Noise Contrastive Estimation and Negative Sampling for Conditional Models: Consistency and Statistical Efficiency

Zhuang Ma

Abstract

Noise Contrastive Estimation (NCE) is a powerful parameter estimation method for log-linear models, which avoids calculation of the partition function or its derivatives at each training step, a computationally demanding step in many cases. It is closely related to negative sampling methods, now widely used in NLP. This paper considers NCE-based estimation of conditional models. Conditional models are frequently encountered in practice; however there has not been a rigorous theoretical analysis of NCE in this setting, and we will argue there are subtle but important questions when generalizing NCE to the conditional case. In particular, we analyze two variants of NCE for conditional models: one based on a classification objective, the other based on a ranking objective. We show that the ranking-based variant of NCE gives consistent parameter estimates under weaker assumptions than the classification-based method; we analyze the statistical efficiency of the ranking-based and classification-based variants of NCE; finally we describe experiments on synthetic data and language modeling showing the effectiveness and trade-off of both methods.

1 Introduction

This paper considers parameter estimation in conditional models of the form

$$p(y|x; \theta) = \frac{\exp(s(x, y; \theta))}{Z(x; \theta)} \quad (1)$$

where \(s(x, y; \theta)\) is the unnormalized score of label \(y\) in conjunction with input \(x\) under parameters \(\theta\), \(\mathcal{Y}\) is a finite set of possible labels, and \(Z(x; \theta) = \sum_{y \in \mathcal{Y}} \exp(s(x, y; \theta))\) is the partition function for input \(x\) under parameters \(\theta\).

It is hard to overstate the importance of models of this form in NLP. In log-linear models, including both the original work on maximum-entropy models (Berger et al., 1996), and later work on conditional random fields (Lafferty et al., 2001), the scoring function \(s(x, y; \theta) = \theta \cdot f(x, y)\) where \(f(x, y) \in \mathbb{R}^d\) is a feature vector, and \(\theta \in \mathbb{R}^d\) are the parameters of the model. In more recent work on neural networks the function \(s(x, y; \theta)\) is a non-linear function. In Word2Vec the scoring function is \(s(x, y; \theta) = \theta_x \cdot \theta_y\) where \(y\) is a word in the context of word \(x\), and \(\theta_x \in \mathbb{R}^d\) and \(\theta_y \in \mathbb{R}^d\) are “inside” and “outside” word embeddings \(x\) and \(y\).

In many NLP applications the set \(\mathcal{Y}\) is large. Maximum likelihood estimation (MLE) of the parameters \(\theta\) requires calculation of \(Z(x; \theta)\) or its derivatives at each training step, thereby requiring a summation over all members of \(\mathcal{Y}\), which can be computationally expensive. This has led to many authors considering alternative methods, often referred to as “negative sampling methods”, where a modified training objective is used that does not require summation over \(\mathcal{Y}\) on each example. Instead negative examples are drawn from some distribution, and a objective function is derived based on binary classification or ranking. Prominent examples are the binary objective used in word2vec ((Mikolov et al., 2013), see also (Levy and Goldberg, 2014)), and the Noise Contrastive Estimation methods of (Mnih and Teh, 2012; Jozefowicz et al., 2016) for estimation of language models.

In spite of the centrality of negative sampling methods, they are arguably not well understood from a theoretical standpoint. There are clear connections to noise contrastive estimation (NCE) (Gutmann and Hyvärinen, 2012), a negative sampling method for parameter estimation in joint models of the form

$$p(y) = \frac{\exp(s(y; \theta))}{Z(\theta)}; \quad Z(\theta) = \sum_{y \in \mathcal{Y}} \exp(s(y; \theta)) \quad (2)$$

However there has not been a rigorous theoretical analysis of NCE in the estimation of conditional models of the form in Eq. 1, and we will argue there are subtle but important questions when generalizing NCE to the conditional case. In particular, the joint model in Eq 2 has a single partition function \(Z(\theta)\) which is estimated as a param-

*Part of this work done at Google.
†Work done at Google.
eter of the model (Gutmann and Hyvärinen, 2012) whereas the conditional model in Eq 1 has a separate partition function $Z(x; \theta)$ for each value of $x$. This difference is critical.

We show the following (throughout we define $K \geq 1$ to be the number of negative examples sampled per training example):

- For any $K \geq 1$, a binary classification variant of NCE, as used by (Mnih and Teh, 2012; Mikolov et al., 2013), gives consistent parameter estimates under the assumption that $Z(x; \theta)$ is constant with respect to $x$ (i.e., $Z(x; \theta) = H(\theta)$ for some function $H$). Equivalently, the method is consistent under the assumption that the function $s(x, y; \theta)$ is powerful enough to incorporate $\log Z(x; \theta)$.

- For any $K \geq 1$, a ranking-based variant of NCE, as used by (Jozefowicz et al., 2016), gives consistent parameter estimates under the much weaker assumption that $Z(x; \theta)$ can vary with $x$. Equivalently, there is no need for $s(x, y; \theta)$ to be powerful enough to incorporate $\log Z(x; \theta)$.

- We analyze the statistical efficiency of the ranking-based and classification-based NCE variants. Under respective assumptions, both variants achieve Fisher efficiency (the same asymptotic mean square error as the MLE) as $K \to \infty$.

- We discuss application of our results to approaches of (Mnih and Teh, 2012; Mikolov et al., 2013; Levy and Goldberg, 2014; Jozefowicz et al., 2016) giving a unified account of these methods.

- We describe experiments on synthetic data and language modeling evaluating the effectiveness of the two NCE variants.

2 Basic Assumptions

We assume the following setup throughout:

- We have sets $\mathcal{X}$ and $\mathcal{Y}$, where $\mathcal{X}, \mathcal{Y}$ are finite.

- There is some unknown joint distribution $p_{X,Y}(x, y)$ where $x \in \mathcal{X}$ and $y \in \mathcal{Y}$. We assume that the marginal distributions satisfy $p_X(x) > 0$ for all $x \in \mathcal{X}$ and $p_Y(y) > 0$ for all $y \in \mathcal{Y}$.

- We have training examples $\{(x^{(i)}, y^{(i)})\}_{i=1}^n$ drawn I.I.D. from $p_{X,Y}(x, y)$.

- We have a scoring function $s(x, y; \theta)$ where $\theta$ are the parameters of the model. For example, $s(x, y; \theta)$ may be defined by a neural network.

- We use $\Theta$ to refer to the parameter space. We assume that $\Theta \subseteq \mathbb{R}^d$ for some integer $d$.

- We use $p_N(y)$ to refer to a distribution drawn from which negative examples are drawn in the NCE approach. We assume that $p_N$ satisfies $p_N(y) > 0$ for all $y \in \mathcal{Y}$.

We will consider estimation under the following two assumptions:

**Assumption 2.1** There exists some parameter value $\theta^* \in \Theta$ such that for all $(x, y) \in \mathcal{X} \times \mathcal{Y}$,

$$p_{Y \mid X}(y|x) = \frac{\exp(s(x, y; \theta^*))}{Z(x; \theta^*)}$$ (3)

where $Z(x; \theta) = \sum_{y \in \mathcal{Y}} \exp(s(x, y; \theta^*))$.

**Assumption 2.2** There exists some parameter value $\theta^* \in \Theta$, and a constant $\gamma^* \in \mathbb{R}$, such that for all $(x, y) \in \mathcal{X} \times \mathcal{Y}$,

$$p_{Y \mid X}(y|x) = \exp(s(x, y; \theta^*) - \gamma^*)$$ (4)

Assumption 2.2 is stronger than Assumption 2.1. It requires $\log Z(x; \theta^*) = \gamma^*$ for all $x, y$, i.e., the conditional distribution is perfectly self-normalized. Under Assumption 2.2, it must be the case that $\forall x \in \mathcal{X}

$$\sum_{y} p_{Y \mid X}(y|x) = \sum_{y} \exp\{s(x, y; \theta^*) - \gamma^*\} = 1$$

There are $|\mathcal{X}|$ constraints but only $d + 1$ free parameters. Therefore self-normalization is a non-trivial assumption when $|\mathcal{X}| \gg d$. In the case of language modeling, $|\mathcal{X}| = |V|^k \gg d + 1$, where $|V|$ is the vocabulary size and $k$ is the length of the context. The number of constraints grows exponentially fast.

Given a scoring function $s(x, y; \theta)$ that satisfies assumption 2.1, we can derive a scoring function $s'$ that satisfies assumption 2.2 by defining

$$s'(x, y; \theta; \{c_x : x \in \mathcal{X}\}) = s(x, y; \theta) - c_x$$

where $c_x \in \mathbb{R}$ is a parameter for history $x$. Thus we introduce a new parameter $c_x$ for each possible history $x$. This is the most straightforward extension of NCE to the conditional case; it is used by (Mnih and Teh, 2012). It has the clear drawback however of introducing a large number of additional parameters to the model.

3 Two Estimation Algorithms

Figure 1 shows two NCE-based parameter estimation algorithms, based respectively on binary objective and ranking objective. The input to either algorithm is a set of training examples $\{x^{(i)}, y^{(i)}\}_{i=1}^n$, a parameter $K$ specifying the number of negative examples per training example, and
a distribution \( p_N(\cdot) \) from which negative examples are sampled. The algorithms differ only in the choice of objective function being optimized: \( L^B \) for binary objective, and \( L^R \) for ranking objective. Binary objective essentially corresponds to a problem where the scoring function \( s(x, y; \theta) \) is used to construct a binary classifier that discriminates between positive and negative examples. Ranking objective corresponds to a problem where the scoring function \( s(x, y; \theta) \) is used to rank the true label \( y^{(i)} \) above negative examples \( y^{(i,1)} \ldots y^{(i,K)} \) for the input \( x^{(i)} \).

Our main result is as follows:

**Theorem 3.1** (Informal: see section 4 for a formal statement.) For any \( K \geq 1 \), the binary classification-based algorithm in figure 1 is consistent under Assumption 2.2, but is not always consistent under the weaker Assumption 2.1. For any \( K \geq 1 \), the ranking-based algorithm in figure 1 is consistent under either Assumption 2.1 or Assumption 2.2. Both algorithms achieve the same statistical efficiency as the maximum-likelihood estimate as \( K \to \infty \).

The remainder of this section gives a sketch of the argument underlying consistency, and discusses use of the two algorithms in previous work.

### 3.1 A Sketch of the Consistency Argument for the Ranking-Based Algorithm

In this section, in order to develop intuition underlying the ranking algorithm, we give a proof sketch of the following theorem:

**Theorem 3.2** (First part of theorem 4.1 below.) Define \( L^R_N(\theta) = \mathbb{E}[\mathcal{L}^R_n(\theta)] \). Under Assumption 2.1, \( \hat{\theta} \in \arg\max_\theta \mathcal{L}^R_N(\theta) \) if and only if, for all \((x, y) \in \mathcal{X} \times \mathcal{Y}\),

\[
p_{Y|X}(y|x) = \frac{\exp(s(x, y; \hat{\theta}))}{Z(x, \hat{\theta})}.
\]

This theorem is key to the consistency argument. Intuitively as \( n \) increases \( \mathcal{L}^R_N(\theta) \) converges to \( \mathcal{L}^R(\theta) \), and the output to the algorithm converges to \( \theta' \) such that \( p(y|x; \theta') = p_{Y|X}(y|x) \) for all \( x, y \).

Section 4 gives a formal argument.

We now give a proof sketch for theorem 3.2. Consider the algorithm in figure 1. For convenience define \( \bar{y}^{(i)} \) to be the vector \((y^{(i,0)}, y^{(i,1)}, \ldots, y^{(i,K)})\). Define \( \alpha(x, \bar{y}) = \)

| Inputs: | Training examples \( \{x^{(i)}, y^{(i)}\}_{i=1}^n \), sampling distribution \( p_N(\cdot) \) for generating negative examples, an integer \( K \) specifying the number of negative examples per training example, a scoring function \( s(x, y; \theta) \). Flags \{BINARY = true, RANKING = false\} if binary classification objective is used, \{BINARY = false, RANKING = true\} if ranking objective is used. |
| Definitions: | Define \( \bar{s}(x, y; \theta) = s(x, y; \theta) - \log p_N(y) \) |
| Algorithm: | - For \( i = 1 \ldots n, k = 1 \ldots K \), draw \( y^{(i,k)} \) IID from the distribution \( p_N(y) \). For convenience define \( y^{(i,0)} = y^{(i)} \).
  - If RANKING, define the ranking objective function
    \[
    \mathcal{L}^R_n(\theta) = \frac{1}{n} \sum_{i=1}^n \log \sum_{k=0}^K \exp(s(x^{(i)}, y^{(i,k)}; \theta)) - \log \left( 1 - \exp(s(x^{(i)}, y^{(i,0)}; \theta)) \right),
    \]
    and the estimator \( \hat{\theta}_R = \arg\max_{\theta \in \Theta} \mathcal{L}^R_n(\theta) \).
  - If BINARY, define the binary objective function
    \[
    \mathcal{L}^B_n(\theta, \gamma) = \frac{1}{n} \sum_{i=1}^n \left\{ \log g(x^{(i)}, y^{(i,0)}; \theta, \gamma) + \sum_{k=1}^K \log \left( 1 - \exp(s(x^{(i)}, y^{(i,k)}; \theta, \gamma)) \right) \right\},
    \]
    and estimator \( \hat{\theta}_B, \hat{\gamma}_B = \arg\max_{\theta, \gamma} \mathcal{L}^B_n(\theta, \gamma) \) where \( \theta \in \Theta, \gamma \in \Gamma \) and \( g(x, y; \theta, \gamma) = \frac{\exp(\bar{s}(x, y; \theta) - \gamma)}{\exp(\bar{s}(x, y; \theta) - \gamma) + 1} \).
  - Define \( \hat{\theta} = \hat{\theta}_B \) if RANKING and \( \hat{\theta} = \hat{\theta}_B \) otherwise. Return \( \hat{\theta} \).
  - Define \( \hat{\theta} = \hat{\theta}_B \) if RANKING and \( \hat{\theta} = \hat{\theta}_B \) otherwise. Return \( \hat{\theta} \).

Figure 1: Two NCE-based estimation algorithms, using ranking objective and binary objective respectively.
distributions over the true label \( k \in \{0 \ldots K\} \) given an input \( x, \bar{y} \), under the parameters \( \theta \) and the true distributions \( p_X \bar{y}(x, \bar{y}) \) respectively; \( C(x, \bar{y}; \theta) \) is the negative cross-entropy between these two distributions.

