, E_1, W_1,\) and \(W_2\) are

\[
\int_Y H^3 = 27L^2, \quad \int_Y E_1^3 = -2S(2L + S), \\
\int_Y W_1^3 = -2T(2L - S + T), \quad \int_Y W_2^3 = -T(5L - 2S + T), \\
\int_Y W_1^2E_1 = -2ST, \quad \int_Y W_1^2W_2 = T(2L + S - T).
\]
\[
\int_Y W_2^2 E_1 = -2ST, \quad \int_Y W_2^2 W_1 = T(-L + S - 2T),
\]
\[
\int_Y H^2 M = -9LM, \quad \int_Y H M^2 = 3M^2, \quad \int_Y E_1 W_1 W_2 = -ST,
\]
\[
\int_Y M H^2 = -9LM, \quad \int_Y M E_1^2 = -2SM,
\]
\[
\int_Y M W_1^2 = -2TM, \quad \int_Y M W_2^2 = -2TM.
\]

The triple intersection numbers of the fibral divisors follow from these by simple linearity.

\[\square\]

The triple intersection polynomials computed in theorem 2.13 are very different from each other in chambers I, II, III, and IV.

2.6 Hyperplane arrangement

We consider the semi-simple Lie algebra
\[
\mathfrak{g} = A_1 \oplus g_2.
\]

An irreducible representation of \(A_1 \oplus g_2\) is always a tensor product \(R_1 \otimes R_2\), where \(R_1\) and \(R_2\) are respectively irreducible representations of \(A_1\) and \(g_2\). Following a common convention in physics, we denote a representation by its dimension in bold character. The weights are denoted by \(\varpi^I_j\) where the upper index \(I\) denotes the representation \(R_I\) and the lower index \(j\) denotes a particular weight of the representation \(R_I\). A weight of a representation of \(A_1 \oplus g_2\) is denoted by a triple \((a; b; c)\) such that \((a)\) is a weight of \(A_1\) and \((b, c)\) is a weight of \(g_2\), all in the basis of fundamental weights. A vector \(\phi\) of the coroot space of \(A_1 \oplus g_2\) is written as \(\phi = (\psi_1; \phi_1, \phi_2)\), where \(\psi_1\) is the projection of \(\phi\) on the fundamental coroot of \(A_1\) and \((\phi_1, \phi_2)\) are the coordinates of the projection of \(\phi\) along the coroot of \(G_2\) expressed in the basis of fundamental coroots. Each weight \(\varpi\) defines a linear form by the natural evaluation on coroot vectors. We recall that fundamental coroots are dual to fundamental weights.

We attach to an SU(2) \(\times G_2\)-model the representation
\[
R = (3, 1) \oplus (1, 14) \oplus (2, 7) \oplus (2, 1) \oplus (1, 7). \tag{2.4}
\]

The weights \(\varpi^I_j\) of each summand are listed in table 2.

We would like to study the arrangement of hyperplanes perpendicular to the weights of the representation \(R\) inside the dual fundamental Weyl chamber of \(A_1 \oplus g_2\). The only representation that will contribute to the interior walls is the bifundamental \((2, 7)\).

**Theorem 2.14.** The hyperplane arrangement \(I(A_1 \oplus g_2, R)\) with \(R = (2, 7)\) has four chambers whose sign vectors and whose adjacency graph is given in figure 1. A choice of a sign vector is \(\varpi_5^{(2, 7)}, \varpi_6^{(2, 7)}, \varpi_7^{(2, 7)}\). With respect to it, the chambers are listed in table 3.
In this section, we study the fibral structure of the elliptic fibrations obtained by the crepant collapsing curves in table 4. These are curves whose weights differ only by a sign.

### 2.7 Flops

First we consider when 

$$\psi_1 > 0, \quad 2\phi_1 - \phi_2 > 0, \quad -3\phi_1 + 2\phi_2 > 0. \quad (2.5)$$

There are only three hyperplanes intersecting the interior of the fundamental Weyl chamber:

$$\varpi^{(2,7)}_5, \varpi^{(2,7)}_6, \varpi^{(2,7)}_7.$$

We use them in the order \((\varpi^{(2,7)}_5, \varpi^{(2,7)}_6, \varpi^{(2,7)}_7)\), the sign vector is

$$(\psi_1 - 2\phi_1 - \phi_2, \psi_1 + \phi_1 - \phi_2, \psi_1 - \phi_2).$$

First we consider when \(\psi_1 - \phi_1 > 0\). Then \(\varpi^{(2,7)}_5 = \psi_1 - \phi_1 > 0\), \(\varpi^{(2,7)}_6 = \psi_1 + \phi_1 - \psi_1 + \phi_1 - \phi_2 = (\psi_1 - \phi_1) + (2\phi_1 - \phi_2) > 0\), and \(\varpi^{(2,7)}_7 = \psi_1 - 2\phi_1 + \phi_2 = (\psi_1 - \phi_1) + (2\phi_1 - \phi_2) + (-3\phi_1 + 2\phi_2) = \varpi^{(2,7)}_6 + (-3\phi_1 + 2\phi_2) > 0.\)

When \(\psi_1 - \phi_1 < 0\), \(\varpi^{(2,7)}_5 = \psi_1 - \phi_1 < 0\). Then we have either \(\varpi^{(2,7)}_6 = \psi_1 + \phi_1 - \phi_2 = (\psi_1 - \phi_1) + (2\phi_1 - \phi_2) > 0\), or \(\varpi^{(2,7)}_6 = \psi_1 + \phi_1 - \phi_2 = (\psi_1 - \phi_1) + (2\phi_1 - \phi_2) < 0\). If \(\varpi^{(2,7)}_6 > 0\), it follows that \(\varpi^{(2,7)}_7 = \varpi^{(2,7)}_6 + (-3\phi_1 + 2\phi_2) > 0\). When \(\varpi^{(2,7)}_6 = \psi_1 + \phi_1 - \phi_2 = (\psi_1 - \phi_1) + (2\phi_1 - \phi_2) < 0\), we can have both \(\varpi^{(2,7)}_7 > 0\) and \(\varpi^{(2,7)}_7 < 0\). See table 3. \(\square\)

### 2.7 Flops

In this section, we discuss the flops between the resolutions I, II, III, IV. We identify the flopping curves in table 4. These are curves whose weights differ only by a sign.

## 3 The crepant resolutions and fiber structures

In this section, we study the fibral structure of the elliptic fibrations obtained by the crepant resolutions of the SU(2) \(\times G_2\)-model given by the Weierstrass model

$$Y_0: \quad y^2 = x^3 + f st^2 x + gs^2 t^3.$$ (3.1)
The proper transform of the Weierstrass model is
\[ Y : w_2 y^2 = w_1 (e_1 x^3 + f s t^2 x + g s^2 t^3). \] (3.3)

The projective coordinates are then given by
\[ [e_1 w_1 w_2 x ; e_1 w_1 w_2^2 y ; z = 1] w_1 w_2 x ; w_1 w_2 y ; s][x ; w_2 y ; t][y ; w_1]. \] (3.4)

The fibral divisors are given by \( se_1 = 0 \) for type III and \( tw_1 w_2 = 0 \) for type I:\textsuperscript{ns}:
\[
\begin{align*}
\text{III} & \quad : \\
D_0^3 & \quad : s = w_2 y^2 - w_1 e_1 x^3 = 0, \\
D_1^3 & \quad : e_1 = w_2 y^2 - s t^2 w_1 (f x + g s t) = 0. \\
\text{I:\textsuperscript{ns}} & \quad : \\
2D_1^3 & \quad : t = w_2 y^2 - w_1 e_1 x^3 = 0, \\
D_2^3 & \quad : w_1 = w_2 = 0, \\
D_3^3 & \quad : w_2 = e_1 x^3 + f s t^2 x + g s^2 t^3 = 0.
\end{align*}
\] (3.5)
Figure 4. Codimension-two Collision of SU(2) \times G_2-model at S \cap T, Resolution I. This fiber is of type III* (with dual graph E_7) with contracted nodes.

\[
\begin{array}{c}
\eta_0^0 \\
\eta_1^0 \quad 2 \\
\eta_2^0 \\
3 \\
\eta_1^{12} \\
\eta_1^2 \\
2 \\
\eta_0^2
\end{array}
\]

On the intersection of S and T, we see the following curves:

\[
\begin{align*}
\text{On } S \cap T : \\
D_0 \cap D_0' &\to \eta_0^0 : s = t = w_2y^2 - w_1x_1x^3 = 0, \\
D_1 \cap D_0' &\to \eta_1^{02} : e_1 = t = w_2 = 0, \quad \eta_1^{0A} : e_1 = t = y = 0, \\
D_1' \cap D_1' &\to \eta_1^{12} : e_1 = w_1 = w_2 = 0, \\
D_1' \cap D_1 &\to \eta_1^{02} : e_1 = w_1 = w_2 = t = 0, \quad \eta_2^2 : e_1 = w_2 = fx + gst = 0.
\end{align*}
\]

(3.6)

Hence we can deduce that the five fibral divisors split in the following way to produce the fiber in figure 4, which is a fiber of type IV* with contracted nodes.

\[
\begin{align*}
\text{On } S \cap T : \\
C_6 &\longrightarrow \eta_0^0, \\
C_1 &\longrightarrow 2\eta_1^{0A} + 3\eta_1^{02} + 2\eta_1^{12} + \eta_1^2, \\
C_0 &\longrightarrow \eta_0^0 + \eta_1^{02} + 2\eta_1^{0A}, \\
C_1 &\longrightarrow \eta_1^{12}, \\
C_2 &\longrightarrow 2\eta_1^{02} + \eta_1^2.
\end{align*}
\]

(3.7)

In order to get the weights of the curves, the intersection numbers are computed between the codimension-two curves and the fibral divisors.