The proof of theorem 3.2 rests on two identities. The first identity states that the objective function is the expectation of the negative cross-entropy w.r.t. the density function \( \frac{1}{K+1} \alpha(x, \bar{y}) \) (see Section B.1.1 of the supplementary material for derivation):

\[
\mathcal{L}_R^\infty(\theta) = \sum_x \sum_{\bar{y}} \frac{1}{K+1} \alpha(x, \bar{y}) C(x, \bar{y}; \theta). \tag{5}
\]

The second identity concerns the relationship between \( q(k|x, \bar{y}; \theta) \) and \( \beta(|x, \bar{y}) \). Under assumption 2.1, for all \( x, \bar{y}, k \in \{0 \ldots K\} \),

\[
q(k|x, \bar{y}; \theta^*) = \frac{p_{\theta^*}|X(\bar{y}k|x)Z(x; \theta^*)/p_N(\bar{y}k)}{\sum_{k=0}^K p_{\theta^*}|X(\bar{y}k|x)Z(x; \theta^*)/p_N(\bar{y}k)} = \beta(k|x, \bar{y}) \tag{6}
\]

It follows immediately through the properties of negative cross entropy that

\[
\forall x, \bar{y}, \theta^* \in \arg\max_\theta C(x, \bar{y}; \theta) \tag{7}
\]

The remainder of the argument is as follows:

- Eqs. 7 and 5 imply that \( \theta^* \in \arg\max_\theta \mathcal{L}_R^\infty(\theta) \).
- Assumption 2.1 implies that \( \alpha(x, \bar{y}) > 0 \) for all \( x, \bar{y} \). It follows that any \( \theta' \in \arg\max_\theta \mathcal{L}_R^\infty(\theta) \) satisfies

\[
q(k|x, \bar{y}; \theta') = q(k|x, \bar{y}; \theta^*) = \beta(k|x, \bar{y}) \tag{8}
\]

Otherwise there would be some \( x, \bar{y} \) such that \( C(x, \bar{y}; \theta') < C(x, \bar{y}; \theta^*) \).

- Eq. 8 implies that \( \forall x, y, p(y|x; \theta') = p(y|x; \theta^*) \). See the proof of lemma B.3 in the supplementary material.

In summary, the identity in Eq. 5 is key: the objective function in the limit, \( \mathcal{L}_R^\infty(\theta) \), is related to a negative cross-entropy between the underlying distribution \( \beta(|x, \bar{y}) \) and a distribution under the parameters, \( q(|x, \bar{y}; \theta) \). The parameters \( \theta^* \) maximize this negative cross entropy over the space of all distributions \( \{q(|x, \bar{y}; \theta), \theta \in \Theta\} \).

### 3.2 The Algorithms in Previous Work

To motivate the importance of the two algorithms, we now discuss their application in previous work.

Mnih and Teh (2012) consider language modeling, where \( x = w_1w_2 \ldots w_{n-1} \) is a history consisting of the previous \( n-1 \) words, and \( y \) is a word. The scoring function is defined as

\[
s(x, y; \theta) = \left( \sum_{i=1}^{n-1} C_i r_{w_i} \right) q_y + b_y - c_x
\]

where \( r_{w_i} \) is an embedding (vector of parameters) for history word \( w_i \), \( q_y \) is an embedding (vector of parameters) for word \( y \), each \( C_i \) for \( i = 1 \ldots n-1 \) is a matrix of parameters specifying the contribution of \( r_{w_i} \) to the history representation, \( b_y \) is a bias term for word \( y \), and \( c_x \) is a parameter corresponding to the log normalization term for history \( x \). Thus each history \( x \) has its own parameter \( c_x \). The binary objective function is used in the NCE algorithm. The noise distribution \( p_N(y) \) is set to be the unigram distribution over words in the vocabulary.

This method is a direct application of the original NCE method to conditional estimation, through introduction of the parameters \( c_x \) corresponding to normalization terms for each history. Interestingly, Mnih and Teh (2012) acknowledge the difficulties in maintaining a separate parameter \( c_x \) for each history, and set \( c_x = 0 \) for all \( x \), noting that empirically this works well, but without giving justification.

Mikolov et al. (2013) consider an NCE-based method using the binary objective function for estimation of word embeddings. The skip-gram method described in the paper corresponds to a model where \( x \) is a word, and \( y \) is a word in the context. The vector \( v_x \) is the embedding for word \( x \), and the vector \( v'_y \) is an embedding for word \( y \) (separate embeddings are used for \( x \) and \( y \)). The method they describe uses

\[
\tilde{s}(x, y; \theta) = v'_y \cdot v_x
\]

or equivalently

\[
s(x, y; \theta) = v'_y \cdot v_x + \log p_N(y)
\]

The negative-sampling distribution \( p_N(y) \) was chosen as the unigram distribution \( p_N(y) \) raised to the power 3/4. The end goal of the method was to learn useful embeddings \( v_w \) and \( v'_w \) for each word
in the vocabulary; however the method gives a consistent estimate for a model of the form

\[ p(y|x) = \frac{\exp(v'_y \cdot v_x + \log p_N(y))}{\sum_y \exp(v'_y \cdot v_x + \log p_N(y))} = \frac{p_N(y) \exp(v'_y \cdot v_x)}{Z(x; \theta)} \]

assuming that Assumption 2.2 holds, i.e.

\[ Z(x; \theta) = \sum_y p_N(y) \exp(v'_y \cdot v_x) \equiv H(\theta) \]

which does not vary with \( x \).

Levy and Goldberg (2014) make a connection between the NCE-based method of (Mikolov et al., 2013), and factorization of a matrix of pointwise mutual information (PMI) values of \((x, y)\) pairs. Consistency of the NCE-based method under assumption 2.2 implies a similar result, specifically: if we define \( p_N(y) = p_Y(y) \), and define \( s(x, y; \theta) = v'_y \cdot v_x + \log p_N(y) \) implying \( \bar{s}(x, y; \theta) = v'_y \cdot v_x \), then parameters \( v'_y \) and \( v_x \) converge to values such that

\[ p(y|x) = \frac{p_Y(y) \exp(v'_y \cdot v_x)}{H(\theta)} \]

or equivalently

\[ \text{PMI}(x, y) = \log \frac{p(y|x)}{p(y)} = v'_y \cdot v_x - \log H(\theta) \]

That is, following (Levy and Goldberg, 2014), the inner product \( v'_y \cdot v_x \) is an estimate of the PMI up to a constant offset \( H(\theta) \).

Finally, Jozefowicz et al. (2016) introduce the ranking-based variant of NCE for the language modeling problem. This is the same as the ranking-based algorithm in figure 1. They do not, however, make the connection to assumptions 2.2 and 2.1, or derive the consistency or efficiency results in the current paper. Jozefowicz et al. (2016) partially motivate the ranking-based variant through the importance sampling viewpoint of Bengio and Senécal (2008). However there are two critical differences: 1) the algorithm of Bengio and Senécal (2008) does not lead to the same objective \( L^*_R \) in the ranking-based variant of NCE; instead it uses importance sampling to derive an objective that is similar but not identical; 2) the importance sampling method leads to a biased estimate of the gradients of the log-likelihood function, with the bias going to zero only as \( K \to \infty \).

In contrast the theorems in the current paper show that the NCE-based methods are consistent for any value of \( K \). In summary, while it is tempting to view the ranking variant of NCE as an importance sampling method, the NCE-based view gives stronger guarantees for finite values of \( K \).

4 Theory

This section states the main theorems. The supplementary material contains proofs. Throughout the paper, we use \( E_X[\cdot], E_Y[\cdot], E_{X,Y}[\cdot], E_{Y|X=x}[\cdot] \) to represent the expectation w.r.t. \( p_X(\cdot), p_Y(\cdot), p_{X,Y}(\cdot, \cdot), p_{Y|X}(\cdot|x) \). We use \( || \cdot || \) to denote either the \( l_2 \) norm when the operand is a vector or the spectral norm when the operand is a matrix.

Finally, we use \( \Rightarrow \) to represent converge in distribution. Recall that we have defined

\[ \bar{s}(x, y; \theta) = s(x, y; \theta) - \log p_N(y) \]

4.1 Ranking

In this section, we study noise contrastive estimation with ranking objective under Assumption 2.1.

First consider the following function:

\[ L_R^n(\theta) = \sum_{x,0,\ldots,0} p_{X,Y}(x, y_0) \prod_{i=1}^K p_N(y_i) \times \log \left( \frac{\exp(\bar{s}(x, y_0; \theta))}{\sum_{k=0}^K \exp(\bar{s}(x, y_k; \theta))} \right) \]

By straightforward calculation, one can find that

\[ L_R^n(\theta) = E[L_R^\infty(\theta)] \]

Under mild conditions, \( L_R^n(\theta) \) converges to \( L_R^\infty(\theta) \) as \( n \to \infty \). Denote the set of maximizers of \( L_R^\infty(\theta) \) by \( \Theta_R^* \), that is

\[ \Theta_R^* = \arg \max_{\theta \in \Theta} L_R^\infty(\theta) \]

The following theorem shows that any parameter vector \( \tilde{\theta} \in \Theta_R^* \) if and only if it gives the correct conditional distribution \( p_{Y|X}(y|x) \).

Assumption 4.1 (Identifiability). For any \( \theta \in \Theta \), if there exists a function \( c(x) \) such that \( s(x, y; \theta) - s(x, y; \theta^*) \equiv c(x) \) for all \( (x, y) \in X \times Y \), then \( \theta = \theta^* \) and thus \( c(x) = 0 \) for all \( x \).

Theorem 4.1 Under Assumption 2.1, \( \tilde{\theta} \in \Theta_R^* \) if and only if, for all \( (x, y) \in X \times Y \),

\[ p_{Y|X}(y|x) = \exp(s(x, y; \tilde{\theta}))/Z(x, \tilde{\theta}) \]

In addition, \( \Theta_R^* \) is a singleton if and only if Assumption 4.1 holds.
Next we consider consistency of the estimation algorithm based on the ranking objective under the following regularity assumptions:

**Assumption 4.2** (Continuity). \(s(x, y; \theta)\) is continuous w.r.t. \(\theta\) for all \((x, y) \in X \times Y\).

**Assumption 4.3** \(\Theta^*_k\) is contained in the interior of a compact set \(\Theta \subset \mathbb{R}^d\).

For a given estimate \(\hat{p}_{Y|X}\) of the conditional distribution \(p_{Y|X}\), define the error metric \(d(\cdot, \cdot)\) by
\[
d(\hat{p}_{Y|X}, p_{Y|X}) = \sum_{x \in X, y \in Y} p_{X,Y}(x,y) \times (\hat{p}_{Y|X}(y|x) - p_{Y|X}(y|x))^2.
\]

For a sequence of IID observations \((x^{(1)}, y^{(1)}), (x^{(2)}, y^{(2)}), \ldots\), define the sequences of estimates \((\hat{\theta}^1_{R}, \hat{p}^1_{Y|X}), (\hat{\theta}^2_{R}, \hat{p}^2_{Y|X}), \ldots\) where the \(n^{th}\) estimate \((\hat{\theta}^n_{R}, \hat{p}^n_{Y|X})\) is obtained by optimizing the ranking objective of figure 1 on \((x^{(1)}, y^{(1)}), (x^{(2)}, y^{(2)}), \ldots, (x^{(n)}, y^{(n)})\).

**Theorem 4.2** (Consistency) Under Assumptions 2.1, 4.2, 4.3, the estimates based on the ranking objective are strongly consistent in the sense that for any fixed \(K \geq 1\),
\[
\mathbb{P}\left\{ \lim_{n \to \infty} \min_{\theta \in \Theta^*_K} \| \hat{\theta}^n_{R} - \theta^* \| = 0 \right\} = \mathbb{P}\left\{ \lim_{n \to \infty} d(\hat{\theta}^n_{R}, p_{Y|X}) = 0 \right\} = 1
\]

Further, if Assumption 4.1 holds,
\[
\mathbb{P}\left\{ \lim_{n \to \infty} \hat{\theta}^n_{R} = \theta^* \right\} = 1.
\]

**Remark 4.1** Thoughout the paper, all NCE estimators are defined for some fixed \(K\). We suppress the dependence on \(K\) to simplify notation (e.g. \(\hat{\theta}^n_{R}\) should be interpreted as \(\hat{\theta}^n_{R,K}\)).

### 4.2 Classification

Now we turn to the analysis of NCE with binary objective under Assumption 2.2. First consider the following function,
\[
L_B^n(\theta, \gamma) = \sum_{x,y} \left\{ p_{X,Y}(x,y) \log (g(x,y;\theta,\gamma)) + K p_X(x) p_N(y) \log (1 - g(x,y;\theta,\gamma)) \right\}
\]

One can find that
\[
L_B^n(\theta, \gamma) = \mathbb{E} [L_B^n(\theta, \gamma)].
\]

Denote the set of maximizers of \(L_B^n(\theta, \gamma)\) by \(\Omega_B^*\):
\[
\Omega_B^* = \arg \max_{\theta \in \Theta, \gamma \in \Gamma} L_B^n(\theta, \gamma).
\]

Parallel results of Theorem 4.1, 4.2 are established as follows.

**Assumption 4.4** (Identifiability). For any \(\theta \in \Theta\), if there exists some constant \(c\) such that \(s(x, y; \theta) - s(x, y; \theta^*) \equiv c\) for all \((x, y) \in X \times Y\), then \(\theta = \theta^*\) and thus \(c = 0\).

**Assumption 4.5** \(\Omega_B^*\) is in the interior of \(\Theta \times \Gamma\) where \(\Theta \subset \mathbb{R}^d, \Gamma \subset \mathbb{R}\) are compact sets.

**Theorem 4.3** Under Assumption 2.2, \((\hat{\theta}, \gamma)\) \(\in\) \(\Omega_B^*\) if and only if, for all \((x, y) \in X \times Y\),
\[
p_{Y|X}(y|x) = \exp(s(x, y; \hat{\theta}) - \gamma)
\]

for all \((x, y)\). \(\Omega_B^*\) is a singleton if and only if Assumption 4.4 holds.

Similarly we can define the sequence of estimates \((\hat{\theta}^n_B, \hat{\gamma}^n_B, \hat{p}^n_{Y|X}), (\hat{\theta}^n_B, \hat{\gamma}^n_B, \hat{p}^n_{Y|X})\) based on the binary objective.

**Theorem 4.4** (Consistency) Under Assumptions 2.2, 4.2, 4.5, the estimates defined by the binary objective are strongly consistent in the sense that for any \(K \geq 1\),
\[
\mathbb{P}\left\{ \lim_{n \to \infty} \min_{(\theta^*, \gamma^*) \in \Omega_B^*} \| (\hat{\theta}^n_B, \hat{\gamma}^n_B) - (\theta^*, \gamma^*) \| = 0 \right\} = \mathbb{P}\left\{ \lim_{n \to \infty} d(\hat{\theta}^n_{R}, p_{Y|X}) = 0 \right\} = 1
\]

If further Assumption 4.4 holds,
\[
\mathbb{P}\left\{ \lim_{n \to \infty} (\hat{\theta}^n_B, \hat{\gamma}^n_B) = (\theta^*, \gamma^*) \right\} = 1.
\]

### 4.3 Counterexample

In this section, we give a simple example to demonstrate that the binary classification approach fails to be consistent when assumption 2.1 holds but assumption 2.2 fails (i.e. the partition function depends on the input).

Consider \(X \in \{x_1, x_2\}\) with marginal distribution
\[
p_X(x_1) = p_X(x_2) = 1/2,
\]
and \(Y \in \{y_1, y_2\}\) generated by the conditional model specified in assumption 2.1 with the score function parametrized by \(\theta = (\theta_1, \theta_2)\) and
\[
s(x_1, y_1; \theta) = \log \theta_1,
\]
\[
s(x_2, y_2; \theta) = \log \theta_2.
\]
Assume the true parameter is \(\theta^* = (\theta_1^*, \theta_2^*) = (1, 3)\). By simple calculation,

\[
Z(\theta^*; x_1) = 4, \quad Z(\theta^*; x_2) = 6,
\]

\[
p_{X,Y}(x_1, y_1) = 1/8, \quad p_{X,Y}(x_1, y_2) = 3/8,
\]

\[
p_{X,Y}(x_2, y_1) = p_{X,Y}(x_2, y_2) = 1/4.
\]

Suppose we choose the negative sampling distribution \(p_N(y_1) = p_N(y_2) = 1/2\). For any \(K \geq 1\), by the Law of Large Numbers, as \(n\) goes to infinity, \(L_B^\infty(\theta, \gamma)\) will converge to \(L_B^\infty(\theta, \gamma)\). Substitute the parameters in the above. One can show that

\[
L_B^\infty(\theta, \gamma) = \frac{1}{8} \log 2 + \frac{K}{4} \log \left( \frac{\exp(\gamma)}{2 \theta_1 + K \exp(\gamma)} \right) + \frac{7}{8} \log \left( \frac{\exp(\gamma)}{2 \theta_2 + K \exp(\gamma)} \right) + \frac{3K}{4} \log \left( \frac{\exp(\gamma)}{2 \theta_2 + K \exp(\gamma)} \right).
\]

Setting the derivatives w.r.t. \(\theta_1, \theta_2\) to zero, one will obtain

\[
\theta_1 = \frac{1}{4} \exp(\gamma), \quad \theta_2 = \frac{7}{12} \exp(\gamma).
\]

So for any \((\hat{\theta}_1, \hat{\theta}_2, \hat{\gamma}) \in \arg\max_{\theta, \gamma} L_B^\infty(\theta, \gamma), (\tilde{\theta}_1, \tilde{\theta}_2, \tilde{\gamma})\) will satisfy the equalities above. Then the estimated distribution \(\tilde{p}_{Y|X}\) will satisfy

\[
\frac{\tilde{p}_{Y|X}(y_1|x_1)}{\tilde{p}_{Y|X}(y_2|x_1)} = \frac{\hat{\theta}_1}{\hat{\theta}_2} = \frac{1/4}{7/12} = \frac{3}{7},
\]

which contradicts the fact that

\[
\frac{p_{Y|X}(y_1|x_1)}{p_{Y|X}(y_2|x_1)} = \frac{p_{X,Y}(x_1, y_1)}{p_{X,Y}(x_1, y_2)} = \frac{1}{3}.
\]

So the binary objective does not give consistent estimation of the conditional distribution.

### 4.4 Asymptotic Normality and Statistical Efficiency

Noise Contrastive Estimation significantly reduces the computational complexity, especially when the label space |\(\mathcal{Y}\)| is large. It is natural to ask: does such scalability come at a cost? Classical likelihood theory tells us, under mild conditions, the maximum likelihood estimator (MLE) has nice properties like asymptotic normality and Fisher efficiency. More specifically, as the sample size goes to infinity, the distribution of the MLE will converge to a multivariate normal distribution, and the mean square error of the MLE will achieve the Cramer-Rao lower bound (Ferguson, 1996).

We have shown the consistency of the NCE estimators in Theorem 4.2 and Theorem 4.4. In this part of the paper, we derive their asymptotic distribution and quantify their statistical efficiency. To this end, we restrict ourselves to the case where \(\theta^*\) is identifiable (i.e. Assumptions 4.1 or 4.4 hold) and the scoring function \(s(x; y; \theta)\) satisfies the following smoothness condition:

**Assumption 4.6 (Smoothness).** The scoring function \(s(x; y; \theta)\) is twice continuous differentiable w.r.t. \(\theta\) for all \((x, y) \in \mathcal{X} \times \mathcal{Y}\).

We first introduce the following maximum-likelihood estimator.

\[
\hat{\theta}^{MLE} = \arg\min_{\theta} L_B n(\theta)
\]

\[
:= \arg\min_{\theta} \sum_{i=1}^{n} \log \left( \frac{\exp(s(x^{(i)}; y^{(i)}; \theta))}{\sum_{y \in \mathcal{Y}} \exp(s(x^{(i)}; y; \theta))} \right).
\]

Define the matrix

\[
\mathcal{I}_{\theta^*} = E_X \left[ \text{Var}_{Y|X \sim x} \left[ \nabla_{\theta} s(x, y; \theta^*) \right] \right].
\]

As shown below, \(\mathcal{I}_{\theta^*}\) is essentially the Fisher information matrix under the conditional model.

**Theorem 4.5** Under Assumption 2.1, 4.1, 4.3, and 4.6, if \(\mathcal{I}_{\theta^*}\) is non-singular, as \(n \to \infty\)

\[
\sqrt{n}(\hat{\theta}^{MLE} - \theta^*) \Rightarrow \mathcal{N}(0, \mathcal{I}_{\theta^*}^{-1}).
\]

For any given estimator \(\hat{\theta}\), define the scaled asymptotic mean square error by

\[
\text{MSE}_\infty(\hat{\theta}) = \lim_{n \to \infty} E \left[ \frac{1}{d} \left( \sqrt{n}(\hat{\theta} - \theta^*) \right)^2 \right],
\]

where \(d\) is the dimension of the parameter \(\theta^*\). Theorem 4.5 implies that,

\[
\text{MSE}_\infty(\hat{\theta}^{MLE}) = \text{Tr}(\mathcal{I}_{\theta^*}^{-1})/d.
\]

where \(\text{Tr}(\cdot)\) denotes the trace of a matrix. According to classical MLE theory (Ferguson, 1996), under certain regularity conditions, this is the best achievable mean square error. So the next question to answer is: can these NCE estimators approach this limit?
Assumption 4.7 There exist positive constants $c,C$ such that $\sigma_{\min}(I_{g'}) \geq c$ and
\[
\max_{(x,y) \in \mathcal{X} \times \mathcal{Y}} \left\{ |s(x, y; \theta^*)|, \|\nabla_{\theta} s(x, y; \theta^*)\|, \|\nabla^2_{\theta} s(x, y; \theta^*)\| \right\} \leq C.
\]
where $\sigma_{\min}(\cdot)$ denotes the smallest singular value.

Theorem 4.6 (Ranking) Under Assumption 2.1, 4.1, 4.3, 4.6, 4.7, there exists an integer $K_0$ such that for all $K \geq K_0$, as $n \to \infty$
\[
\sqrt{n} \left( \hat{\theta}_R - \theta^* \right) \Rightarrow N(0, I^{-1}_{R,K}), \tag{9}
\]
for some matrix $I_{R,K}$. There exists a constant $C$ such that for all $K \geq K_0$,
\[
|\text{MSE}_\infty(\hat{\theta}_R) - \text{MSE}_\infty(\hat{\theta}_{\text{MLE}})| \leq C/\sqrt{K}
\]
\[
\|I^{-1}_{R,K} - I^{-1}_{g'}\| \leq C/\sqrt{K}
\]

Theorem 4.7 (Binary) Under Assumption 2.2, 4.4, 4.5, 4.6, 4.7, there exists an integer $K_0$ such that, for any $K \geq K_0$, as $n \to \infty$
\[
\sqrt{n} \left( \hat{\theta}_B - \theta^* \right) \Rightarrow N(0, I^{-1}_{B,K}), \tag{10}
\]
for some matrix $I_{B,K}$. There exists a constant $C$ such that for all $K \geq K_0$,
\[
|\text{MSE}_\infty(\hat{\theta}_B) - \text{MSE}_\infty(\hat{\theta}_{\text{MLE}})| \leq C/K
\]
\[
\|I^{-1}_{B,K} - I^{-1}_{g'}\| \leq C/K.
\]

Remark 4.2 Theorem 4.6 and 4.7 reveal that under respective model assumptions, for any given $K \geq K_0$ both NCE estimators are asymptotically normal and $\sqrt{n}$-consistent. Moreover, both NCE estimators approach Fisher efficiency (statistical optimality) as $K$ grows.

5 Experiments

5.1 Simulations

Suppose we have a feature space $\mathcal{X} \subset \mathbb{R}^d$ with $|\mathcal{X}| = m_x$, label space $\mathcal{Y} = \{1, \cdots, m_y\}$, and parameter $\theta = (\theta_1, \cdots, \theta_{m_y}) \in \mathbb{R}^{m_x \times d}$. Then for any given sample size $n$, we can generate observations $(x^{(i)}, y^{(i)})$ by first sampling $x^{(i)}$ uniformly from $\mathcal{X}$ and then sampling $y^{(i)} \in \mathcal{Y}$ by the conditional model
\[
p(y|x; \theta) = \exp(x' \theta_y)/\sum_{y=1}^{m_y} \exp(x' \theta_y).
\]
We first consider the estimation of $\theta$ by MLE and NCE-ranking. We fix $d = 4$, $m_x = 200$, $m_y = 100$ and generate $\mathcal{X}$ and the parameter $\theta$ from separate mixtures of Gaussians. We try different configurations of $(n, K)$ and report the KL divergence between the estimated distribution and true distribution, as summarized in the left panel of figure 2.

The observations are:

- The NCE estimators are consistent for any fixed $K$. For a fixed sample size, the NCE estimators become comparable to MLE as $K$ increases.
- The larger the sample size, the less sensitive are the NCE estimators to $K$. A very small value of $K$ seems to suffice for large sample size.

Apparently, under the parametrization above, the model is not self-normalized. To use NCE-binary, we add an extra $x$-dependent bias parameter $b_x$ to the score function (i.e. $s(x, y; \theta) = x' \theta + b_x$) to make the model self-normalized or else the algorithm will not be consistent. Similar patterns to figure 2 are observed when varying sample size and $K$ (see Section A.1 of the supplementary material). However this makes NCE-binary not directly comparable to NCE-ranking/MLE since its performance will be compromised by estimating extra parameters and the number of extra parameters depends on the richness of the feature space $\mathcal{X}$. To make this clear, we fix $n = 16000$, $d = 4$, $m_y = 100$, $K = 32$ and experiment with $m_x = 100, 200, 300, 400$. The results are summarized on the right panel of figure 2. As $|\mathcal{X}|$ increases, the KL divergence will grow while the performance of NCE-ranking/MLE is independent of $|\mathcal{X}|$. Without the $x$-dependent bias term for NCE-binary, the KL divergence will be much higher due to lack of consistency (0.19, 0.21, 0.24, 0.26 respectively).

5.2 Language Modeling

We evaluate the performance of the two NCE algorithms on a language modeling problem, using the Penn Treebank (PTB) dataset (Marcus et al., 1993). We choose (Zaremba et al., 2014) as the benchmark where the conditional distribution is modeled by two-layer LSTMs and the parameters are estimated by MLE (note that the current state-of-the-art is (Yang et al., 2018)). Zaremba et al. (2014) implemented 3 model configurations: “Small”, “Medium” and “Large”, which have 200, 650 and 1500 units per layer respectively. We follow their setup (model size, unrolled steps, dropout ratio, etc) but train the model by maximiz-
Table 1: Perplexity on the test set of Penn Treebank. We show performance for the ranking v.s. binary loss algorithms, with different values for $K$, and with/without regularization.

| $K$ | 200 | 400 | 800 | 1600 |
|-----|-----|-----|-----|------|
| NCE Ranking | 113.8 | 112.9 | 111.9 | 110.6 |
| NCE Binary | 106.8 | 105.6 | 105.3 | 104.8 |
| MLE Small | 111.5 | 82.7 | 78.4 |
| MLE Medium | 83.2 | 82.1 | 79.3 | 76.0 |
| MLE Large | 82.3 | 81.5 | 77.9 | 75.6 |
| MLE Ranking | 81.4 | 81.6 | 77.8 | 75.7 |
| MLE Binary | 81.7 | 81.5 | 77.5 | 75.9 |
| reg-MLE | 105.4 | 105.6 | 104.8 |
| reg-Ranking ($K = 1600$) | 105.4 | 79.9 | 77.0 |
| reg-Binary ($K = 1600$) | 79.8 | 75.0 |

The results on the test set are summarized in Table 1. Similar patterns are observed on the validation set (see Section A.2 of the supplementary material). As shown in the table, the performance of NCE-ranking and NCE-binary improves as the number of negative examples increases, and finally outperforms the MLE.

An interesting observation is, without regularization, the binary classification approach outperforms both ranking and MLE. This suggests the model space (two-layer LSTMs) is rich enough as to approximately incorporate the $x$-dependent partition function $Z(\theta; x)$, thus making the model approximately self-normalized. This motivates us to modify the ranking and MLE objectives by adding the following regularization term:

$$\alpha \sum_{i=1}^{n} \log \left( \frac{1}{m} \sum_{j=1}^{m} \exp \left( \bar{s}(x(i), \tilde{y}^{(i,j)}; \theta) \right) \right)^2$$

$$\approx \alpha \mathbb{E}_X \left[ \log Z(x; \theta)^2 \right],$$

where $\tilde{y}^{(i,j)}, 1 \leq j \leq m$ are sampled from the noise distribution $p_N(\cdot)$. This regularization term promotes a constant partition function, that is $Z(x; \theta) \approx 1$ for all $x \in X$. In our experiments, we fix $m$ to be 1/10 of the vocabulary size, $K = 1600$ and tune the regularization parameter $\alpha$. As shown in the last three rows of the table, regularization significantly improves the performance of both the ranking approach and the MLE.

6 Conclusions

In this paper we have analyzed binary and ranking variants of NCE for estimation of conditional models $p(y|x; \theta)$. The ranking-based variant is consistent for a broader class of models than the binary-based algorithm. Both algorithms achieve Fisher efficiency as the number of negative examples increases. Experiments show that both algorithms outperform MLE on a language modeling task. The ranking-based variant of NCE outperforms the binary-based variant once a regularizer is introduced that encourages self-normalization.

Acknowledgments

The authors thank Emily Pitler and Ali Elkahky for many useful conversations about the work, and David Weiss for comments on an earlier draft of the paper.

See table 2 below.

B Proofs

Recall we have the following setup:

- \( \mathcal{X}, \mathcal{Y} \) are finite sets
- \( p_X(x), p_Y(y), p_N(y) > 0, \forall x \in \mathcal{X}, y \in \mathcal{Y} \)

We present the proofs for ranking loss and binary classification loss separately, in the following two subsections.