The fiber of figure 4 specializes further when f = 0:

\[
\eta_1^2 \longrightarrow \eta_1^{02}.
\]

(3.8)

This corresponds to the non-Kodaira diagram in figure 5, which is a fiber of type II* with contracted nodes.
Figure 5. Codimension-three enhancement of SU(2) x G2-model at S ∩ T ∩ V(f), Resolution I. This fiber is of type II* (with dual graph Ė₀) with contracted nodes.

3.2 Resolution II

In this section, we study Resolution II in detail. Resolution II requires a first blowup that does not have a smooth center; it is useful to rewrite equation (2.1) as

\[ Y_0 : \begin{cases} y^2 = x^3 + fp_0 tx + gp_0^2 t, \\ p_0 = st. \end{cases} \]  

Resolution II is given by the following sequence of blowups

\[ X_0 \xleftarrow{(x,y,p_0|p_1)} X_1 \xleftarrow{(y,t,p_1|w_1)} X_2 \xleftarrow{(t,p_0|w_2)} X_3, \]  

where \( X_0 = \mathbb{P}[\mathcal{O}_B \oplus \mathcal{O}^2 \oplus \mathcal{O}^3] \). The projective coordinates are then

\[ [p_1 w_1 x : p_1 w_1^2 y : z = 1][x : w_1 y : p_0 w_2][y : tw_2 : p_1][t : p_0], \]  

and the proper transform is

\[ Y : \begin{cases} w_1 y^2 = p_1 x^3 + fp_0 tp^2 x + gp_0^2 tw^3, \\ p_0 p_1 = st. \end{cases} \]

\[ X_1 = Bl_{(x,y,p_0)} X_0 \] has double point singularities at the ideal \((p_0, p_1, s, t)\). Recall that we have two curves from III and three curves from I₀ individually. We denote by \( D^s_0 \) and \( D^t_0 \) the fibral divisors that project to \( S \) and \( T \):

\[ \text{III} : \begin{cases} D^s_0 : s = p_0 = w_1 y^2 - p_1 x^3 = 0 \\ D^s_1 : s = p_1 = w_1 y^2 - (p_1 x^3 + p_0 tw_2^3)(fx + gp_0 w_2) = 0 \\ D^t_0 : w_2 = p_0 p_1 - st = w_1 y^2 - p_1 x^3 = 0 \\ D^t_1 : t = p_1 = w_1 = 0 \\ D^t_2 : w_1 = p_0 p_1 - st = p_1 x^3 + p_0 tw_2^3(fx + gp_0 w_2) = 0 \end{cases} \]  

(3.13)

At the intersection of \( S \) and \( T \), the fiber enhances to a non-Kodaira fiber presented in figure 6, which is a fiber of type III* with contracted nodes. This is realized by the following splitting of curves.

\[ \begin{align*}
C^s_0 & \rightarrow n^0_0 + n^0_1 \\
C^s_1 & \rightarrow n^0_1 + 3n^{12}_1 + 2n^{02}_1 + n^2_1 \\
C^t_0 & \rightarrow n^0_0 + n^{02}_1 \\
C^t_1 & \rightarrow n^{12}_1 \\
C^t_2 & \rightarrow 2n_{01} + 2n^{12}_{01} + n^2_1 + \eta^2_1
\end{align*} \]

On \( S \cap T \):

\[ \begin{align*}
\begin{cases} C^s_0 & \rightarrow n^0_0 + n^0_1 \\
C^s_1 & \rightarrow n^0_1 + 3n^{12}_1 + 2n^{02}_1 + n^2_1 \\
C^t_0 & \rightarrow n^0_0 + n^{02}_1 \\
C^t_1 & \rightarrow n^{12}_1 \\
C^t_2 & \rightarrow 2n_{01} + 2n^{12}_{01} + n^2_1 + \eta^2_1 \end{cases} \]  

(3.14)
Figure 6. Codimension-two Collision of SU(2)×G₂-model at S∩T, Resolution II. This fiber is of type III* (with dual graph E₇) with contracted nodes.

|       | D₀ | D₁ | D₂ | Weight             | Representation |
|-------|----|----|----|--------------------|----------------|
| η₀₀  | -1 |  1 |  0 | [-1;1,0]           | (2,7)          |
| η₀₁  | -1 |  1 |  1 | [-1;1,0]           | (2,7)          |
| η₁₀  |  1 | -1 | -1 | [1;1,1]            | (2,7)          |
| η₁₁  |  0 |  0 | -2 | [0;3,2]            | (1,14)         |
| η₂₀  |  0 |  0 |  1 | [0;2,-1]           | (1,7) ⊂ (1,14) |

Table 6. Weights and representations of the components of the generic curve over S∩T in Resolution II of the SU(2)×G₂-model. See section 4.2 for more information on the interpretation of these representations.

The curves at the intersection are given by

\[
\begin{align*}
D₀ \cap D₁ &\rightarrow \eta₀₀ : s = p₀ = w₂ = w₁y² - p₁x³ = 0, \\
D₀ \cap D₂ &\rightarrow \eta₀₁ : s = p₀ = w₁ = p₁ = 0, \\
D₁ \cap D₀ &\rightarrow \eta₁₀ : s = p₁ = w₂ = w₁ = 0, \\
D₁ \cap D₁ &\rightarrow \eta₁₁ : s = p₁ = t = w₁ = 0, \\
D₁ \cap D₂ &\rightarrow \eta₁₂ : s = p₁ = w₁ = f x + g p₀ w₂ = 0, \\
\eta₀₁ : s = p₁ = w₁ = p₀ = 0, \\
\eta₁₁ : s = p₁ = w₁ = t = 0, \\
\eta₀₂ : s = p₁ = w₁ = w₂ = 0.
\end{align*}
\]

(3.15)

The fiber enhances further over f = 0:

\[
\eta₁ \longrightarrow \eta₀₁ + \eta₀₂.
\]

(3.16)

For this codimension-three enhancement, we get a non-Kodaira fiber corresponding to figure 7, which is a fiber of type II* with contracted nodes.

3.3 Resolution III

Consider the following sequence of blowups:

\[
X₀ \xleftarrow{(x, y, t|w₁)} X₁ \xleftarrow{(x, y, s|e₁)} X₂ \xleftarrow{(y, w₁|w₂)} X₃.
\]

(3.17)
Figure 7. Codimension-three enhancement of SU(2) × G2-model at $S \cap T \cap V(f)$, Resolution II. This fiber is of type II* (with dual graph $\tilde{E}_6$) with contracted nodes.

Figure 8. Codimension-two Collision of SU(2) × G2-model at $S \cap T$, Resolution III. This fiber is of type III* (with dual graph $\tilde{E}_7$) with contracted nodes.

The projective coordinates are then given by

$$[e_1 w_1 w_2 x; e_1 w_1 w_2^2 y; z = 1][e_1 x; e_1 w_2 y; t][x; w_2 y; s][y; w_1]. \quad (3.18)$$

The proper transform is identical to equation (3.3). It follows that the fibral divisors are also identical to equation (3.5).

On the intersection of $S$ and $T$, we see the following curves:

$$\begin{align*}
D_0^1 & \cap D_1^2 \to \eta_{01}^0 : s = w_2 = e_1 = 0, \\
D_0^1 & \cap D_1^2 \to \eta_{12}^0 : s = w_1 = w_2 = 0,
\end{align*}$$

$$\begin{align*}
D_0^1 & \cap D_1^2 \to \eta_{01}^0 : s = w_2 = e_1 = 0, \\
D_1^2 & \cap D_0^1 \to \eta_{12}^1 : e_1 = w_1 = w_2 = 0,
\end{align*}$$

$$\begin{align*}
D_1^2 & \cap D_0^1 \to \eta_{12}^1 : e_1 = w_2 = fx +gst = 0, \\
D_1^2 & \cap D_2^1 \to \eta_{12}^2 : e_1 = w_2 = fx +gst = 0.
\end{align*}$$

The resulting fiber is a non-Kodaira fiber illustrated in figure 8 and corresponding to a fiber of type III* with three contracted nodes.

$$\begin{align*}
C_0^0 & \to \eta_{01}^0 + 2\eta_{01}^{12} + 2\eta_{01}^2, \\
C_0^1 & \to \eta_{01}^0 + 2\eta_{01}^{12} + 2\eta_{12}^1,
\end{align*}$$

$$\begin{align*}
C_0^1 & \to \eta_{01}^0 + 2\eta_{01}^{12} + 2\eta_{12}^1, \\
C_2^1 & \to 2\eta_{01}^0 + \eta_{12}^1.
\end{align*}$$

In order to get the weights of the curves, the intersection numbers are computed between the codimension-two curves and the fibral divisors.
Table 7. Weights and representations of the components of the generic curve over $S \cap T$ in Resolution III of the SU(2) $\times G_2$-model. See section 4.2 for more information on the interpretation of these representations.

| $\eta^0_0$ | $\eta^0_1$ | $\eta^0_2$ | $\eta^0_3$ | $\eta^0_4$ | Weight | Representation |
|------------|------------|------------|------------|------------|---------|----------------|
| 0          | 0          | -2         | 1          | 0          | [0;0,−1] | (1, 7) ⊂ (1, 14) |
| -1         | 1          | 1          | -1         | 1          | [-1;−1,1] | (2, 7) |
| 1          | -1         | 0          | -1         | 2          | [1;−2,1]  | (2, 7) |
| 0          | 0          | 0          | 1          | -2         | [0;2,−1]  | (1, 7) ⊂ (1, 14) |
| 0          | 0          | 0          | 1          | -2         | [0;2,−1]  | (1, 7) ⊂ (1, 14) |

![Diagram](image)

Figure 9. Codimension-three enhancement of SU(2) $\times G_2$-model at $S \cap T \cap V(f)$, Resolution III. This fiber is of type II* (with dual graph $E_8$) with contracted nodes.