The following fact will be frequently used in the consistency proof.

Lemma B.1 Define the \( K \)-simplex by

\[
\mathcal{D}_K = \left\{ x | x \in \mathbb{R}^{K+1}_+, \sum_{i=0}^{K} x_i = 1 \right\}.
\]

Then for any \( p \in \mathcal{D}_K \),

\[
p = \arg \max_{q \in \mathcal{D}_K} \sum_{i=0}^{K} q_i \log p_i.
\]

B.1 Proofs for Ranking Loss

To simplify notations, we use \( y_{0:K} \) to represent the vector \( (y_0, \ldots, y_K) \) and \( y^{(i:0:K)} \) to represent \( (y^{(i,0)}, \ldots, y^{(i,K)}) \) where we define \( y^{(i,0)} := y_i \).

For any tuple \((x, y_{0:K})\) and parameter \( \theta \), we define

\[
q(i|x, y_{0:K}; \theta) = \frac{\exp(s(x, y_i; \theta))}{\sum_{i=0}^{K} \exp(s(x, y_i; \theta))}.
\]

Lemma B.2 Under Assumption 2.1,

\[
q(i|x, y_{0:K}; \theta^*) = \frac{\sum_{j=0}^{K} p_{Y|x}(y_j|x)/p_N(y_j)}{\sum_{j=0}^{K} p_{Y|x}(y_j|x)/p_N(y_j)}
\]

Proof: The lemma follows Assumption 2.1 that

\[
p_{Y|x}(y|x) = \frac{\exp(s(x, y; \theta^*))}{Z(x; \theta^*)}
\]

\[
= \frac{p_N(y) \exp(s(x, y; \theta^*))}{Z(x; \theta^*)}
\]

\( \square \)

Lemma B.3 Define

\[
p(y|x; \theta) = \frac{\exp\{s(x, y; \theta)\}}{\sum_y \exp\{s(x, y; \theta)\}}
\]

For any \( \theta_1, \theta_2 \), the following three statements are equivalent:

1. For all \( x, y \)

\[
p(y|x; \theta_1) = p(y|x; \theta_2)
\]

2. For all \( x, y_{0:k} \) and \( 0 \leq i \leq K \)

\[
q(i|x, y_{0:k}; \theta_1) = q(i|x, y_{0:k}; \theta_2)
\]

3. There exists some function \( c(\cdot) \) such that for all \( x, y \)

\[
s(x, y; \theta_1) - s(x, y; \theta_2) = c(x).
\]

Proof: By Lemma B.2,

\[
q(i|x, y_{0:k}; \theta) = \frac{p(y_i|x; \theta)/p_N(y_i)}{\sum_{i=0}^{K} p(y_i|x; \theta)/p_N(y_i)},
\]

and hence \( (1) \Rightarrow (2) \). To show \( (2) \Rightarrow (3) \), notice that, for any \( x, y, y' \), by setting \( i = 0 \) and \( y_0 = y, y_1 = y_2 \ldots = y_K = y' \), \( q(i|x, y_{0:k}; \theta_1) = q(i|x, y_{0:k}; \theta_2) \) will imply

\[
\frac{\exp(s(x, y; \theta_1))}{\exp(s(x, y; \theta_1)) + K \exp(s(x, y'; \theta_1))} = \frac{\exp(s(x, y; \theta_2))}{\exp(s(x, y; \theta_2)) + K \exp(s(x, y'; \theta_2))},
\]

\( \square \)
|                | Small       | Medium      | Large       |
|----------------|-------------|-------------|-------------|
| MLE            | 116.8       | 86.2        | 82.2        |
| NCE            |             |             |             |
| Ranking        | 121.1       | 87.8        | 84.1        |
| Binary         | 112.1       | 86.3        | 80.8        |
| K = 200        |             |             |             |
| K = 400        | 119.0       | 87.2        | 82.9        |
| K = 800        | 116.8       | 86.4        | 82.3        |
| K = 1600       | 116.5       | 86.3        | 82.0        |
| reg-MLE        | 109.9       | 83.1        | 79.9        |
| K = 1600       | 110.5       | 83.3        | 78.4        |
| reg-Binary     | 109.0       | 86.1        | 79.7        |

Table 2: Perplexity on the validation set. We show performance for the Ranking vs. Binary loss algorithms, with different values for $K$, and with/without regularization.

or equivalently,

$$
\frac{1}{1 + K \exp(\bar{s}(x, y; \theta_1) - \bar{s}(x, y; \theta_1))} = \frac{1}{1 + K \exp(\bar{s}(x, y; \theta_2) - \bar{s}(x, y; \theta_2))}.
$$

Then it follows that,

$$
\bar{s}(x, y'; \theta_1) - \bar{s}(x, y; \theta_1) = \bar{s}(x, y'; \theta_2) - \bar{s}(x, y'; \theta_2),
$$

and therefore,

$$
s(x, y; \theta_1) - s(x, y; \theta_2) = s(x, y'; \theta_1) - s(x, y'; \theta_2).
$$

So $s(x, y; \theta_1) - s(x, y; \theta_2)$ only depends on $x$. Finally, we show $(3) \Rightarrow (1)$. If $(3)$ holds, for all $x, y, y'$

$$
s(x, y; \theta_1) - s(x, y; \theta_2) = s(x, y'; \theta_1) - s(x, y'; \theta_2),
$$

which implies

$$
s(x, y; \theta_1) - s(x, y'; \theta_1) = s(x, y; \theta_2) - s(x, y'; \theta_2).
$$

We then have

$$
p(y|x; \theta_1) = \frac{\exp(s(x, y; \theta_1))}{\sum_{y'} \exp(s(x, y'; \theta_1))} = \frac{1}{\sum_{y'} \exp(s(x, y'; \theta_1) - s(x, y; \theta_1))} = \frac{1}{\sum_{y'} \exp(s(x, y'; \theta_2) - s(x, y; \theta_2))} = p(y|x; \theta_2).
$$

\[\square\]

**B.1.1 Proof of Theorem 4.1**

If we define

$$
g_i(\theta; x, y; 0:K) = p_{X|Y}(x, y_i) \prod_{j \neq i} p_N(y_j) \log q(i|x, y; \theta)
$$

then for any $i \in \{0 \ldots K\}$, we have

$$
L^\infty_R(\theta) = \sum_x \sum_{y, 0:K} g_i(x, y; \theta)
$$

It follows that

$$
L^\infty_R(\theta) = \frac{1}{K + 1} \sum_{i=0}^K \sum_x \sum_{y, 0:K} g_i(x, y; \theta) = \frac{1}{K + 1} \sum_{x} \sum_{y, 0:K} \sum_{i=0}^K f(\theta; x, y; 0:K)
$$

where

$$
f(\theta; x, y; 0:K) = \sum_{i=0}^K g_i(x, y; \theta)
$$

$$
= \sum_{i=0}^K p_{X,Y}(x, y_i) \prod_{j \neq i} p_N(y_j) \log q(i|x, y; \theta)
$$

$$
= \left( \sum_{i=0}^K p_{X,Y}(x, y_i) \prod_{j \neq i} p_N(y_j) \right) \times \sum_{i=0}^K \frac{p_{X,Y}(x, y_i) \prod_{j \neq i} p_N(y_j)}{\sum_{i=0}^K p_{X,Y}(x, y_i) \prod_{j \neq i} p_N(y_j)} \log q(i|x, y; \theta)
$$

$$
= \left( \sum_{i=0}^K p_{X,Y}(x, y_i) \prod_{j \neq i} p_N(y_j) \right) \times \sum_{i=0}^K \sum_{j=0}^K \frac{p_{Y|X}(y_j|x) p_N(y_j)}{p_N(y_j)} \log q(i|x, y; \theta).
$$
Next note that $\sum_{i=0}^{K} q(i|x, y_{0}; \theta) = 1$, hence by Lemmas B.1 and B.2, $\theta^* \in \arg \max_{\theta} g(\theta; x, y_{0}; K)$ for all $x, y_{0}; K$, hence $\theta^* \in \arg \max_{\theta} L^\infty_R(\theta)$.

It follows that for any $\hat{\theta} \in \arg \max_{\theta} L^\infty_R(\theta)$, $\hat{\theta}$ must be in $\arg \max_{\theta} g(\theta; x, y_{0}; K)$ for all $x, y_{0}; K$, from which it follows that

$$q(i|x, y_{0}; \hat{\theta}) = q(i|x, y_{0}; \theta^*)$$

for all $x, y_{0}; i$. Then by Lemma B.3, for all $x, y$

$$p(y|x; \hat{\theta}) = p(y|x; \theta^*) = p_{Y|X}(y|x).$$

This proves the first part of the theorem. To prove the second part, for any $\hat{\theta} \in \Theta^*_R$, by the first part of this theorem, for all $x, y$

$$p(y|x; \hat{\theta}) = p(y|x; \theta^*) = p_{Y|X}(y|x).$$

It follows from Lemma B.3 that there exists function $c(x)$ such that for all $x, y$

$$s(x, y; \hat{\theta}) - s(x, y; \theta^*) = c(x).$$

If Assumption 4.1 holds, $\theta = \theta^*$, that is $\Theta^*_R$ is a singleton. On the other hand, if there exists function $c(x)$ and parameter $\theta$ such that for all $x, y$

$$s(x, y; \theta) - s(x, y; \theta^*) = c(x),$$

then by Lemma B.3, for all $x, y$

$$p(y|x; \theta) = p(y|x; \theta^*) = p_{Y|X}(y|x).$$

So $\theta \in \Theta^*_R$. If $\Theta^*_R$ is a singleton, it must be the case that $\hat{\theta} = \theta^*$. This proves the second part of the theorem.

\[ \Box \]

B.1.2 Proof of Theorem 4.2

Under the assumptions in Theorem 4.2, by classical large sample theory (e.g. Theorem 16(a) in (Ferguson, 1996)), for any compact set $\mathcal{K} \subset \Theta$,

$$\mathbb{P} \left\{ \lim_{n \to \infty} \sup_{\theta \in \mathcal{K}} |L^\infty_R(\theta) - L^\infty_R(\theta^*)| = 0 \right\} = 1$$

(11)

Since $|L^\infty_R(\theta) - L^\infty_R(\theta^*)| \geq L^\infty_R(\theta) - L^\infty_R(\theta^*)$,

$$\mathbb{P} \left\{ \lim_{n \to \infty} \sup_{\theta \in \mathcal{K}} (L^\infty_R(\theta) - L^\infty_R(\theta^*)) \leq 0 \right\} = 1.$$  

(12)

For any $\hat{\theta}^*_\mathcal{K} \in \arg \max_{\theta \in \mathcal{K}} L^\infty_R(\theta)$,

$$\sup_{\theta \in \mathcal{K}} (L^\infty_R(\theta) - L^\infty_R(\hat{\theta}^*_\mathcal{K})) \geq L^\infty_R(\hat{\theta}^*_\mathcal{K}) - L^\infty_R(\hat{\theta}^*_\mathcal{K})$$

$$\geq \sup_{\theta \in \mathcal{K}} (L^\infty_R(\hat{\theta}^*_\mathcal{K}) - L^\infty_R(\theta))$$

$$= \sup_{\theta \in \mathcal{K}} L^\infty_R(\theta) - \sup_{\theta \in \mathcal{K}} L^\infty_R(\theta).$$

Combining this inequality and (12) yields

$$\mathbb{P} \left\{ \lim_{n \to \infty} \sup_{\theta \in \mathcal{K}} L^\infty_R(\theta) \leq \sup_{\theta \in \mathcal{K}} L^\infty_R(\theta) \right\} = 1.$$  

(13)

Recall that

$$\Theta^*_R = \left\{ \hat{\theta} \mid \hat{\theta} \in \arg \max_{\theta \in \Theta} L^\infty_R(\theta) \right\}.$$

For any $\rho > 0$, define

$$\Theta_\rho = \left\{ \theta \mid \theta \in \Theta, \ \arg \min_{\theta \in \Theta_R} \|\theta - \theta^*\| \geq \rho \right\}.$$

By Assumption 4.2, $L^\infty_R(\theta)$ is a continuous function of $\theta$ and therefore,

$$\delta_\rho \triangleq \sup_{\theta \in \Theta_\rho} L^\infty_R(\theta) < \delta \triangleq \sup_{\theta \in \Theta} L^\infty_R(\theta).$$

Apply the uniform convergence results in equation (13) with $\mathcal{K} = \Theta_\rho$, with probability 1,

$$\lim_{n \to \infty} \sup_{\theta \in \Theta_\rho} L^\infty_R(\theta) \leq \delta_\rho < \delta.$$  

(14)

On the other hand, substitute $|L^\infty_R(\theta) - L^\infty_R(\theta^*)| \geq L^\infty_R(\theta^*) - L^\infty_R(\theta)$ into (11), with the same arguments as used to obtain (13), one could also show that, for any compact set $\mathcal{K} \subset \Theta$,

$$\mathbb{P} \left\{ \lim_{n \to \infty} \sup_{\theta \in \mathcal{K}} L^\infty_R(\theta) \geq \sup_{\theta \in \mathcal{K}} L^\infty_R(\theta) \right\} = 1.$$  

Let $\mathcal{K} = \Theta$, by definition,

$$\mathbb{P} \left\{ \lim_{n \to \infty} L^\infty_R(\hat{\theta}_R) \geq \delta \right\} = 1.$$  

(15)

Combine equations (14), (15), there exists integer $N$ such that

$$\mathbb{P} \left\{ \hat{\theta}_R \notin \Theta_\rho, \text{ for all } n \geq N \right\} = 1.$$  

Since this holds for any $\rho > 0$,

$$\mathbb{P} \left\{ \lim_{n \to \infty} \min_{\theta^* \in \Theta_R} \|\hat{\theta}^*_R - \theta^*\| = 0 \right\} = 1.$$  

(16)
Define the mapping \( g \) from the parameter space \( \Theta \) to the function space on \( \mathcal{X} \times \mathcal{Y} \) by \( g(\theta) = p(\cdot, \cdot; \theta) \) where

\[
p(x, y; \theta) = \exp(s(x, y; \theta))/Z(x; \theta),
\]
and \( Z(x; \theta) = \sum_{y \in \mathcal{Y}} \exp(s(x, y; \theta)) \). By Theorem 4.1,

\[
\Theta^*_R = \{ \theta \mid g(\theta) = p_{\mathcal{Y}|X}, \theta \in \Theta \}.
\]
(17)

Further by Assumption 4.2, \( g(\theta) \) is a continuous function of \( \theta \) under the metric \( d(\cdot, \cdot) \). Since \( \Theta \) is compact set, \( g(\theta) \) is uniform continuous. By uniform continuity, for any \( \varepsilon > 0 \), there exists \( \Delta \) such that, for any \( \theta_1, \theta_2 \) satisfying \( \|\theta_1 - \theta_2\| \leq \Delta \),

\[
d(g(\theta_1), g(\theta_2)) \leq \varepsilon.
\]

Hence, equation (16) implies

\[
P\left\{ \lim_{n \to \infty} d\left( \hat{p}_n, p_{\mathcal{Y}|X} \right) = 0 \right\} = 1.
\]

When assumption 4.1 holds, by Theorem 4.1, \( \Theta^* = \{ \theta^* \} \) is a singleton and equation (16) is reduced to

\[
P\left\{ \lim_{n \to \infty} \hat{\theta}_n = \theta^* \right\} = 1.
\]

### B.1.3 Proof of Theorem 4.6

Since we have defined \( y^{(i,0)} := y^{(i)} \), the objective function \( L_R^n(\theta) \) can be written as the average of the following I.I.D. random variables \( L_R^{(i)}(\theta), 1 \leq i \leq n \):

\[
L_R^n(\theta) = \frac{1}{n} \sum_{i=1}^{n} \log \left( \frac{\exp(s(x^{(i)}, y^{(i,0)}; \theta))}{\sum_{j=0}^{K} \exp(s(x^{(i)}, y^{(i,j)}; \theta))} \right)
\]

\[
= \frac{1}{n} \sum_{i=1}^{n} L_R^{(i)}(\theta).
\]

Define

\[
L_R(\theta) = \log \left( \frac{\exp(s(x, y_0; \theta))}{\sum_{j=0}^{K} \exp(s(x, y_j; \theta))} \right)
\]

where \( (x, y_{0:K}) \sim p_{\mathcal{X,Y}}(x, y_0) \prod_{j=1}^{K} p_N(y_j) \).

Then we have

\[
(x^{(i)}, y^{(i,0:K)}) = d (x, y_0, \cdots, y_K)
\]

\[
L_R^{(i)}(\theta) = d L_R(\theta)
\]

for \( 1 \leq i \leq n \), where \( =d \) represents equal in distribution.

### Lemma B.4

For any \( g(x, y_0, \cdots, y_K) : \mathcal{X} \times \mathcal{Y} \to \mathbb{R} \) satisfying

\[
g(x, y_0, \cdots, y_K) = g(x, y_{\pi(0)}, \cdots, y_{\pi(K)}),
\]

where \( \pi \) is any permutation on \( \{0, 1, \cdots, K\} \), the following equality holds for any function \( f(\cdot, \cdot) : \mathcal{X} \times \mathcal{Y} \to \mathbb{R}^l \) where \( l \in \mathbb{N}_+ \).

\[
E \left[ \sum_{j=0}^{K} q(j|x, y_{0:K}; \theta^*) g(x, y_0, \cdots, y_K) \right] = E \left[ g(x, y_0, \cdots, y_K) f(x, y_0) \right],
\]

where \( (x, y_{0:K}) \sim p_{\mathcal{X,Y}}(x, y_0) \prod_{j=1}^{K} p_N(y_j) \).

**Proof:** We use \( g(x, y_{0:K}) \) to represent \( g(x, y_0, \cdots, y_K) \). By definition,

\[
E \left[ \sum_{j=0}^{K} q(j|x, y_{0:K}; \theta^*) g(x, y_{0:K}) \right]
\]

\[
= \sum_{x, y_{0:K}} p_{\mathcal{X,Y}}(x, y_0) \prod_{j=1}^{K} p_N(y_j) \times
\]

\[
\sum_{j=0}^{K} q(j|x, y_{0:K}; \theta^*) g(x, y_{0:K})
\]

\[
= \sum_{x, y_{0:K}} p_{\mathcal{X}}(x) \prod_{j=0}^{K} p_N(y_j) \frac{p_{\mathcal{Y}|X}(y_0|x; \theta)}{p_N(y_0)} \times
\]

\[
\sum_{j=0}^{K} q(j|x, y_{0:K}; \theta^*) g(x, y_{0:K})
\]

By symmetry,

\[
E \left[ \sum_{j=0}^{K} q(j|x, y_{0:K}; \theta^*) g(x, y_{0:K}) \right]
\]

\[
= \sum_{x, y_{0:K}} p_{\mathcal{X}}(x) \prod_{j=0}^{K} p_N(y_j) \sum_{l=0}^{K} \frac{p_{\mathcal{Y}|X}(y_l|x; \theta)}{p_N(y_l)} \times
\]

\[
\sum_{j=0}^{K} q(j|x, y_{0:K}; \theta^*) g(x, y_{0:K})
\]

Plug in the definition of \( q(j|x, y_{0:K}; \theta^*) \) and by
symmetry,
\[
\mathbb{E} \left[ \sum_{j=0}^{K} q(j|x, y_0; \theta^*) g(x, y_0) \right] 
\]
\[
= \sum_{x, y_0; K} \left\{ p_X(x) \prod_{j=0}^{K} p_N(y_j) \right\} g(x, y_0) 
\]
\[
= \sum_{x, y_0; K} p_X(x) \prod_{j=0}^{K} p_N(y_j) \left( \sum_{i=0}^{K} p_Y|X(i|x) \right) 
\]
\[
\times g(x, y_0) f(x, y_0) 
\]
\[
= \mathbb{E} [g(x, y_0) f(x, y_0)] 
\]
Also notice that,
\[
\nabla_{\theta} L_R(\theta^*) = \nabla_{\theta} \bar{s}(x, y_0; \theta^*) - \sum_{j=0}^{K} q(j|x, y_0; \theta^*) \nabla_{\theta} \bar{s}(x, y_j; \theta^*). \quad (20)
\]
By Lemma B.4,
\[
\mathbb{E}[L_R(\theta^*)] = 0.
\]
Hence \(\mathbb{E}[L_R^n(\theta^*)] = 0\) and by Central Limit Theorem,
\[
\sqrt{n} \nabla_{\theta} L_R^n(\theta^*) \to \mathcal{N}(0, \text{Var} [\nabla_{\theta} L_R(\theta^*)]). \quad (21)
\]
Combining these facts together,
\[
\sqrt{n} \left( \hat{\theta}_R - \theta^* \right) \to \mathcal{N}(0, V_R)
\]

\[\square\]

**Lemma B.5** Under the assumptions in Theorem 4.6, as \(n \to \infty\)
\[
\sqrt{n} \left( \hat{\theta}_R - \theta^* \right) \to \mathcal{N}(0, V_R)
\]
where \(V_R = \mathbb{E} \left[ \nabla_{\theta}^2 L_R(\theta^*) \right]^{-1} \text{Var} \left[ \nabla_{\theta} L_R(\theta^*) \right] \mathbb{E} \left[ \nabla_{\theta}^2 L_R(\theta^*) \right]^{-1}
\]

**Proof:** By the Mean-Value Theorem,
\[
\nabla_{\theta} L_R^n(\hat{\theta}_R) = \nabla_{\theta} L_R^n(\theta^*) + 
\left[ \int_0^1 \nabla_{\theta}^2 L_R^n \left( \theta^* + t(\hat{\theta}_R - \theta^*) \right) dt \right] (\hat{\theta}_R - \theta^*).
\]
Notice that \(\hat{\theta}_R\) is the maximizer of \(L_R^n(\theta)\). By Theorem 4.2, \(\theta^*\) is strongly consistent. Since \(\theta^*\) is in the interior of a compact set \(\Theta\), there exists integer \(N\) such that for all \(n > N\) with probability 1, \(\hat{\theta}_R\) is also in the interior of \(\Theta\). So \(\nabla_{\theta} L_R^n(\hat{\theta}_R) = 0\) and therefore,
\[
\hat{\theta}_R - \theta^* = - \left[ \int_0^1 \nabla_{\theta}^2 L_R^n \left( \theta^* + t(\hat{\theta}_R - \theta^*) \right) dt \right]^{-1} 
\times \nabla_{\theta} L_R^n(\theta^*)
\]
On the one hand, by Strong Law of Large Numbers, for any \(\theta\), almost surely,
\[
\nabla_{\theta}^2 L_R^n(\theta) \to \mathbb{E} [\nabla_{\theta}^2 L_R(\theta)].
\]
On the other hand, by Theorem 4.2, \(\hat{\theta}_R\) is strongly consistent. So for any \(t \in [0, 1]\)
\[
\nabla_{\theta}^2 L_R^n \left( \theta^* + t(\hat{\theta}_R - \theta^*) \right) \to \mathbb{E} [\nabla_{\theta}^2 L_R(\theta^*)].
\]

\[\square\]

**Lemma B.6** Define the matrix \(W_{R,K}\) by
\[
W_{R,K} = \mathbb{E} \left[ \sum_{j=0}^{K} q(j|x, y_0; \theta^*) \nabla_{\theta} \bar{s}(x, y_j; \theta^*) \right] \times \mathbb{E} \left[ \sum_{j=0}^{K} q(j|x, y_0; \theta^*) \nabla_{\theta} \bar{s}(x, y_j; \theta^*) \right]^\top,
\]
where the expectation is w.r.t. \((x, y_0, \cdots, y_K) \sim p_{X,Y}(x, y_0) \prod_{j=1}^{K} p_N(y_j).

**Proof:** This follows directly from Lemma B.4.

\[\square\]

**Lemma B.7**
\[
\mathbb{E} [\nabla_{\theta}^2 L_R(\theta^*)] = \text{Var} [\nabla_{\theta} L_R(\theta^*)]
\]
\[
= \mathbb{E} [\nabla_{\theta} \bar{s}(x, \theta^*) \nabla_{\theta} \bar{s}(x, y; \theta^*)^\top] - W_{R,K}
\]
Proof: Define the shorthand, 
\[ q_j = q(j|x, y_0; K; \theta^*). \]
Notice that,
\[ \nabla_{\theta} L_R(\theta^*) = \nabla_{\theta} \bar{s}(x, y_0; \theta^*) - \sum_{j=0}^{K} q_j \nabla_{\theta} \bar{s}(x, y_j; \theta^*). \]
We then have
\[ \nabla_{\theta}^2 L_R(\theta^*) = \nabla_{\theta}^2 \bar{s}(x, y_0; \theta^*) - \sum_{j=0}^{K} q_j \nabla_{\theta} \bar{s}(x, y_j; \theta^*) \nabla_{\theta} \bar{s}(x, y_j; \theta^*)^\top \]
\[ + \left( \sum_{j=0}^{K} q_j \nabla_{\theta} \bar{s}(x, y_j; \theta^*) \right)^\top \]
\[ + I_1 - I_2 - I_3 + I_4 \]
By Lemma B.4,
\[ \mathbb{E}[I_1 - I_2] = 0 \]
\[ \mathbb{E}[I_3] = \mathbb{E}[\nabla_{\theta} \bar{s}(x, y; \theta^*) \nabla_{\theta} \bar{s}(x, y; \theta^*)^\top]. \]
Hence,
\[ \mathbb{E}[\nabla_{\theta}^2 L_R(\theta^*)] = \mathbb{E} \left[ \nabla_{\theta} \bar{s}(x, y, \theta^*) \nabla_{\theta} \bar{s}(x, y, \theta^*)^\top \right] - W_{R,K}. \]
By Lemma B.4, \( \mathbb{E}[L_R(\theta^*)] = 0. \) Therefore,
\[ \text{Var} \left[ \nabla_{\theta} L_R(\theta^*) \right] = \mathbb{E} \left[ \nabla_{\theta} L_R(\theta^*) \nabla_{\theta} L_R(\theta^*)^\top \right]. \]
Observe that,
\[ \nabla_{\theta} L_R(\theta^*) \nabla_{\theta} L_R(\theta^*)^\top = \nabla_{\theta} \bar{s}(x, y_0; \theta^*) \nabla_{\theta} \bar{s}(x, y_0; \theta^*)^\top \]
\[ - \sum_{j=0}^{K} q_j \nabla_{\theta} \bar{s}(x, y_0; \theta^*) \nabla_{\theta} \bar{s}(x, y_j; \theta^*)^\top \]
\[ - \sum_{j=0}^{K} q_j \nabla_{\theta} \bar{s}(x, y_j; \theta^*) \nabla_{\theta} \bar{s}(x, y_0; \theta^*)^\top \]
\[ + \left( \sum_{j=0}^{K} q_j \nabla_{\theta} \bar{s}(x, y_j; \theta^*) \right)^\top \]
\[ + \left( \sum_{j=0}^{K} q_j \nabla_{\theta} \bar{s}(x, y_j; \theta^*) \right)^\top \]
By Lemma B.6,
\[ \text{Var} \left[ \nabla_{\theta} L_R(\theta^*) \right] = \mathbb{E} \left[ \nabla_{\theta} L_R(\theta^*) \nabla_{\theta} L_R(\theta^*)^\top \right] - W_{R,K}. \]

**Lemma B.8** Under Assumption 4.7, there exists constant \( C \) such that
\[ \sup_{(x, y) \in \mathcal{X} \times \mathcal{Y}} \left\{ |\bar{s}(x, y; \theta^*)|, \|\nabla_{\theta} \bar{s}(x, y; \theta^*)\| \right\} \leq C. \]

Proof: By definition,
\[ \bar{s}(x, y; \theta^*) = \nabla_{\theta} s(x, y; \theta^*) + \log p_N(y). \]
Then it follows that,
\[ \nabla_{\theta} \bar{s}(x, y; \theta^*) = \nabla_{\theta} s(x, y; \theta^*), \]
\[ \nabla_{\theta}^2 \bar{s}(x, y; \theta^*) = \nabla_{\theta}^2 s(x, y; \theta^*). \]
Since \( p_N(y) > 0 \) for all \( y \in \mathcal{Y} \) and \( \mathcal{Y} \) is finite, there exists constant \( c \) such that
\[ p_N(y) > c. \]
Therefore,
\[ \sup_{(x, y) \in \mathcal{X} \times \mathcal{Y}} |\bar{s}(x, y; \theta^*)| \]
\[ \leq \sup_{(x, y) \in \mathcal{X} \times \mathcal{Y}} |s(x, y; \theta^*)| + \log(1/c). \]
Then the Lemma follows from Assumption 4.7.

**Lemma B.9** Under the assumptions in Theorem 4.6, there exists an integer \( K_0 \) such that for some constant \( C \) and all \( K \geq K_0 \),
\[ W_{R,K} = \mathbb{E}_X \left[ \left( \mathbb{E}_{Y|x=x} \nabla_{\theta} \bar{s}(x, y; \theta^*) \right) \times \left( \mathbb{E}_{Y|x=x} \nabla_{\theta} \bar{s}(x, y; \theta^*) \right)^\top \right] + \Delta_K \]
and
\[ \|\Delta_K\| \leq C \sqrt{K}. \]

Proof: Define the abbreviation
\[ q_j = q(j|x, y_0; K; \theta^*) \]
and decompose $W_{R,K}$ into two terms,

$$W_{R,K} = \mathbb{E} \left[ \sum_{j=0}^{K} q_j \nabla_{\theta} \bar{s}(x, y_0; \theta^*) \nabla_{\theta} \bar{s}(x, y_j; \theta^*)^\top \right]
= \mathbb{E} \left[ q_0 \nabla_{\theta} \bar{s}(x, y_0; \theta^*) \nabla_{\theta} \bar{s}(x, y_0; \theta^*)^\top \right]
+ \mathbb{E} \left[ \sum_{j=1}^{K} q_j \nabla_{\theta} \bar{s}(x, y_0; \theta^*) \nabla_{\theta} \bar{s}(x, y_j; \theta^*)^\top \right]
:= J_1 + J_2.