We have a further enhancement when $f = 0$ as the rational curve $\eta^2_1$ coincides with $\eta^0_0$:

$$
\eta^2_1 \rightarrow \eta^0_0.
$$

(3.21)

This corresponds to the codimension-three enhancement in figure 9, which is a fiber of type III$^*$ with contracted nodes.

3.4 Resolution IV

The last crepant resolution of the SU(2) $\times G_2$-model is given by the following sequence of blowups:

$$
X_0 \xrightarrow{(x, y, t|w_1)} X_1 \xleftarrow{(y, w_1|w_2)} X_2 \xrightarrow{(x, y, s|e_1)} X_3.
$$

(3.22)

Its projective coordinates are then given by

$$
[e_1 w_1 w_2 x; e_1 w_1 w_2 y; z = 1][e_1 x; e_1 w_2 y; t][e_1 y; w_1][x; y; s].
$$

(3.23)

The proper transform is identical to equation (3.3). It follows that the divisors are also identical to equation (3.5). On the intersection of $S$ and $T$, we see the following curves:

$\begin{align*}
D^s_0 \cap D^s_1 & \rightarrow \eta^0_0 : s = t = w_2 y^2 - w_1 e_1 x^3 = 0, \\
D^s_0 \cap D^s_1 & \rightarrow \eta^0_1 : s = w_1 = w_2 = 0,
\end{align*}$

On $S \cap T$:

$\begin{align*}
D^s_0 \cap D^s_2 & \rightarrow \eta^0_2 : s = w_2 = x = 0, & \eta^0_1 : s = w_2 = e_1 = 0, \\
\eta^0_1 & : s = w_2 = w_1 = 0, \\
D^s_1 \cap D^s_2 & \rightarrow \eta^0_1 : e_1 = w_2 = fx + gyt = 0, & \eta^0_0 : e_1 = w_2 = s = 0.
\end{align*}$

(3.24)
Figure 10. Codimension-two Collision of SU(2) × G2-model at S ∩ T, Resolution IV. This fiber is of type III* (with dual graph E7) with contracted nodes.

|          | $D_0^1$ | $D_1^1$ | $D_2^1$ | Weight   | Representation |
|----------|---------|---------|---------|----------|----------------|
| $\eta_0^0$ | 0       | 0       | −2      | 1        | [0;0,−1]       |
| $\eta_1^{12}$ | 0       | 0       | 1       | −2       | [0;−3,2]       |
| $\eta_2^{2B}$ | −1      | 1       | 0       | 1        | [−1;2,−1]      |
| $\eta_0^1$ | 1       | −1      | 0       | 0        | [1;0,0]        |
| $\eta_2^1$  | 1       | −1      | 0       | 0        | [1;0,0]        |

Table 8. Weights and representations of the components of the generic curve over $S ∩ T$ in Resolution IV of the SU(2) × G2-model. See section 4.2 for more information on the interpretation of these representations.

Figure 11. Codimension-three enhancement of SU(2) × G2-model at $S ∩ T ∩ V(f)$, Resolution IV. This fiber is of type II* (with dual graph E8) with contracted nodes.

Hence, we can deduce that the five fibral divisors split in the following way to produce the fiber in figure 10, which is a fiber of type III* with contracted nodes.

\[
\begin{align*}
C_0^0 & \rightarrow \eta_0^0 + 2\eta_1^{12} + 3\eta_2^{2B} + \eta_0^1, \\
C_1^0 & \rightarrow \eta_0^1 + \eta_1^1, \\
C_0^1 & \rightarrow \eta_0^1, \\
C_1^1 & \rightarrow \eta_0^{12}, \\
C_2^1 & \rightarrow 3\eta_2^{2B} + 2\eta_0^1 + \eta_1^2.
\end{align*}
\]

On $S ∩ T$:

\[
\begin{align*}
C_0^0 & \rightarrow \eta_0^0 + 2\eta_1^{12} + 3\eta_2^{2B} + \eta_0^1, \\
C_1^0 & \rightarrow \eta_0^1 + \eta_1^1, \\
C_0^1 & \rightarrow \eta_0^1, \\
C_1^1 & \rightarrow \eta_0^{12}, \\
C_2^1 & \rightarrow 3\eta_2^{2B} + 2\eta_0^1 + \eta_1^2.
\end{align*}
\]

In order to get the weights of the curves, the intersection numbers are computed between the codimension-two curves and the fibral divisors.

For the codimension-three fiber enhancement, consider when $f = 0$. Note that only the fiber $\eta_1^2$ changes under this condition:

\[
\eta_1^2 \rightarrow \eta_0^2.
\]

Even though only a single curve changed, we get a completely different fiber as a result. The codimension-three enhancement is represented in figure 11, which is a fiber of type III* with contracted nodes.
3.5 Fiber structure

In this section, we describe codimension-one and codimension-two fiber enhancements of all the resolutions (Resolutions I, II, III, IV) of the SU(2) \times G_2-model. We consider two different ways of realizing the SU(2) \times G_2-model: the collision of the fibers of type III+I_0^{S_3} and III + I_0^{Z_3} depending on the Galois group of the fiber I_0^{ns}. The Weierstrass equation of type III+I_0^{S_3} is given by $y^2 = x^3 + f s t^2 x + g s^2 t^3$, whereas that of type III + I_0^{Z_3} is given by $y^2 = x^3 + f s t^{3+\alpha} x + g s^2 t^3$. Resolutions I, II, III, and IV of the collision of the type III+I_0^{S_3} are represented in figures 12, 13, 14, and 15 respectively. Resolutions I, II, III, and IV of the collision of type III + I_0^{Z_3} are represented in figure 16.

Figure 12. III + I_0^{S_3}, Resolution I.
Figure 13. III + $I_0^{S_3}$, Resolution II.

Figure 14. III + $I_0^{S_3}$, Resolution III.
Figure 15. III $+$ $I_0^{S_3}$, Resolution IV.
Figure 16. III + $I_0^{Z_2}$, $y^2 = x^3 + f s t^5 + \alpha x + g s^2 t^3$. Resolution I, II, III, and IV. The fibers in codimension-two are arranged in the order of the resolution. There are no more enhancements in higher codimension.
4 Deriving the matter representation of an SU(2) × G2-model

In this section, we explain how to derive the representation attached to an SU(2) × G2-model. We first explain how the Katz-Vafa method does not give the correct representation for the SU(2) × G2-model. We use instead the notion of saturation of weights starting with a set of weights derived geometrically by intersecting the fibral divisors by the irreducible components of singular fibers over codimension-two points.

4.1 Failing of the Katz-Vafa method for the SU(2) × G2-model

The Katz-Vafa method was defined for rank-one enhancements between Lie algebras of type ADE [56]. For a G-model with a simple Lie group G, the Katz-Vafa method provides an elegant derivation of the matter content. This method had enabled the F-theory constructions to be independent from the existence of a Heterotic dual to explain their matter content. In collision of singularities, given two simple groups G1 and G2, we can determine the group G that corresponds to their collision by considering an elliptic surface whose discriminant locus pass by one of the points of intersection of the divisors supporting G1 and G2.

The Katz-Vafa method uses as input a triple (G1, G2, G) of Lie groups such that G1 ⊗ G2 ⊂ G and returns representations R_i appearing in the branching rule for the decomposition of the adjoint of g = Lie(G) in terms of representations of G1 × G2.

\[ g = g_1 ⊕ g_2 ⊕ R_1 ⊕ ⋯ ⊕ R_n, \]

where R_i are representations of G1 × G2.