By Lemma B.8,

$$||J_1|| \leq \sup_{x,y} \left\| \nabla_{\theta} \bar{s}(x, y; \theta^*) \nabla_{\theta} \bar{s}(x, y; \theta^*)^\top \right\| \times \sup_{x,y} q_0 \times C^2 \times \frac{\exp(C)}{K \exp(-C)} \leq \frac{C_1}{K}$$

By symmetry,

$$J_2 = K \mathbb{E} \left[ q_1 \nabla_{\theta} \bar{s}(x, y_0; \theta^*) \nabla_{\theta} \bar{s}(x, y_1; \theta^*)^\top \right]
\leq \frac{\exp(C)}{K \exp(-C)} \leq \frac{C_1}{K}$$

Substitute in the definition of $q_1$,

$$J_2 = \sum_{x,y_0, K} p_X(x) p_{Y|X}(y_0|x) \prod_{i=1}^{K} p_N(y_i)
\times \frac{\exp(\bar{s}(x, y_1; \theta^*))}{Z(x; \theta^*) - \frac{1}{K} \sum_{i=0}^{K} \exp(\bar{s}(x, y_i; \theta^*))
\times \nabla_{\theta} \bar{s}(x, y_0; \theta^*) \nabla_{\theta} \bar{s}(x, y_1; \theta^*)^\top}
\times \frac{1}{K} \sum_{i=0}^{K} \exp(\bar{s}(x, y_i; \theta^*))
\times \nabla_{\theta} \bar{s}(x, y_0; \theta^*) \nabla_{\theta} \bar{s}(x, y_1; \theta^*)^\top}

Notice that

$$\exp(\bar{s}(x, y_1; \theta^*)) = \exp(s(x, y_1; \theta^*)) / p_X(y_1) = p_{Y|X}(y_1|x) Z(x; \theta^*) / p_N(y_1).$$

Then we can derive

$$J_2 = \sum_{x,y_0, K} p_X(x) p_{Y|X}(y_0|x) p_{Y|X}(y_1|x)
\times \prod_{i=2}^{K} p_N(y_i) \nabla_{\theta} \bar{s}(x, y_0; \theta^*) \nabla_{\theta} \bar{s}(x, y_1; \theta^*)^\top
\times \frac{Z(x; \theta^*)}{\frac{1}{K} \sum_{i=0}^{K} \exp(\bar{s}(x, y_i; \theta^*))
\times \nabla_{\theta} \bar{s}(x, y_0; \theta^*) \nabla_{\theta} \bar{s}(x, y_1; \theta^*)^\top}
\times \frac{\exp(C)}{\exp(-C) \exp(-C) \exp(-C)} \leq C_2.$$
We then have,

\[
\|\delta\| \leq C_2 \sum_{x,y_0,K} p_X(x) \prod_{i=0}^{K} p_N(y_i) \\
\times \left| Z(x; \theta^*) - \frac{1}{K} \sum_{i=1}^{K} \exp \left( \tilde{s}(x, y_i; \theta^*) \right) \right| \\
\leq C_2 E_{p_X(x)} E_{\Pi_{i=1}^{K} p_N(y_i)} \left| Z(x; \theta^*) - \frac{1}{K} \sum_{i=1}^{K} \exp \left( \tilde{s}(x, y_i; \theta^*) \right) \right| + C_2 \exp(C) \\
\leq C_2 E_{p_X(x)} \left( E_{\Pi_{i=1}^{K} p_N(y_i)} \right) \left| Z(x; \theta^*) - \frac{1}{K} \sum_{i=1}^{K} \exp \left( \tilde{s}(x, y_i; \theta^*) \right) \right|^{2} \frac{1}{2} + C_2 \exp(C) \\
\leq C_2 \exp(C) \frac{1}{K} \sum_{i=1}^{K} \exp \left( \tilde{s}(x, y_i; \theta^*) \right)
\]

Notice that for any given \( x \) and \( y_i \sim p_N(y_i) \), \( \exp(\tilde{s}(x, y_i; \theta^*)) \) are I.I.D. random variables with expectation \( Z(x; \theta^*) \). Therefore, by Lemma B.8,

\[
E_{\Pi_{i=1}^{K} p_N(y_i)} \left| Z(x; \theta^*) - \frac{1}{K} \sum_{i=1}^{K} \exp(s(x, y_i; \theta^*)) \right|^{2} \leq \frac{1}{K} \sum_{i=1}^{K} \exp(2s(x, y_i; \theta^*)) \\
\leq \frac{1}{K} \exp(2) \\
\]

and for some constant \( C_3 \),

\[
\|\delta\| \leq C_2 \frac{\exp(C)}{\sqrt{K}} + C_2 \frac{\exp(C)}{K + 1} \leq C_3 \frac{\sqrt{K}}{\sqrt{K}}
\]

Combining these facts together,

\[
W_{R,K} = E_X \left[ \left( \frac{E_{Y|X=x} \nabla \tilde{s}(x, y; \theta^*)}{\nabla \tilde{s}(x, y; \theta^*)} \right) \right] + \Delta_K
\]

where \( \Delta_K = J_1 + \delta \) and for some constant \( C_4 \),

\[
\|\Delta_K\| \leq C_4 \frac{K}{K}
\]

\[]

**Proof of Theorem 4.6.** By Lemma B.5 and B.7,

\[
\sqrt{n}(\hat{\theta}_R - \theta^*) \to N \left( 0, I_{I,R,K}^{-1} \right)
\]

where

\[
I_{I,R,K} = E[\nabla \tilde{s}(x, y; \theta^*) \nabla \tilde{s}(x, y; \theta^*)^T] - W_{R,K}.
\]

Notice that

\[
E \left[ \nabla \tilde{s}(x, y; \theta^*) \nabla \tilde{s}(x, y; \theta^*)^T \right] - \nabla \tilde{s}(x, y; \theta^*)
\]

\[
E_X \left[ \left( E_{Y|X=x} \nabla \tilde{s}(x, y; \theta^*) \right) \right] \nabla \tilde{s}(x, y; \theta^*)^T
\]

\[
E_X \left[ \left( E_{Y|X=x} \nabla \tilde{s}(x, y; \theta^*) \right) \nabla \tilde{s}(x, y; \theta^*) \right] - \nabla \tilde{s}(x, y; \theta^*)^T
\]

\[
E_X \left[ \left( E_{Y|X=x} \nabla \tilde{s}(x, y; \theta^*) \right) \nabla \tilde{s}(x, y; \theta^*) \right] - \nabla \tilde{s}(x, y; \theta^*)^T
\]

\[
E_X \left[ \left( E_{Y|X=x} \nabla \tilde{s}(x, y; \theta^*) \right) \nabla \tilde{s}(x, y; \theta^*) \right] - \nabla \tilde{s}(x, y; \theta^*)^T
\]

where the second last equation follows from the fact that

\[
\nabla \tilde{s}(x, y; \theta) = \nabla \tilde{s}(x, y; \theta)
\]

for all \( x, y, \theta \). So by Lemma B.9,

\[
I_{R,K} = I_{I^*} - \Delta_K.
\]

Since \( I_{I^*} \) is non-singular, there exists positive integer \( K_0 \) such that for any \( K \geq K_0 \), \( \sigma_{\min}(I_{I^*}) \geq 2\|\Delta_K\| \). So \( I_{R,K} \) is positive definite and by Weyl’s inequality,

\[
\sigma_{\min}(I_{R,K}) \geq \sigma_{\min}(I_{I^*}) - \|\Delta_K\| \geq \sigma_{\min}(I_{I^*})/2.
\]

Notice that,

\[
I_{R,K}^{-1} - I_{I^*}^{-1} = I_{I^*}^{-1}(I_{I^*} - I_{R,K})I_{R,K}^{-1}
\]

\[
= I_{I^*}^{-1}\Delta_K I_{R,K}^{-1}
\]

Then we have

\[
\|I_{R,K}^{-1} - I_{I^*}^{-1}\| \leq \|I_{R,K}^{-1}\| \|\Delta_K\| \|I_{R,K}^{-1}\|
\]

\[
\leq \frac{1}{\sigma_{\min}(I_{I^*})} \times \frac{C}{\sqrt{K}} \times \frac{2}{\sigma_{\min}(I_{I^*})}
\]

\[
\leq \frac{2C}{\sigma^2 \sqrt{K}}
\]

Finally, notice that \( \hat{\theta}_R, \hat{\theta}^{\text{MLE}} \) are asymptotically unbiased,

\[
\|\text{MSE}_{\infty}(\hat{\theta}_R) - \text{MSE}_{\infty}(\hat{\theta}^{\text{MLE}})\|
\]

\[
= \text{Tr}(I_{R,K}^{-1} - I_{I^*}^{-1})/d
\]

\[
\leq d\|I_{R,K}^{-1} - I_{I^*}^{-1}\|/d
\]

\[
\leq \frac{2C}{\sigma^2 \sqrt{K}}
\]
B.2 Proofs for Binary Classification Loss

Recall that for any \( x, y \) and parameter \((\theta, \gamma)\), we have defined
\[
g(x, y; \theta, \gamma) = \frac{\exp(s(x, y; \theta) - \gamma)}{\exp(s(x, y; \theta) - \gamma) + K}.
\]

**Lemma B.10** Under Assumption 2.2,
\[
g(x, y; \theta^*, \gamma^*) = \frac{p_{Y|X}(y|x)}{p_{Y|X}(y|x) + K p_N(y)}
\]

**Proof:** Under Assumption 2.2,
\[
p_{Y|X}(y|x) = p_N(y) \exp(s(x, y; \theta^*) - \gamma^*).
\]

Hence
\[
\frac{p_{Y|X}(y|x)}{p_{Y|X}(y|x) + K p_N(y)} = \frac{p_N(y) \exp(s(x, y; \theta^*) - \gamma^*)}{p_N(y) \exp(s(x, y; \theta^*) - \gamma^*) + K p_N(y)} = \frac{\exp(s(x, y; \theta^*) - \gamma^*)}{\exp(s(x, y; \theta^*) - \gamma^*) + K}.
\]

\[\square\]

**Lemma B.11** Define
\[
p(y|x; \theta, \gamma) = \exp\{s(x, y; \theta) - \gamma\}
\]

For any \((\theta_1, \gamma_1), (\theta_2, \gamma_2)\), the following three statements are equivalent:

1. For all \( x, y \),
   \[p(y|x; \theta_1, \gamma_1) = p(y|x; \theta_2, \gamma_2)\]

2. For all \( x, y \),
   \[g(x, y; \theta_1, \gamma_1) = g(x, y; \theta_2, \gamma_2)\]

3. For all \( x, y \),
   \[s(x, y; \theta_1) - \gamma_1 = s(x, y; \theta_2) - \gamma_2.\]

**Proof:** Since \( p_Y(y) > 0 \) for all \( y \in \mathcal{Y} \),
\[
g(x, y; \theta, \gamma) = \frac{p(y|x; \theta, \gamma)}{p(y|x; \theta, \gamma) + K p_N(y)},
\]
and hence (1) \(\Rightarrow\) (2). Observe that,
\[
s(x, y; \theta) - \gamma = \log \left( \frac{g(x, y; \theta, \gamma)}{1 - g(x, y; \theta, \gamma)} \right) + \log(K)
\]
and by definition
\[
s(x, y; \theta) = s(x, y; \theta) + \log p_N(y)
\]
We then have (2) \(\Rightarrow\) (3). Finally, (3) \(\Rightarrow\) (1) is obtained by plugging in the definition of \(g(x, y; \theta, \gamma)\). \(\square\)

B.2.1 Proof of Theorem 4.3

Notice that \( L_{\theta, \gamma}^\infty(x, y) = \sum_{x,y} f(x, y; \theta, \gamma) \), where
\[
f(x, y; \theta, \gamma) = \left\{ \begin{array}{ll} p_{X,Y}(x,y) & \log(g(x,y;\theta,\gamma)) \\
Kp_{X}(x)p_{N}(y) & \log(1-g(x,y;\theta,\gamma)) \\
\end{array} \right.
\]

By Lemma B.1 and B.10, \((\theta^*, \gamma^*) \in \arg \max f(\theta, \gamma; x, y)\) for all \(x, y\). Then for any \((\bar{\theta}, \bar{\gamma}) \in \arg \max L_{\theta, \gamma}^\infty(\theta, \gamma)\), it must be the case that \((\bar{\theta}, \bar{\gamma})\) maximizes \(f(\theta, \gamma; x, y)\) for all \(x, y\) simultaneously. It follows from Lemma B.1 that
\[
\frac{\exp(s(x, y; \bar{\theta}) - \bar{\gamma})}{\exp(s(x, y; \theta) - \gamma) + K} = \frac{p_Y(y|x)}{p_{Y|X}(y|x) + K p_N(y)} = \frac{\exp(s(x, y; \theta^*) - \gamma^*)}{\exp(s(x, y; \theta^*) - \gamma^*) + K}.
\]

By Lemma B.11, this is equivalent to
\[
s(x, y; \bar{\theta}) - \bar{\gamma} = s(x, y; \theta^*) - \gamma^* \tag{22}
\]
which implies,
\[
s(x, y; \bar{\theta}) - \bar{\gamma} = s(x, y; \theta^*) - \gamma^* \tag{23}
\]
and therefore
\[
p(y|x; \bar{\theta}, \bar{\gamma}) = p(y|x; \theta^*, \gamma^*),
\]
which proves the first part of the theorem. Under Assumption 4.4, equation (23) implies \((\bar{\theta}, \bar{\gamma}) = (\theta^*, \gamma^*)\), that is \(\Omega^\infty_{\theta, \gamma}\) is a singleton. On the other hand, if there exists constant \(c\) and parameter \(\bar{\theta}\) such that for all \(x, y\)
\[
s(x, y; \bar{\theta}) - s(x, y; \theta^*) = c.
\]

We then have
\[
\bar{\gamma} = \log \left( \sum_{x,y} p_{X}(x) \exp(s(x, y; \theta^*) + c) \right)
\]
and
\[
s(x, y; \bar{\theta}) - \bar{\gamma} = s(x, y; \theta^*) - \gamma^*.
\]
It follows from Lemma B.1 and B.11 that \((\theta, \gamma) \in \arg \max L_{Rn}^i(\theta, \gamma)\). So if \(\Omega_{Bn}\) is a singleton, it must be the case that \(\theta = \theta^*, \gamma = \gamma^*\). This proves the second part of the theorem.

B.2.2 Proof of Theorem 4.4
The proof is very similar to the proof of Theorem 4.2 and we leave out the details.

B.2.3 Proof of Theorem 4.5
The proof is very similar to the proof of Theorem 4.6 and the proof of Theorem 4.7. We leave out the details.

B.2.4 Proof of Theorem 4.7
Define \(\beta = (\theta, \gamma), \hat{\beta} = (\hat{\theta}_B, \hat{\gamma}_B), \beta^* = (\theta^*, \gamma^*)\) and \(\bar{s}(x, y; \beta) = s(x, y; \theta) - \gamma - \log K\).

Then the objective function \(L_{Rn}^i(\theta, \gamma)\) could be written as the average of \(n\) I.I.D. random variables \(L_B^i(\beta), 1 \leq i \leq n\).

\[
L_{Rn}^i(\theta, \gamma) = \frac{1}{n} \sum_{i=1}^{n} \left\{ \log \left( \frac{\exp(\bar{s}(x^{(i)}, y^{(i)}, \beta))}{1 + \exp(\bar{s}(x^{(i)}, y^{(i)}, \beta))} \right) + \sum_{j=1}^{K} \log \left( \frac{1}{1 + \exp(\bar{s}(x^{(i)}, y^{(i)}, \beta))} \right) \right\} \\
= \frac{1}{n} \sum_{i=1}^{n} \left\{ \log \sigma(\bar{s}(x^{(i)}, y^{(i)}; \beta)) + \sum_{j=1}^{K} \log(1 - \sigma(\bar{s}(x^{(i)}, y^{(i)}, \beta))) \right\} \\
:= \frac{1}{n} \sum_{i=1}^{n} L_B^i(\beta). \tag{24}
\]

Define \(L_B(\beta) = \log \sigma(\bar{s}(x, y_0; \beta)) + \sum_{j=1}^{K} \log(1 - \sigma(\bar{s}(x, y_j; \beta)), \)

where \((x, y_{0,K}) \sim p_{X,Y}(x, y_0) \prod_{j=1}^{K} p_N(y_j)\).

Then we have
\[
(x^{(i)}, y^{(i),0:K}) = d (x, y_0, \ldots, y_K), \quad L_B^i(\beta) = d L_B(\beta), 1 \leq i \leq n,
\]

where \(=d\) represents equal in distribution.

Throughout the proof, we will repeatedly use the following facts
\[
s'(x) = \sigma(x)(1 - \sigma(x)), \tag{25}
\]

\[
p_{X,Y}(x, y)\left(1 - \sigma(\bar{s}(x, y; \beta^*)) \right) = K p_X(x) p_N(y) \sigma(\bar{s}(x, y; \beta^*)). \tag{26}
\]

Lemma B.12 For any function \(f(\cdot, \cdot) : \mathcal{X} \times \mathcal{Y} \rightarrow \mathbb{R}^m, m \in \mathbb{N}_+\),
\[
\mathbb{E} \left[ (1 - \sigma(\bar{s}(x, y_0; \beta^*))) f(x, y_0) - \sum_{j=1}^{K} \sigma(\bar{s}(x, y_j; \beta^*)) f(x, y_j) \right] = 0
\]

where \((x, y_{0:K}) \sim p_{X,Y}(x, y_0) \prod_{j=1}^{K} p_N(y_j)\).

**Proof:** By definition,
\[
\mathbb{E} \left[ \sum_{j=1}^{K} \sigma(\bar{s}(x, y_j; \beta^*)) f(x, y_j) \right] = \sum_{x,y} p_{X,Y}(x, y) (1 - \sigma(\bar{s}(x, y; \beta^*))) f(x, y)
\]

By equality (26),
\[
\mathbb{E} \left[ \sum_{j=1}^{K} \sigma(\bar{s}(x, y_j; \beta^*)) f(x, y_j) \right] = \sum_{x,y} p_{X,Y}(x, y) (1 - \sigma(\bar{s}(x, y; \beta^*))) f(x, y)
\]

\[
\mathbb{E}[ (1 - \sigma(\bar{s}(x, y; \beta^*))) f(x, y)]
\]

\[
\square
\]

**Lemma B.13** Under the assumptions in Theorem 4.7, as \(n \rightarrow \infty\)
\[
\sqrt{n} (\hat{\beta}_B - \beta^*) \rightarrow \mathcal{N}(0, V_B)
\]

where \(V_B\) is defined as
\[
\mathbb{E} \left[ \nabla^2_{\beta} L_B(\beta^*) \right]^{-1} \text{Var} \left[ \nabla_{\beta} L_B(\beta^*) \right] \mathbb{E} \left[ \nabla^2_{\beta} L_B(\beta^*) \right]^{-1}
\]

**Proof:** The proof follows the same arguments as the proof of Lemma B.5 and we leave out the details.

**Define** the following quantities,
\[
\bar{\mu}_{x,K} := \mathbb{E}_{Y|X=x} \left[ (1 - \sigma(\bar{s}(x, y; \beta^*))) \times \nabla_{\beta} \bar{s}(x, y; \beta^*) \right],
\]
\[
\bar{W}_K := \mathbb{E}_{p_{X,Y}} \left[ (1 - \sigma(\bar{s}(x, y; \beta^*))) \times \nabla_{\beta} \bar{s}(x, y; \beta^*) \nabla_{\beta} \bar{s}(x, y; \beta^*)^\top \right].
\]
Lemma B.14

\[ E[-\nabla^2_{\beta}L_B(\beta^*)] = \tilde{W}_K \]

Var \[ \nabla_{\beta}L_B(\beta^*) \] = \( \tilde{W}_K - \frac{K+1}{K} \mathbb{E}_X[\tilde{\mu}_{x,K}(\tilde{\mu}_{x,K})^T] \)

Proof: By straightforward calculation,

\[ \nabla_{\beta}L_B(\beta^*) = (1 - \sigma(\tilde{s}(x, y_0; \beta^*)))\nabla_{\beta}\tilde{s}(x, y_0; \beta^*) \]

\[ - \sum_{j=1}^{K} \sigma(\tilde{s}(x, y_j; \beta^*))\nabla_{\beta}\tilde{s}(x, y_j; \beta^*) \]

\[ \nabla^2_{\beta}L_B(\beta^*) = -\sigma(\tilde{s}(x, y_0; \beta^*)) (1 - \sigma(\tilde{s}(x, y_0; \beta^*))) \]

\[ \times \nabla_{\beta}\tilde{s}(x, y_0; \beta^*)\nabla_{\beta}\tilde{s}(x, y_0; \beta^*)^T \]

\[ + (1 - \sigma(\tilde{s}(x, y_0; \beta^*))) \nabla^2_{\beta}\tilde{s}(x, y_0; \beta^*) \]

\[ - \sum_{j=1}^{K} \sigma(\tilde{s}(x, y_j; \beta^*)) \nabla^2_{\beta}\tilde{s}(x, y_j; \beta^*) \]

\[ - \sum_{j=1}^{K} \sigma(\tilde{s}(x, y_j; \beta^*)) (1 - \sigma(\tilde{s}(x, y_j; \beta^*))) \]

\[ \times \nabla_{\beta}\tilde{s}(x, y_j; \beta^*)\nabla_{\beta}\tilde{s}(x, y_j; \beta^*)^T \]

\[ := -I_1 + I_2 - I_3 - I_4 \]

By Lemma B.12,

\[ \mathbb{E}[I_2 - I_3] = 0. \]

Since \((x, y_0) \sim p_{X,Y}(x, y_0)\) and \((x, y_j) \sim p_{X}(x)p_{N}(y_j)\) for all \(j \geq 1, \)

\[ \mathbb{E}[I_1] = \sum_{x,y} p_{X,Y}(x, y) (1 - \sigma(\tilde{s}(x, y; \beta^*))) \]

\[ \times \sigma(\tilde{s}(x, y; \beta^*)) \nabla_{\beta}\tilde{s}(x, y; \beta^*)\nabla_{\beta}\tilde{s}(x, y; \beta^*)^T \]

\[ \mathbb{E}[I_4] = K \sum_{x,y} p_{X,Y}(x, y) (1 - \sigma(\tilde{s}(x, y; \beta^*))) \]

\[ \times \sigma(\tilde{s}(x, y; \beta^*)) \nabla_{\beta}\tilde{s}(x, y; \beta^*)\nabla_{\beta}\tilde{s}(x, y; \beta^*)^T \]

By equality (26),

\[ \mathbb{E}[I_4] = \sum_{x,y} p_{X,Y}(x, y) (1 - \sigma(\tilde{s}(x, y; \beta^*)))^2 \]

\[ \times \nabla_{\beta}\tilde{s}(x, y; \beta^*)\nabla_{\beta}\tilde{s}(x, y; \beta^*)^T \]

Therefore,

\[ \mathbb{E}[-\nabla^2_{\beta}L_B(\beta^*)] = \mathbb{E}[I_1 + I_4] \]

\[ = \sum_{x,y} p_{X,Y}(x, y) (1 - \sigma(\tilde{s}(x, y; \beta^*))) \]

\[ \times \nabla_{\beta}\tilde{s}(x, y; \beta^*)\nabla_{\beta}\tilde{s}(x, y; \beta^*)^T \]

\[ = \tilde{W}_K \]

By Lemma B.12, \( \mathbb{E}[L_B(\beta^*)] = 0 \) and hence

\[ \text{Var} \[ L_B(\beta^*) \] = \mathbb{E}[\nabla_{\beta}L_B(\beta^*)\nabla_{\beta}L_B(\beta^*)^T]. \]

Observe that,

\[ \nabla_{\beta}L_B(\beta^*)\nabla_{\beta}L_B(\beta^*)^T = I_1 - I_2 - I_3^2 + I_3 \]

where

\[ I_1 = (1 - \sigma(\tilde{s}(x, y_0; \beta^*)))^2 \]

\[ \times \nabla_{\beta}\tilde{s}(x, y_0; \beta^*)\nabla_{\beta}\tilde{s}(x, y_0; \beta^*)^T, \]

\[ I_2 = \sum_{j=1}^{K} \sigma(\tilde{s}(x, y_j; \beta^*)) (1 - \sigma(\tilde{s}(x, y_0; \beta^*))) \]

\[ \times \nabla_{\beta}\tilde{s}(x, y_j; \beta^*)\nabla_{\beta}\tilde{s}(x, y_j; \beta^*)^T, \]

\[ I_3 = \sum_{j=1}^{K} \sigma(\tilde{s}(x, y_j; \beta^*)) \sigma(\tilde{s}(x, y_l; \beta^*)) \]

\[ \times \nabla_{\beta}\tilde{s}(x, y_j; \beta^*)\nabla_{\beta}\tilde{s}(x, y_l; \beta^*)^T. \]

By definition,

\[ \mathbb{E}[I_1] = \sum_{x,y} p_{X,Y}(x, y) (1 - \sigma(\tilde{s}(x, y; \beta^*)))^2 \]

\[ \times \nabla_{\beta}\tilde{s}(x, y; \beta^*)\nabla_{\beta}\tilde{s}(x, y; \beta^*)^T. \]

Notice that \((x, y_0, y_j) \sim p_{X,Y}(x, y_0)p_{N}(y_j)\),

\[ \mathbb{E}[I_2] = K \sum_{x,y,y} p_{X,Y}(x, y) p_{N}(y) \]

\[ \times \sigma(\tilde{s}(x, y; \beta^*)) (1 - \sigma(\tilde{s}(x, y; \beta^*))) \]

\[ \times \nabla_{\beta}\tilde{s}(x, y; \beta^*)\nabla_{\beta}\tilde{s}(x, y; \beta^*)^T. \]

By equation (26),

\[ \mathbb{E}[I_2] = \sum_{x,y,y} p_{X}(x)p_{Y|X}(y|x)p_{Y|X}(\tilde{y}|x) \]

\[ (1 - \sigma(\tilde{s}(x, \tilde{y}; \beta^*)))(1 - \sigma(\tilde{s}(x, y; \beta^*))) \]

\[ \times \nabla_{\beta}\tilde{s}(x, \tilde{y}; \beta^*)\nabla_{\beta}\tilde{s}(x, y; \beta^*)^T \]

\[ = \sum_{x} p_{X}(x) \tilde{\mu}_{x,K}(\tilde{\mu}_{x,K})^T \]

\[ = \mathbb{E}[\tilde{\mu}_{x,K}(\tilde{\mu}_{x,K})^T]. \]

We decompose \( I_3 \) into two parts:

\[ I_3 = \sum_{j=1}^{K} \sigma^2(\tilde{s}(x, y_j; \beta^*)) \]

\[ \times \nabla_{\beta}\tilde{s}(x, y_j; \beta^*)\nabla_{\beta}\tilde{s}(x, y_j; \beta^*)^T \]

\[ + \sum_{1 \leq j \neq l \leq K} \sigma(\tilde{s}(x, y_j; \beta^*)) \sigma(\tilde{s}(x, y_l; \beta^*)) \]

\[ \times \nabla_{\beta}\tilde{s}(x, y_j; \beta^*)\nabla_{\beta}\tilde{s}(x, y_l; \beta^*)^T \]

\[ = I_3^1 + I_3^2 \]
Notice that \( (x, y_j) \sim p_X(x)p_N(y_j) \), then again by equation (26),
\[
\mathbb{E}[I_{13}^2] = K \sum_{x,y} p_X(x)p_N(y) \sigma^2(\tilde{s}(x, y; \beta^*))
\times \nabla \tilde{s}(x, y; \beta^*) \nabla \tilde{s}(x, y; \beta^*)^\top
= \sum_{x,y} p_{X,Y}(x, y)((1 - \sigma(\tilde{s}(x, y; \beta^*)))
\times \sigma(\tilde{s}(x, y; \beta^*)) \nabla \tilde{s}(x, y; \beta^*) \nabla \tilde{s}(x, y; \beta^*)^\top,
\]
\[
\mathbb{E}[I_1 + I_3^2] = \sum_{x,y} p_{X,Y}(x, y)((1 - \sigma(\tilde{s}(x, y; \beta^*)))
\times \nabla \tilde{s}(x, y; \beta^*) \nabla \tilde{s}(x, y; \beta^*)^\top = \tilde{W}_K.
\]