The branching rules for G ⊃ G1 ⊗ G2 provide the Katz-Vafa representations R_i = (r_i^{(1)}, r_i^{(2)}) for the collision of G1 and G2:

\[ \text{adj}(g) = \text{adj}(g_1) ⊕ \text{adj}(g_2) ⊕ \bigoplus_i (r_i^{(1)}, r_i^{(2)}). \tag{4.1} \]

The original motivation for Katz-Vafa was to give an intrinsic derivation of the matter content of F-theory without relying on the duality with the Heterotic string theory. In six-dimensional theories, anomaly cancellations are a sanity check for the identification of the correct representations. But a direct derivation is still necessary as anomalies do not uniquely identify the matter content. In explicit examples, we often have a rank-one enhancement with G1 × U(1) ⊂ G with G1 given via the fiber structure and G to be determined.

The Katz-Vafa method does not always produce the correct matter content, in particular, the matter content of the SU(2) × G2-model cannot be derived by the Katz-Vafa method. The geometry of the fibration shows that at the collision of S and T, the fibers are contractions of fibers of type III’ whose dual graph is the affine Dynkin diagram of type E7. The Lie algebra of SU(2) × G2 is a maximal subalgebra of type S of E7. The branching rule for the adjoint representation of E7 in terms of the representation of SU(2) × G2 is as follows [61] :

\[ 133 = (3, 1) ⊕ (1, 14) ⊕ (5, 7) ⊕ (3, 27). \tag{4.2} \]
The two summands \((3, 1)\) and \((1, 14)\) are the two components of the adjoint representation of SU(2) \(\times G_2\). Thus, the remaining parts \((5, 7) \oplus (3, 27)\) should give the matter content of the SU(2) \(\times G_2\)-model according to the Katz-Vafa method. However, the representations \((5, 7)\) and \((3, 27)\) are incompatible with the weights from the geometry after resolving the singularities of the SU(2) \(\times G_2\)-model, as they do not contain the weights of the bifundamental representation \((2, 7)\).

### 4.2 Saturation of weights and representations

To determine the representation \(R\) attached to a given elliptic fibration, over each codimension-two point, we identify a subset of weights of \(g\) using intersection theory. This process can be explained in the following steps:

1. **We first identify all the fibral divisors\(^3\) of the elliptic fibration. Each fibral divisor is a fibration over an irreducible component of the discriminant locus.**

2. **Then, we collect all the singular fibers over codimension-two points of the base where the generic fibers of the fibral divisors degenerate further. Assuming that the fibration is equidimensional up to codimension-two points, all the irreducible components of the singular fibers are necessarily rational curves that we call rational vertical curves.**

3. **We compute the intersection numbers of these rational vertical curves with the fibral divisors. In this way, we attach to each irreducible components of a singular fiber over a codimension-two point a vector with integer entries. If we consider only the fibral divisors not touching the section of the elliptic fibration, we get a vector of dimension equal to the rank of the Lie algebra \(g\); we identify the negative of such a vector with an element of the weight lattice of \(g\).**

4. **We determine the representation \(R\) attached to the weights of the rational vertical curves over each codimension-two points. The representation \(R\) has to necessarily contain all the weights that we have identified by intersections of rational vertical curves with the fibral divisors.**

In the last step, the goal is then to determine the minimal representation generated by the subset of weights given to us by the geometry. A systematic way to do so is to use the notion of saturation of weights introduced by Bourbaki (see [18, chapter VIII.\(\S\)7, Section 2]). The identification of a representation using weights obtained by intersection numbers can be traced back to Aspinwall and Gross [7]; it is based on the M-theory picture of M2-branes wrapping chains of curves and becoming massless when the curve shrinks to a point. The use of saturation of weights in this context was first explained in [33] and inspired directly by [7] and [18]. See also [60, 64].

\(^3\)Under mild assumptions, the discriminant locus of an elliptic fibration \(\varphi : Y \to B\) is a divisor \(\Delta\). The **fibral divisors** are by definition the irreducible components of the pullback \(\varphi^*(\Delta_{\text{red}})\) where \(\Delta_{\text{red}}\) is the reduced discriminant.
**Definition 4.1.** A set \( \Pi \) of integral weights is said to be *saturated* if for all \( \mu \in \Pi \), for all roots \( \alpha \), and for all \( t \) between 0 and \( \langle \mu, \alpha \rangle \), we have \( \mu - t\alpha \in \Pi \). The *saturation* of a set of weights \( \Pi \) is the smallest saturated set containing \( \Pi \).

We refer to Bourbaki [18, chapter VIII. §7. Section 2] for more information on saturated sets of weights. A direct consequence of the definition is that a saturated set of weights is invariant under the Weyl group. Given a representation \( \mathbf{R} \), its set of weights \( \Phi_\mathbf{R} \) is a saturated set of weights.

**Theorem 4.2** (See corollary of proposition 5 of [18, Chapter VIII. §7. Section 2]). For any finite saturated set of weights \( \Pi \), there exists a finite-dimensional representation \( \mathbf{R} \) such that \( \Pi \) is the set of weights of \( \mathbf{R} \).

Thus, the saturation of weights attaches a representation \( \mathbf{R} \) to a finite set of weights \( \Pi \) in a systematic way: \( \mathbf{R} \) is the unique representation whose set of weights is the saturation of \( \Pi \). In other words, \( \mathbf{R} \) is the representation generated by the set of weights \( \Pi \). There can be other representations containing the saturation of \( \Pi \) as a proper subset of their set of weights.

We determine the representation \( \mathbf{R} \) attached to an elliptic fibration by first interpreting the negative of the intersection of vertical curves (over codimension-two points) with the fibral divisors as elements of the weight lattice. We then associate a representation to these weights using the notion of saturation of weights [33, 38, 39].

We illustrate the method with Resolution I. In Resolution I, the curve \( C^s_1 \) degenerates as follows over \( S \cap T \):

\[
C^s_1 \to 3\eta_1^{02} + 2\eta_1^{04} + 2\eta_1^{12} + \eta_1^{1},
\]

where \( \eta_1^{02} \) and \( \eta_1^{1} \) have weight \( [0; 2, -1] \), which is a weight of the fundamental representation \( (1, 7) \subset (1, 14) \). \( \eta_1^{04} \) has weight \( [1; -1, 0] \) of the bifundamental representation \( (2, 7) \subset (2, 14) \), and \( \eta_1^{12} \) has weight \( [0; -3, 2] \) of the adjoint representation \( (1, 14) \).

In Resolution IV, the curve \( C^s_1 \) undergoes the following degeneration over \( S \cap T \):

\[
C^s_1 \to \eta_0^{12} + \eta_1^{1},
\]

where both \( \eta_0^{12} \) and \( \eta_1^{1} \) have weight \( [1; 0, 0] \), which is a weight of the representation \( (2, 1) \subset (2, 7) \). There is another curve \( (\eta_0^{12B}) \) coming from the degeneration of \( C^s_0 \) that carries the weight \( [-1, 2, -1] \) of the bifundamental \( (2, 7) \) of \( \text{SU}(2) \times G_2 \).

To make sense of the representation we should attach to these degenerations, we recall first few fact about the weights involved. The adjoint representation of \( G_2 \) consists of fourteen weights that split into four orbits under the action of the Weyl group: each of the two zero weights form an orbit on its own, the six short roots form an orbit, and the six long weights form the fourth orbit. The short roots of the adjoint of \( G_2 \) are the nonzero weights of the fundamental representation \( 7 \) of \( G_2 \). The highest weight of the adjoint representation is a long root; thus, the adjoint representation is the smallest representation containing the saturation set of any subset of long roots. The bifundamental representation of \( \text{SU}(2) \times G_2 \) \( (2, 7) \) consists of the following Weyl orbits: the two weights \( [\pm 1; 0, 0] \) form
an orbit corresponding to the representation $(2,1)$, and the other twelve weights form a unique orbit. Thus we can conclude the saturations from the weights are given by Table 9.

Table 9. Representations derived from saturation of weights.

| Set of weights II | Saturation of II |
|-------------------|------------------|
| $\{0;2,-1\}$      | the fundamental rep. $(1,7)$ |
| $\{1;-1,0\}$      | the bifundamental rep. $(2,7)$ |
| $\{0;-3,2\}$      | the adjoint representation $(1,14)$ |
| $\{1;0,0\}$       | the fundamental rep. $(2,1)$ |
| $\{0;-3,2\}, [0;2,-1]$ | the adjoint representation $(1,14)$ |
| $\{-1;0,0\}, [-1;2,-1]$ | the bifundamental rep. $(2,7)$ |

5 5d and 6d supergravity theories with eight supercharges

In this section, we determine the prepotential in each Coulomb branch of the five-dimensional supergravity theory with eight supercharges and match with the triple intersection polynomial for each corresponding crepant resolution. We determine the number of multiplets of the corresponding uplifted six-dimensional theory and check if the anomalies can be canceled using Green-Schwarz mechanism. We also explain the numerical oddities we encounter while counting the number of hypermultiplets.

5.1 5d $\mathcal{N}=1$ prepotentials

In the Coulomb phase of an $\mathcal{N}=1$ supergravity theory in five dimension, the scalar fields of the vector multiplets are restricted to the Cartan sub-algebra of the Lie group as the Lie group is broken to $U(1)^r$ where $r$ is the rank of the group. It follows that the charge of an hypermultiplet is simply given by a weight of the representation under which it transforms [53]. The Intrilligator-Morrison-Seiberg (IMS) prepotential is the quantum contribution to the prepotential of a five-dimensional gauge theory with the matter fields in the representations $R_i$ of the gauge group. Let $\phi$ be in the Cartan subalgebra of a Lie algebra $\mathfrak{g}$. The weights are in the dual space of the Cartan subalgebra. We denote the evaluation of a weight on a coroot vector $\phi$ as a scalar product $\langle \mu, \phi \rangle$. We recall that the roots are the weights of the adjoint representation of $\mathfrak{g}$. Denoting the fundamental simple roots by $\alpha$ and the weights of $R_i$ by $\varpi$ we have [53]

$$ 6\mathcal{F}_{\text{IMS}}(\phi) = \frac{1}{2} \left( \sum_\alpha |\langle \alpha, \phi \rangle|^3 - \sum_i \sum_{\varpi \in R_i} n_{R_i} |\langle \varpi, \phi \rangle|^3 \right). $$

(5.1)

For all simple groups with the exception of $SU(N)$ with $N \geq 3$, this is the full cubic prepotential as there are non-trivial third Casimir invariants.

The open dual fundamental Weyl chamber is defined as the cone $\langle \alpha, \phi \rangle > 0$, where $\alpha$ runs through the set of all simple positive roots. For a given choice of a group $G$ and
representations $R_i$, we have to determine a Weyl chamber to remove the absolute values in the sum over the roots. We then consider the hyperplane arrangement $\langle \varpi, \phi \rangle = 0$, where $\varphi$ runs through all the weights of all the representations $R_i$ and $\phi$ is an element of the coroot space. If none of these hyperplanes intersect the interior of the dual Weyl chamber of $g$, we can safely remove the absolute values in the sum over the weights. Otherwise, we have hyperplanes partitioning the dual fundamental Weyl chamber into subchambers. Each of these subchambers is defined by the signs of the linear forms $\langle \varpi, \phi \rangle$. Two such subchambers are adjacent when they differ by the sign of a unique linear form. Within each of these subchambers, the prepotential is a cubic polynomial. But as we go from one subchamber to an adjacent one, we have to go through one of the walls defined by the weights. The transition from one chamber to an adjacent chamber is a phase transition.

We compute $\mathcal{F}_{\text{IMS}}$ for each of the four chambers of an $SU(2) \times G_2$-model. The chambers are defined by table 3.

**Theorem 5.1.** The prepotential of an $SU(2) \times G_2$-model in the four phases defined by the chambers of table 3.

**Chamber 1:**

$$
6 \mathcal{F}_{\text{IMS}}^{(1)} = -4\phi_2^3(2n_{1,14} + n_{1,7} - 2) + 9\phi_1\phi_2^2(-2n_{1,14} + n_{1,7} + 2) - 8(n_{1,14} - 1)\phi_1^3
+ 3\phi_1^2\phi_2(8n_{1,14} - n_{1,7} - 8) + \psi_1^3(-n_{2,1} - 7n_{2,7} - 8n_{3,1} + 8)
+ 12\psi_1(-3n_{2,7}\phi_2^2 + 3n_{2,7}\phi_1\phi_2 - n_{2,7}\phi_1^2),
$$

**Chamber 2:**

$$
6 \mathcal{F}_{\text{IMS}}^{(2)} = -2\phi_2^3(4n_{1,14} + n_{1,7} - 1) + n_{2,7}) + 9\phi_1\phi_2^2(-2n_{1,14} + n_{1,7} + 2)
- 8(n_{1,14} - 1)\phi_1^3 + 3\phi_1^2\phi_2(8n_{1,14} - n_{1,7} - 8)
+ \psi_1^3(-n_{2,1} - 5n_{2,7} - 8n_{3,1} + 8) - 6n_{2,7}\psi_1^2\phi_2
+ \psi_1(-30n_{2,7}\phi_2^2 + 36n_{2,7}\phi_1\phi_2 - 12n_{2,7}\phi_1^2),
$$

**Chamber 3:**

$$
6 \mathcal{F}_{\text{IMS}}^{(3)} = 3\phi_1\phi_2^2(-6n_{1,14} + 3n_{1,7} - 2n_{2,7} + 6) + 3\phi_1^2\phi_2(8n_{1,14} - n_{1,7} + 2n_{2,7} - 8)
- 8\phi_2^3(n_{1,14} + n_{1,7} - 1) - 2\phi_1^3(4n_{1,14} + n_{2,7} - 4)
+ \psi_1^3(-n_{2,1} - 3n_{2,7} - 8n_{3,1} + 8)
+ \psi_1(-24n_{2,7}\phi_2^2 + 24n_{2,7}\phi_1\phi_2 - 6n_{2,7}\phi_1^2) - 6n_{2,7}\phi_1^2\phi_1,
$$

**Chamber 4:**

$$
6 \mathcal{F}_{\text{IMS}}^{(4)} = -8(n_{1,14} - 1)\phi_1^3 + 9\phi_1\phi_2^2(-2n_{1,14} + n_{1,7} + 2n_{2,7} + 2)
- 8\phi_2^3(n_{1,14} + n_{1,7} + 2n_{2,7} - 1) + 3\phi_2\phi_1^2(8n_{1,14} - n_{1,7} - 2n_{2,7} - 8)
+ \psi_1^3(-n_{2,1} - n_{2,7} - 8n_{3,1} + 8) - 12n_{2,7}\psi_1^2\phi_2.
$$

**Proof.** Direct computation starting with equation (5.1) and using table 3 to remove the absolute values.  \hfill \Box
The number of hypermultiplets are computed by comparing the prepotential and the intersection polynomial. Comparing the triple intersection numbers obtained in the Resolutions I, II, III, IV with the prepotentials computed respectively in Chambers 1, 2, 3, 4, we get
\[ n_{2,1} + 8n_{3,1} = S \cdot \left(4L + 2S - \frac{7}{2}T \right) + 8, \quad n_{1,14} = \frac{1}{2}(-L \cdot T + T^2 + 2), \]
\[ n_{2,7} = \frac{1}{2}S \cdot T, \quad n_{1,7} = T \cdot (5L - S - 2T). \]
(5.2)

We see in particular that the numbers \( n_{2,1} \) and \( n_{3,1} \) are not completely fixed by this method but restricted by a linear relation. The same is true for the SU(2)-model in [41]. Using Witten’s genus formula to restrict \( n_{3,1} \) with \( K = -L \), we get that \( n_{3,1} \) and \( n_{1,14} \) become respectively the arithmetic genus of the curves \( S \) and \( T \):
\[ n_{3,1} = g(S), \quad n_{1,14} = g(T), \quad n_{2,1} = -S \cdot \left(8K + 2S + \frac{7}{2}T \right), \quad n_{1,7} = -T \cdot (5K + S + 2T). \]
(5.3)

The geometric origin of the number \( n_{1,7} \) is as follows. The \( G_2 \) fiber contains a non-split curve that splits into three curves after an appropriate field extension. Over \( T \), this non-split curve defines a triple cover of \( T \) with a branch locus given by its discriminant \( s^3 t^6(4f^3 + 27g^2 s) \). The reduced discriminant is \( s(4f^3 + 27g^2 s) \) as \( t \) is a unit. Using Witten’s genus formula \([8, 75, 75]\), we get
\[ n_{1,7} = (d - 1)(g - 1) + \frac{1}{2} R, \]
(5.4)

where \( d = 3, \ g = \frac{1}{2}(KT + T^2 + 2), \) and the class of \( R \) is the class of the reduced discriminant, i.e. \( R = [t][s(4f^3 + 27g^2 s)] = -3T \cdot (4K + S + 2T) + S \cdot T. \)

As explained in remark 1.1, the representation \( n_{1,7} \) is frozen when \( S \) and \( T \) intersect transversally at one point and \( T \) is a \(-3\)-curve. The meaning of \( n_{2,1} \) is much more complicated. One would expect it to be just an intersection number, but that is not the case as will discuss in section 6.

### 5.2 Generalities on 6d \( \mathcal{N} = (1, 0) \) anomaly cancellations

We consider a gauged six-dimensional \( \mathcal{N} = (1, 0) \) supergravity theory \([48]\) with a semi-simple gauge group \( G = \prod_a G_a \), \( n_V^{(6)} \) vector multiplets, \( n_T \) tensor multiplets, and \( n_H \) hypermultiplets consisting of \( n_H^0 \) neutral hypermultiplets and \( n_H^1 \) charged hypermultiplets under a representation \( \bigoplus_i R_i \) of the gauge group with \( R_i = \bigotimes_a R_{i,a} \), where \( R_{i,a} \) is an irreducible representation of the simple component \( G_a \) of the semi-simple group \( G \). The vector multiplets transform under the adjoint of the gauge group. CPT invariance requires the representation to be quaternionic, and hence we have quaternions of dimension \( n_H \) for the hypermultiplets.

In particular, F-theory compactified on a Calabi-Yau threefold \( Y \) gives a six-dimensional supergravity theory with eight supercharges coupled to \( n_V \) vector, \( n_T \) tensor, and \( n_H^0 = h^{2,1}(Y) + 1 \) neutral hypermultiplets \([19]\). When the Calabi-Yau variety is elliptically fibered with a gauge group \( G \) and a representation \( R \), the number of vectors is
where \( R \) is a component of the group, it affects not only \( Y \) but also \( n \). Given by
\[
(n_H - n_V^{(6)} + 29n_T - 273)\text{tr}R^4
\]
the Green-Schwarz mechanism, the coefficient of \( \text{tr}R^4 \) is required to vanish [67]:
\[
n_H - n_V^{(6)} + 29n_T - 273 = 0. \tag{5.5}
\]
The remainder terms of the anomaly polynomial \( I_8 \), is given by
\[
I_8 = \frac{K^2}{8}(\text{tr}R^2)^2 + \frac{1}{6} \sum_a X_a^{(2)}\text{tr}R^2 - \frac{2}{3} \sum_a X_a^{(4)} + 4 \sum_{a < b} Y_{ab}, \tag{5.6}
\]
where each gauge group contributions \( X_a^{(n)} \) for \( n = 2, 4 \) and the mixed contribution \( Y_{ab} \) are given by
\[
X_a^{(n)} = \text{tr}_{adj}F_a^n - \sum_i n_{R_{i,a}}\text{tr}_{R_{i,a}}F_a^n, \quad Y_{ab} = \sum_{i,j} n_{R_{i,a}R_{j,b}}\text{tr}_{R_{i,a}}F_a^2\text{tr}_{R_{j,b}}F_b^2, \tag{5.7}
\]
and \( n_{R_{i,a}R_{j,b}} \) is the number of hypermultiplets transforming in the representation \( (R_{i,a}, R_{j,b}) \) of \( G_a \times G_b \).

It is important to note that when a representation is charged on more than a simple component of the group, it affects not only \( Y_{ab} \) but also \( X_a^{(2)} \) and \( X_a^{(4)} \). Consider a representation \( (R_1, R_2) \) for of a semisimple group with two simple components \( G = G_1 \times G_2 \), where \( R_a \) is a representation of \( G_a \). Then this representation contributes \( \dim R_2 \) times to \( n_{R_1} \), and contributes \( \dim R_1 \) times to \( n_{R_2} \):
\[
n_{R_1} = \cdots + \dim R_2 n_{R_1, R_2}, \quad n_{R_2} = \cdots + \dim R_1 n_{R_1, R_2}.
\]

By denoting the zero weights of a representation \( R_1 \) as \( R_1^{(0)} \), the charged dimension of the hypermultiplets in representation \( R_1 \) is given by \( \dim R_1 - \dim R_1^{(0)} \), since the hypermultiplets of zero weights are considered neutral. For a representation \( R_i \), \( n_{R_i} \) denotes the multiplicity of the representation \( R_i \). Then the number of charged hypermultiplets is as follows [47]
\[
n_H^{\text{ch}} = \sum_i n_{R_i} \left( \dim R_i - \dim R_i^{(0)} \right). \tag{5.8}
\]
The trace identities for a representation \( R_{i,a} \) of a simple group \( G_a \) are
\[
\text{tr}_{R_{i,a}}F_a^2 = A_{R_{i,a}}\text{tr}_{F_a}F_a^2, \quad \text{tr}_{R_{i,a}}F_a^4 = B_{R_{i,a}}\text{tr}_{F_a}F_a^4 + C_{R_{i,a}}(\text{tr}_{F_a}F_a^2)^2 \tag{5.9}
\]
with respect to a reference representation $F_a$ for each simple component $G_a$. These group theoretical coefficients are listed in \[9, 45, 72\].

We then have

$$X_a^{(2)} = (A_{a, \text{adj}} - \sum_i n_{R_i, a} A_{R_i, a}) \text{tr} F_a F_a^2,$$  \hspace{1cm} (5.10)

$$X_a^{(4)} = (B_{a, \text{adj}} - \sum_i n_{R_i, a} B_{R_i, a}) \text{tr} F_a F_a^4 + \left( C_{a, \text{adj}} - \sum_i n_{R_i, a} C_{R_i, a} \right) \left( \text{tr} F_a F_a^2 \right)^2,$$  \hspace{1cm} (5.11)

$$Y_{ab} = \sum_{i,j} n_{R_{i,a}, R_{j,b}} A_{R_{i,a}, A_{R_{j,b}}} \text{tr} F_a F_a^2 \text{tr} F_b F_b^2, \quad (a \neq b).$$  \hspace{1cm} (5.12)

For each simple component $G_a$, the anomaly polynomial $I_8$ has a pure gauge contribution proportional to the quartic term $\text{tr} F_a^4$ that is required to vanish in order to factorize $I_8$:

$$B_{a, \text{adj}} - \sum_i n_{R_i, a} B_{R_i, a} = 0.$$  

When the coefficients of all quartic terms ($\text{tr} R_4$ and $\text{tr} F_a^4$) vanish, the remaining part of the anomaly polynomial $I_8$ is

$$I_8 = \frac{K^2}{8} (\text{tr} R)^2 + \frac{1}{6} \sum_a X_a^{(2)} \text{tr} R^2 - \frac{2}{3} \sum_a X_a^{(4)} + 4 \sum_{a < b} Y_{ab},$$

$$X_a^{(2)} = (A_{a, \text{adj}} - \sum_i n_{R_i, a} A_{R_i, a}) \text{tr} F_a F_a^2,$$

$$X_a^{(4)} = \left( C_{a, \text{adj}} - \sum_i n_{R_i, a} C_{R_i, a} \right) \left( \text{tr} F_a F_a^2 \right)^2,$$

$$Y_{ab} = \sum_{i,j} n_{R_{i,a}, R_{j,b}} A_{R_{i,a}, A_{R_{j,b}}} \text{tr} F_a F_a^2 \text{tr} F_b F_b^2, \quad (a \neq b).$$  \hspace{1cm} (5.13)

The anomalies are canceled by the Green-Schwarz mechanism when $I_8$ factorizes \[48, 69, 70\]. The modification of the field strength $H$ of the antisymmetric tensor $B$ is

$$H = dB + \frac{1}{2} K \omega_{3L} + 2 \sum_a \frac{S_a}{\lambda_a} \omega_{a,3Y},$$  \hspace{1cm} (5.14)

where $\omega_{3L}$ and $\omega_{a,3Y}$ are respectively the gravitational and Yang-Mills Chern-Simons terms. If $I_8$ factors as

$$I_8 = X \cdot X,$$  \hspace{1cm} (5.15)

then the anomaly is canceled by adding the following Green-Schwarz counter-term

$$\Delta L_{GS} \propto \frac{1}{2} B \wedge X,$$  \hspace{1cm} (5.16)

which implies that $X$ carries string charges. Following Sadov \[68\], to cancel the local anomalies, we consider

$$X = \frac{1}{2} K \text{tr} R^2 + \sum_a \frac{2}{\lambda_a} S_a \text{tr} F_a^2,$$  \hspace{1cm} (5.17)

\[4\]We denoted this representation as $F_a$ as we picked the fundamental representations. However, any representation can be used as a reference representation.
where the \( \lambda_a \) are normalization factors chosen such that the smallest topological charge of an embedded SU(2) instanton in \( \mathcal{G}_a \) is one \([12, 58, 66]\). This forces \( \lambda_a \) to be the Dynkin index of the fundamental representation of \( \mathcal{G}_a \) as summarized in table 10 \([66]\).

If the simple group \( \mathcal{G}_a \) is supported on a divisor \( \mathcal{S}_a \), the local anomaly cancellation conditions are the following equations:

\[
\begin{align*}
  n_T &= 9 - K^2, \\
  n_H - n_V^{(6)} + 29n_T - 273 &= 0, \\
  \left( B_{a,\text{adj}} - \sum_i n_{R_{i,a}} B_{R_{i,a}} \right) &= 0, \\
  \lambda_a \left( A_{a,\text{adj}} - \sum_i n_{R_{i,a}} A_{R_{i,a}} \right) &= 6K \cdot S_a, \\
  \lambda_a^2 \left( C_{a,\text{adj}} - \sum_i n_{R_{i,a}} C_{R_{i,a}} \right) &= -3S_a^2, \\
  \lambda_a \lambda_b \sum_{i,j} n_{R_{i,a} R_{j,b}} A_{R_{i,a} A_{R_{j,b}}} &= S_a \cdot S_b, \quad (a \neq b).
\end{align*}
\]

Assuming the first three equations hold, canceling the anomalies is equivalent to factoring the anomaly polynomial

\[
I_8 = \frac{K^2}{8} (\text{tr} R^2)^2 + \frac{1}{6} (X_1^{(2)} + X_2^{(2)}) \text{tr} R^2 - \frac{2}{3} (X_1^{(4)} + X_2^{(4)}) + 4Y_{12}.
\]

The total number of hypermultiplets is the sum of the neutral hypermultiplets and the charged hypermultiplets. For a compactification on a Calabi-Yau threefold \( Y \), the number of neutral hypermultiplets is \( h^{2,1}(Y) + 1 \) \([19]\). The number of each multiplet is \([47]\)

\[
\begin{align*}
  n_V^{(6)} &= \dim G, \\
  n_T &= h^{1,1}(B) - 1 = 9 - K^2, \\
  n_H &= n_H^0 + n_H^{(b)} = h^{2,1}(Y) + 1 + \sum_i n_{R_i} \left( \dim R_i - \dim R_i^{(0)} \right),
\end{align*}
\]

where the (elliptically-fibered) base \( B \) is a rational surface.

### 5.3 Anomalies cancellations for an SU(2) \( \times G_2 \)-model

In this section, we check that the gravitational, gauged, and mixed anomalies of the six-dimensional supergravity are all canceled when the Lie algebra and the representation are

\[
g = A_1 \oplus G_2, \quad R = (3,1) \oplus (1,14) \oplus (2,1) \oplus (1,7) \oplus (2,7).
\]
First, we recall that for the case of a Calabi-Yau threefold (defined as a crepant resolution of the Weierstrass model of an SU(2)×G2-model), the Euler characteristic is (see Lemma 2.7)

\[ \chi(Y) = -6(10K^2 + 5K \cdot S + 8K \cdot T + S^2 + 2S \cdot T + 2T^2), \]  

(5.22)

where \( S \) and \( T \) are the curves supporting \( A_1 \) and \( G_2 \) respectively. The Hodge numbers are

\[ h^{1,1}(Y) = 14 - K^2, \quad h^{2,1}(Y) = 29K^2 + 15K \cdot S + 24K \cdot T + 3S^2 + 6S \cdot T + 6T^2 + 14. \]  

(5.23)

The numbers of vector multiplets and tensor multiplets, and neutral hypermultiplets are

\[ n_T = 9 - K^2, \quad n_V = \dim G = \dim SU(2) + \dim G_2 = 3 + 14 = 17, \]

\[ n_H^0 = h^{2,1}(Y) + 1 = 29K^2 + 15K \cdot S + 24K \cdot T + 3S^2 + 6S \cdot T + 6T^2 + 15. \]  

(5.24)

We will use the anomaly cancellation conditions to explicitly compute the number of hypermultiplets transforming in each representation by requiring all anomalies to cancel. We will see that they are the same as those found in five-dimensional supergravity by comparing the triple intersection numbers of the fibral divisors of a given crepant resolution and the cubic prepotential of the corresponding Coulomb chamber.

The Lie algebra of type \( A_1 \) (resp. \( G_2 \)) only has a unique quartic Casimir invariant so that we do not have to impose the vanishing condition for the coefficients of \( \text{tr} \ F_4 \) (resp. \( \text{tr} \ F_2^4 \)). We have the following trace identities for \( SU(2) \) and \( G_2 \) [9, 45]:

\[ \text{tr}_3 F_4^2 = 4\text{tr}_2 F_2^2, \quad \text{tr}_3 F_4^1 = 8(\text{tr}_3 F_2^2)^2, \quad \text{tr}_2 F_4^1 = \frac{1}{2}(\text{tr}_2 F_2^2)^2, \]

\[ \text{tr}_{14} F_2^2 = 4\text{tr}_7 F_2^2, \quad \text{tr}_{14} F_4^1 = \frac{5}{2}(\text{tr}_7 F_2^2)^2, \quad \text{tr}_7 F_4^1 = \frac{1}{4}(\text{tr}_7 F_2^2)^2, \]  

(5.25)

which give

\[ X^{(2)}_1 = (4 - 4n_{3,1} - n_{2,1} - 7n_{2,7}) \text{tr}_2 F_2^1, \]

\[ X^{(2)}_2 = (4 - 4n_{1,14} - n_{1,7} - 2n_{2,7}) \text{tr}_7 F_2^2, \]

\[ X^{(4)}_1 = \left(8 - 8n_{3,1} - \frac{1}{2}n_{2,1} - \frac{7}{2}n_{2,7}\right)(\text{tr}_2 F_2^1)^2, \]

\[ X^{(4)}_2 = \left(\frac{5}{2} - \frac{5}{2}n_{3,1} - \frac{1}{4}n_{1,7} - \frac{2}{4}n_{2,7}\right)(\text{tr}_7 F_2^2)^2, \]  

\[ Y_{27} = n_{2,7} \text{tr}_2 F_2^1 \text{tr}_7 F_2^2. \]  

(5.26)

Following table 10, we take \( \lambda_1 = 1 \) for \( A_1 \) and \( \lambda_2 = 2 \) for \( G_2 \). If the pure gravitational anomaly vanishes, the anomaly cancellation conditions are

\[ 2(4 - 4n_{1,14} - n_{1,7} - 2n_{2,7}) = 6K \cdot T, \quad (4 - 4n_{3,1} - n_{2,1} - 7n_{2,7}) = 6K \cdot S, \]

\[ (10 - 10n_{1,14} - n_{1,7} - 2n_{2,7}) = -3T^2, \quad \left(8 - 8n_{3,1} - \frac{1}{2}n_{2,1} - \frac{7}{2}n_{2,7}\right) = -3S^2, \]

\[ 2n_{2,7} = S \cdot T. \]  

(5.27)
These linear equations have the following unique solution
\[\begin{align*}
n_2\cdot 7 &= \frac{1}{2} S \cdot T, \\
n_{3,1} &= \frac{1}{2}(K \cdot S + S^2 + 2) \\
n_{2,1} &= -S \cdot \left( 8K + 2S + \frac{7}{2} T \right), \\
n_{1,14} &= \frac{1}{2}(K \cdot T + T^2 + 2), \\
n_{1,7} &= -T \cdot (5K + S + 2T).
\end{align*}\] (5.28)

We note that the numbers of charged hypermultiplets match exactly the values found in the five-dimensional theory (see equation (5.3)) after using Witten’s genus formula which asserts that the number of adjoint hypermultiplets \(n_{3,1}\) is the genus of the curve \(S\) supporting the group \(SU(2)\) [75].

We can now check that the pure gravitational anomaly is cancelled. The total number of hypermultiplets is the sum of the neutral hypermultiplets coming from the compactification and the charged hypermultiplets transforming under the different irreducible summands of the representation \(R\). Since the charge of a hypermultiplet is given by a weight of a representation, we remove the zero weights when counting charged hypermultiplets [47]. In the present case, we have:

\[n_H = n_H^0 + n_H^{ch} = (h_{2,1}^2(Y) + 1) + 2n_{2,1} + (7 - 1)n_{1,7} + 14n_{2,7} + (3 - 1)n_{3,1} + (14 - 2)n_{1,14}\] (5.29)

Using equation (5.24), we check that the coefficient of \(\text{tr} R^4\) vanishes as required by the cancellation of the pure gravitational anomaly [67]:

\[n_H - n_V + 29n_T - 273 = 0.\] (5.30)

Finally, we show that the anomaly polynomial \(I_8\) factors as a perfect square:

\[I_8 = \frac{K^2}{8} (\text{tr} R^2)^2 + \frac{1}{6} (X_1^{(2)} + X_2^{(2)}) \text{tr} R^2 - \frac{2}{3} (X_1^{(4)} + X_2^{(4)}) + 4Y_{27},\]

\[= \frac{1}{2} \left( \frac{1}{2} K \text{tr} R^2 + 2 \text{Str}_2 F_1^2 + T \text{tr}_T F_2^2 \right)^2.\] (5.31)

Hence, we conclude that all the local anomalies are canceled via the Green-Schwarz-Sagnotti-West mechanism [48, 69].

6 Counting hypermultiplets: numerical oddities

The physics of D-branes in presence of singularities is full of subtleties [2, 23, 40]. The situations that are well understood rely on fundamental physical properties such as the cancellations of anomalies and tadpoles or string dualities. For example, the induced D3-charge of a singular D7-brane is derived from a tadpole cancellation condition [2, 23].

The numbers of charged hypermultiplets we get from the triple intersection numbers of the five-dimensional theory match the numbers of hypermultiplets we get by solving the six-dimensional theory anomaly cancellation conditions. The number of fundamental \(n_{1,7}\)
can be explained using Witten’s genus formula and the number of bifundamental \( n_{2,7} \) is given by an intersection number as expected by the usual D-brane picture.

We point out an interesting observation about the number of hypermultiplets charged in the representation \((2,1)\) in the SU(2)×G\(_2\)-model. One would expect that the number of fundamental matter \( n_{2,1} \) is also given by a direct intersection number, but that is not the case. We cannot explain the number \( n_{2,1} \) by looking at the D-brane configuration attached to this geometry.

### 6.1 Determining \( n_{2,1} \) from triple intersection numbers in 5d or anomalies in 6d

If we evaluate the number of multiplets in a five-dimensional supergravity theory with eight supercharges resulting from a compactification of M-theory on an elliptically fibered Calabi-Yau threefold obtained by one of the resolution of the SU(2)×G\(_2\)-model, we can compare the triple intersection numbers of the divisors of the Calabi-Yau with the one-loop prepotential and deduce the number of multiplets. Moreover, in a compactification of F-theory on the same variety, we get a six-dimensional supergravity theory and we can use anomaly cancellation conditions to determine the number of hypermultiplets. In both cases, we find that \( n_{2,1} \) is given by

\[
 n_{2,1} = -2S \cdot (4K + S + \frac{7}{4}T) = -2S \cdot (4K + S + 2T) + \frac{1}{2} S \cdot T. \tag{6.1}
\]

### 6.2 Localization of hypermultiplets charged under the representation \((2,1)\)

We recall that the discriminant of the SU(2)×G\(_2\)-model is supported on three divisors, namely, \( S \) (which supports SU(2)), \( T \) (which supports G\(_2\)) and \( \Delta' = 4f^3 + 27g^2s \) (which does not support any gauge group). While \( S \) has a transverse intersection with \( T \), \( S \) intersects \( \Delta' \) non-transversally along triple points located at \( s = f = 0 \). The hypermultiplets transforming in the representation \((2,1)\) are localized at these non-transverse intersection points of \( S \) and \( \Delta' \). The divisor \( \Delta' \) has cuspidal singularities at \( V(f,g) \). However, since the divisor \( S \) intersects it along its smooth locus, the cuspidal points should not affect the discussion of the hypermultiplets charged under \((2,1)\).

The reduced locus of the intersection of \( S \) and \( \Delta' \) is \( V(s,f) \). One might think that following the usual D-brane picture, the number of hypermultiplets \( n_{2,1} \) will just be the intersection number

\[
 S \cdot [f] = -S \cdot (4K + S + 2T). \tag{6.1}
\]

We might also think that since the intersection of \( S \) and \( \Delta' \) is given by the non-reduced scheme \((s,f^3)\), we might take the multiplicity seriously and have

\[
 S \cdot [\Delta'] = -3S \cdot (4K + S + 2T). \tag{6.2}
\]

But what we get is

\[
 n_{2,1} = -2S \cdot (4K + S + 2T) + \frac{1}{2} S \cdot T. \tag{6.3}
\]

As discussed in remark 1.1, this formula reproduces what is known for the case when \( T \) and \( S \) are rational curves of self-intersection −2 and −3 intersecting transversally at one point \([21, 65]\).
Remark 6.1. There are two surprising numerical oddities about this formula (equation (6.3)).

1. The first oddity is the coefficient of 2 in the first term $-2S \cdot (4K + S + 2T)$.

2. The second numerical oddity is the presence of the second term as it predicts a nonzero number of hypermultiplets charged in the representation $(2, 1)$ even when the fiber of type III does not intersect the component $\Delta'$ and therefore does not enhance to a fiber of type IV.

We will discuss these two points further below using the geometric point of view of this paper, namely, the fiber geometry in a crepant resolution and the notion of saturations of weights.

6.3 Mismatch between the brane and the anomaly picture?

We can justify the contribution $-2S \cdot (4K + S + 2T)$ to $n_{2,1}$ by analyzing the crepant resolution. To be specific, we consider the case of the Resolution I studied in section 3.1. The fiber III consists of two curves, a projective line $(C_s^0)$ and a conic $(C_s^1)$:

$$C_s^1: e_1 = w_2 y^2 - t^2 s w_1 (f x + g t s) = 0.$$  \hfill (6.4)

The matrix of this conic is (with respect to the projective coordinates $[y : s : x]$):

$$M = \begin{pmatrix} w_2 & 0 & 0 \\ 0 & 0 & -\frac{1}{2} w_1 t^2 f \\ 0 & -\frac{1}{2} t^2 f w_1 & -t^3 g w_1 \end{pmatrix}. \hfill (6.5)$$

The determinant of this matrix is

$$\det M = -\frac{1}{4} w_2 w_1^2 t^4 f^2. \hfill (6.6)$$

The determinant of $M$ vanishes over two distinct loci in the base: the intersection $T \cap S$ (in particular $V(e_1, w_1 w_2 t)$) and the intersection of $S$ and $V(f)$ (located on $S$ and away from $T$).

At $f = 0$, $M$ has rank two and the conic splits into two lines inducing an enhancement

$$\text{III} \to \text{IV}. \hfill (6.7)$$

Each of the two line has weight $[1; 0; 0]$ since they are both away from the intersection with $T$ and each of them intersects $D_s^0$ transversally at one point (and therefore by linearity has intersection $-1$ with $D_s^1$).

The rank of the matrix $M$ collapses to two when $w_2 = 0$ and one when $w_1 = 0$. We recall that after the three blowups, the divisor $T$ has total transform $w_1 w_2 t$. Over $S \cap T$, the generic fiber $C_s^1$ of $D_s^1$ degenerates to a collection of four distinct rational curve with multiplicities. We are at the intersection of $S$ and $T$ and the fiber III collides with the fiber...
$I_0$ to produce a non-Kodaira fiber corresponding to a Kodaira fiber of type III* (whose dual graph $\tilde{E}_7$) with some components contracted to points.

$$III + I_0^* \rightarrow III^* \quad \text{with contracted components.} \quad (6.8)$$

Over $S \cap T$, the weights produced are in the adjoint representation $(1, 14)$ and the bi-fundamental representation $(2, 7)$. When $f = 0$, $C_1^s$ produces weights of the fundamental representation $(2, 1)$ of $SU(2) \times G_2$. One should keep in mind that the nonzero weights of the $(1, 7)$ are the short nonzero weights of the adjoint representation.

The discriminant of the conic indicates that the number of hypermultiplets in the representation $(2, 1)$ of $SU(2) \times G_2$ at points away from $T$ might be (taking into account the multiplicity of $f$ in $\det M$)

$$S \cdot [\det M] = -2S \cdot (4K + S + 2T). \quad (6.9)$$

In the expression of $n_{2,1}$ in equation (6.3), the first term $-2S \cdot (4K + S + 2T)$ is exactly the contribution from the discriminant of the conic away from the divisor $T$ seen in equation (6.9) when we take into account the multiplicity of $f^2$ in $\det M$. This explains the first numerical oddity mentioned in remark 6.1.

6.4 Hypers in the representation $(2, 1)$ at $S \cap T$?

The second term $\frac{1}{2} S \cdot T$ in equation (6.3) is a correction term that is equal to $n_{2,7}$, the number of hypermultiplets transforming in the bi-fundamental representation $(2, 7)$. This correction term gives an explicit mismatch with the number of hypermultiplets in the fundamental representation $n_{2,1}$ from what we expect from the D-brane picture which should be proportional to the intersection number computed in equation (6.9).

One might argue that this second term $\frac{1}{2} S \cdot T$ is an evidence of the existence of extra hypermultiplets transforming in the representation $(2, 1)$ that is localized at the intersection of $S$ and $T$. This argument is in direct conflict with the fibral geometry of the $SU(2) \times G_2$-model, since at the collision of $S$ and $T$, the geometry only predicts bifundamental matters in the representation $(2, 7)$.

Remark 6.2. The representation $2$ is a minuscule representation of $SU(2)$ and $7$ is a quasi-minuscule representation of $G_2$, in particular, the representation $7$ of $G_2$ has a zero weight and all the six remaining nonzero weights are in the same orbit of the Weyl group. The representation $(2, 7)$ is not a (quasi)-minuscule representation of $SU(2) \times G_2$ but its set of weights contains all the weights of the minuscule representation $(2, 1)$ of $SU(2) \times G_2$. We note that the set of weights of the representation $(2, 1)$ is a maximal subweight system of the set of weights of the representation $(2, 7)$. The weights of the representation $(2, 7)$ consists of two orbits under the Weyl group. One of the orbits has twelve elements that are the products of the weights of the $2$ of $SU(2)$ with the non-zero weights of the $7$ of $G_2$. There also exists an orbit that is consisted of exactly of the weights of the representation $(2, 1)$ and is obtained by the direct product of the weights of the $2$ of $SU(2)$ with the zero weight of the $7$ of $G_2$. It follows that the weights of the fundamental representation
(2, 1) are exactly the short weights of the bifundamental representation (2, 7). They form an orbit under the action of the Weyl group and the unique sub-system of weights of the representation (2, 7).

In the Resolution I, II, and III, the geometric weights in the representation (2, 7) are always weights of the representation (2, 7) that are not weights of the representation (2, 1). In contrast, in the Resolution IV, some of the rational curves that compose the singular fibers over $S \cap T$ have weights $[1; 0, 0]$, which is a weight of the representation (2, 1). However, on the same locus, we also get a rational curve with the weight $[-1; 2, -1]$, which belongs to the representation (2, 7). As summarized on table 8, the saturation of these two weights, $\{[1; 0, 0], [-1; 2, -1]\}$, is the full set of weights of the representation (2, 7) as can be seen directly by computing their Weyl orbits (see remark 6.2). We note that the representation (2, 7) was derived in all the three other chambers. Hence, finding (2, 7) on $S \cap T$ in Resolution IV is expected since the representations seen in F-theory should not depend on a choice of a crepant resolution, as each crepant resolution corresponds to a distinct Coulomb chamber of the same gauge theory.

In conclusion, the number of SU(2) fundamental hypermultiplets $n_{2,1}$ is not given by an intersection number. It has a correction that is at odd with the fibral geometry. While we see only the representation (2, 7) at the intersection $S \cap T$, we note that the representation (2, 1) is a minuscule representation of $SU(2) \times G_2$ and its weights form a subset of the weights of the representation (2, 7). In that sense, the weights of the representation (2, 1) are visible in all chambers even though they appear explicitly only as weights of vertical irreducible curves in the Resolution IV. It would be interesting to check if this phenomena occurs in other models with semi-simple Lie groups.