Also notice that \((x, y_j, y_i) \sim p_X(x)p_N(y_j)p_N(y_i)\) for \(1 \leq l \neq j \leq K\),
\[
\mathbb{E}[I_3^2] = (K^2 - K) \sum_{x,y} p_X(x)p_N(y) p_N(\bar{y})
\times \sigma(\tilde{s}(x, y; \beta^*)) \sigma(\tilde{s}(x, \bar{y}; \beta^*))
\times \nabla \tilde{s}(x, y; \beta^*) \nabla \tilde{s}(x, \bar{y}; \beta^*)^\top
= (1 - 1/K) \sum_x p_X(x) \tilde{\mu} x, K(\tilde{\mu} x, K)^\top
= (1 - 1/K) \mathbb{E}_X [\tilde{\mu} x, K(\tilde{\mu} x, K)^\top].
\]

where we apply equation (26) to obtain the second equality. Combining these quantities,
\[
\text{Var}[\nabla B(\beta^*)] = \tilde{W}_K - (1 + 1/K) \mathbb{E}_X [\tilde{\mu} x, K(\tilde{\mu} x, K)^\top]
\]

Define the following quantities,
\[
\mu = \mathbb{E}[\nabla \tilde{s}(x, y; \theta^*)], \quad \tilde{\mu} = \begin{bmatrix} \mu \\ -1 \end{bmatrix},
\]
\[
\tilde{\mu} x = \begin{bmatrix} \mathbb{E}_{Y|X=x}[\nabla \tilde{s}(x, y; \theta^*)] \\ -1 \end{bmatrix}, \quad \tilde{W} = \begin{bmatrix} W & -\mu \\ -\mu^\top & 1 \end{bmatrix}
\]
\[
W = \mathbb{E} \left[ \nabla \tilde{s}(x, y; \theta^*) \nabla \tilde{s}(x, y; \theta^*)^\top \right], \quad \tilde{V}_K = \tilde{W}_K^{-1} \left( \tilde{W}_K - K + \frac{1}{K} \mathbb{E}_X [\tilde{\mu} x, K(\tilde{\mu} x, K)^\top] \right)^{-1} \tilde{W}_K^{-1}
\]
\[
\tilde{V} = \tilde{W}^{-1} \left( \tilde{W} - \tilde{\mu} \tilde{\mu}^\top \right) \tilde{W}^{-1}
\]

**Lemma B.15** Under Assumption 2.2, the Fisher information matrix can be simplified to
\[
\mathcal{I}_{\theta^*} = \text{Var}_{X,Y}[\nabla \tilde{s}(x, y; \theta^*)],
\]

**Proof:** Notice that
\[
1 = \sum_{y \in \mathcal{Y}} p_{Y|X}(y|x) = \sum_{y \in \mathcal{Y}} \exp(s(x, y; \theta^*) + \gamma^*)
\]
\[
1 = \sum_{x \in X, y \in \mathcal{Y}} p_{X,Y}(x, y) = \sum_{x \in X, y \in \mathcal{Y}} p_{X}(x) \exp(s(x, y; \theta^*) - \gamma^*).
\]

Hence,
\[
\exp(\gamma^*) = \sum_{y \in \mathcal{Y}} \exp(s(x, y; \theta^*))
\]
\[
= \sum_{x \in X, y \in \mathcal{Y}} p_{X}(x) \exp(s(x, y; \theta^*)).
\]

Take derivative w.r.t. \(\theta\) on both sides,
\[
\sum_{y \in \mathcal{Y}} \exp(s(x, y; \theta^*)) \nabla \tilde{s}(x, y; \theta^*)
\]
\[
= \sum_{x \in X, y \in \mathcal{Y}} p_{X}(x) \exp(s(x, y; \theta^*)) \nabla \tilde{s}(x, y; \theta^*)
\]

which implies
\[
\mathbb{E}_{Y|X=x}[\nabla \tilde{s}(x, y; \theta^*)]
\]
\[
= \sum_{x \in X, y \in \mathcal{Y}} p_{X}(x) \exp(s(x, y; \theta^*) - \gamma^*)
\]
\[
\times \nabla \tilde{s}(x, y; \theta^*)
\]
\[
= \mathbb{E}_{X,Y}[\nabla \tilde{s}(x, y; \theta^*)].
\]

So \(\mathbb{E}_{Y|X=x}[\nabla \tilde{s}(x, y; \theta^*)]\) is independent of \(x\) and
\[
\text{Var}_X[\mathbb{E}_{Y|X=x}[\nabla \tilde{s}(x, y; \theta^*)]] = 0.
\]

Finally, by the law of total variance,
\[
\text{Var}_{X,Y}[\nabla \tilde{s}(x, y; \theta^*)]
\]
\[
= \mathbb{E}_X \left[ \text{Var}_{Y|X=x}[\nabla \tilde{s}(x, y; \theta^*)] \right]
\]
\[
+ \text{Var}_X \left[ \mathbb{E}_{Y|X=x}[\nabla \tilde{s}(x, y; \theta^*)] \right]
\]
\[
= \mathbb{E}_X \left[ \text{Var}_{Y|X=x}[\nabla \tilde{s}(x, y; \theta^*)] \right] + 0
\]
\[
= \mathcal{I}_{\theta^*}.
\]

**Lemma B.16** Under the assumptions in Theorem 4.7, \(W\) and \(\tilde{W}\) are non-singular and
\[
\tilde{V} = \begin{bmatrix} \frac{\mathcal{I}_{\theta^*}^{-1}}{\mu^\top W^{-1} \mu} & \frac{W^{-1}}{1 - \mu^\top W^{-1} \mu} \\ \frac{W^{-1}}{1 - \mu^\top W^{-1} \mu} & \frac{1}{\mu^\top W^{-1} \mu} \end{bmatrix}
\]

Proof: Notice that,

\[ W - \mu \mu^T = E[\nabla_\theta \tilde{s}(x, y; \theta^*) \nabla_\theta \tilde{s}(x, y; \theta^*)^T] \]
\[ - E[\nabla_\theta \tilde{s}(x, y; \theta^*)] E[\nabla_\theta \tilde{s}(x, y; \theta^*)^T] \]
\[ = \text{Var}[\nabla_\theta \tilde{s}(x, y; \theta^*)] \]

By Lemma B.15,
\[ W = \mathcal{I}_{\theta^*} + \mu \mu^T. \]

Since \( \mathcal{I}_{\theta^*} \) is non-singular, \( W \) is strictly positive definite and by Sherman-Morrison formula,
\[ W^{-1} = \mathcal{I}_{\theta^*}^{-1} - \frac{\mathcal{I}_{\theta^*}^{-1} \mu \mu^T \mathcal{I}_{\theta^*}^{-1}}{1 + \mu^T \mathcal{I}_{\theta^*}^{-1} \mu} \]

and
\[ \mu^T W^{-1} \mu = \frac{\mu^T \mathcal{I}_{\theta^*}^{-1} \mu}{1 + \mu^T \mathcal{I}_{\theta^*}^{-1} \mu} > 0. \]

Therefore, by block matrix inversion formula, \( \tilde{W} \) is non-singular and
\[ \tilde{W}^{-1} = \begin{bmatrix} W & -\mu \\ -\mu^T & 1 \end{bmatrix}^{-1} \]
\[ = \begin{bmatrix} \mathcal{I}_{\theta^*}^{-1} & \frac{W^{-1} \mu}{1 - \mu^T W^{-1} \mu} \\ \frac{-W^{-1} \mu}{1 - \mu^T W^{-1} \mu} & \frac{1}{1 - \mu^T W^{-1} \mu} \end{bmatrix}. \]

Notice that,
\[ \tilde{W} - \tilde{\mu} \tilde{\mu}^T = \begin{bmatrix} \mathcal{I}_{\theta^*} & 0 \\ 0 & 0 \end{bmatrix}. \]

We then have,
\[ \tilde{W}^{-1} \left( \tilde{W} - \tilde{\mu} \tilde{\mu}^T \right) \tilde{W}^{-1} = \begin{bmatrix} \mathcal{I}_{\theta^*}^{-1} & \frac{W^{-1} \mu}{1 - \mu^T W^{-1} \mu} \\ \frac{-W^{-1} \mu}{1 - \mu^T W^{-1} \mu} & \frac{1}{1 - \mu^T W^{-1} \mu} \end{bmatrix}. \]

\[ \Box \]

Lemma B.17 Under the assumptions in Theorem 4.7, there exists an integer \( K_0 \) and positive constant \( C > 0 \) such that for all \( K \geq K_0, \tilde{W}_K \) is non-singular and

\[ \sup_x \| \tilde{\mu}_{x,K} - \tilde{\mu}_x \|, \| \tilde{W}_K^{-1} - \tilde{W}^{-1} \| \leq C/K \]
\[ \left\| E_X [\tilde{\mu}_{x,K} (\tilde{\mu}_{x,K})^T] - E_X [\tilde{\mu}_x \tilde{\mu}_x^T] \right\| \leq C/K \]
\[ \left\| E_X [\tilde{\mu}_{x,K} (\tilde{\mu}_{x,K})^T] \right\|, \| \tilde{W}_K^{-1} \| \leq C \]

Proof: By definition and Lemma B.8,
\[ \sigma(\tilde{s}(x, y; \beta^*)) = \frac{\exp(\tilde{s}(x, y; \theta^*) + \gamma^*)}{K + \exp(\tilde{s}(x, y; \theta^*) + \gamma^*)} \]
\[ \leq \frac{C_1}{K}. \]

Notice that,
\[ \mu_{x,K} = E_{Y | x = x} \left[ \nabla_\theta \tilde{s}(x, y; \theta^*) \right] \]
\[ - E_{Y | x = x} \left[ \sigma(\tilde{s}(x, y; \beta^*)) \nabla_\theta \tilde{s}(x, y; \theta^*) \right] \]
\[ = \tilde{\mu}_x - \Delta_\tilde{\mu}_x,K, \]

where \( \Delta_\tilde{\mu}_x,K = \]
\[ E_{Y | x = x} \left[ \sigma(\tilde{s}(x, y; \beta^*)) \left[ \nabla_\theta \tilde{s}(x, y; \theta^*) \right] \right] \]

Again by Lemma B.8,
\[ \| \Delta_\tilde{\mu}_x,K \| \leq \frac{C_1 \sup_{x,y} \| \nabla_\theta \tilde{s}(x, y; \theta^*) \|}{1} \]
\[ \leq \frac{C_1 (C + 1)}{K}. \]

Observe that \( E_X [\tilde{\mu}_{x,K} (\tilde{\mu}_{x,K})^T] = E_X [\tilde{\mu}_x \tilde{\mu}_x^T] + \Delta_\mu \), where
\[ \Delta_\mu = E_X [\tilde{\mu}_x \nabla_\theta \tilde{s}(x, y; \theta^*)] + E_X [\nabla_\theta \tilde{s}(x, y; \theta^*) \tilde{\mu}_x] \]
\[ + E_X [\nabla_\theta \tilde{s}(x, y; \beta^*) \nabla_\theta \tilde{s}(x, y; \theta^*) \tilde{\mu}_x] \]
\[ + E_X [\nabla_\theta \tilde{s}(x, y; \beta^*) \nabla_\theta \tilde{s}(x, y; \theta^*) \tilde{\mu}_x]. \]

Similarly, by Lemma B.8, \( \sup_x \| \tilde{\mu}_x \| \leq C + 1 \). Therefore, there exist constants \( C_3, C_4 \) such that
\[ \| \Delta_\mu \| \leq 2 \sup_x \| \tilde{\mu}_x \| \| \nabla_\theta \tilde{s}(x, y; \theta^*) \| + \sup_x \| \Delta_\tilde{\mu}_x,K \|^2 \]
\[ \leq \frac{C_3}{K}. \]
\[ \| E_X [\tilde{\mu}_{x,K} (\tilde{\mu}_{x,K})^T] \| \leq \sup_x \| \tilde{\mu}_x \|^2 + \| \Delta_\mu \| \leq C_4. \]

On the other hand, \( \tilde{W}_K = \tilde{W} + \Delta \tilde{W}_K \), where
\[ \Delta \tilde{W}_K = E \left[ \sigma(\tilde{s}(x, y; \beta^*)) \right. \]
\[ \times \left. \left[ \nabla_\theta \tilde{s}(x, y; \theta^*) \right] \right] \left[ \nabla_\theta \tilde{s}(x, y; \theta^*) \right]^T. \]
By the same reasoning,
\[
\begin{align*}
\left\| \Delta \tilde{W}_K \right\| & \leq \frac{C_1 \sup_{K \in x, y} \left\| \nabla_{\theta \delta}(x, y; \theta^*) \right\|}{\left\| \nabla_{\theta \delta}(x, y; \theta^*) \right\|} \\
& \leq \frac{C_1 (C + 1)^2}{K}.
\end{align*}
\]

Let \( \sigma_{\min}(\cdot) \) denote the smallest singular value a matrix. By Lemma B.16, \( \tilde{W} \) is non-singular. So there exists \( K_0 \) such that \( \sigma_{\min}(\tilde{W}) \geq 2 \left\| \Delta \tilde{W}_K \right\| \). Therefore, for any \( K \geq K_0 \), by Weyl’s inequality,
\[
\sigma_{\min}(\tilde{W}_K) \geq \sigma_{\min}(\tilde{W}) - \left\| \Delta \tilde{W}_K \right\| \\
\geq \sigma_{\min}(\tilde{W}) / 2.
\]

Then
\[
\left\| \tilde{W}_K^{-1} \right\| = \frac{1}{\sigma_{\min}(\tilde{W}_K)} \leq \frac{2}{\sigma_{\min}(\tilde{W})}.
\]

This implies,
\[
\begin{align*}
\left\| \tilde{W}_K^{-1} - \tilde{W}^{-1} \right\| & = \left\| \tilde{W}_K^{-1}(\tilde{W} - \tilde{W}_K)\tilde{W}_K^{-1} \right\| \\
& \leq \left\| \tilde{W}_K^{-1} \right\| \left\| \tilde{W} - \tilde{W}_K \right\| \left\| \tilde{W}_K^{-1} \right\| \\
& \leq \frac{2}{\sigma_{\min}(\tilde{W})} \times \left\| \Delta \tilde{W}_K \right\| \times \frac{1}{\sigma_{\min}(\tilde{W})} \\
& \leq \frac{2C_1 (C + 1)^2}{\sigma_{\min}(\tilde{W})^2 K} \\
& \leq \frac{C_5}{K}
\end{align*}
\]

for some constant \( C_5 \). \( \Box \)

**Proof of Theorem 4.7.** By Lemma B.13 and Lemma B.14,
\[
\begin{align*}
\sqrt{n}(\hat{\beta} - \beta^*) & \to N(0, \tilde{V}_K), \\
\tilde{V}_K - \tilde{V} & = \left( \tilde{W}_K^{-1} - \tilde{W}^{-1} \right) \\
& - \frac{1}{K} \tilde{W}_K^{-1} \mathbb{E}_X \left[ \tilde{\mu}_{x,K}(\tilde{\mu}_{x,K})^\top \right] \tilde{W}_K^{-1} \\
& + \left( \tilde{W}_K^{-1} - \tilde{W}^{-1} \right) \mathbb{E}_X \left[ \tilde{\mu}_{x,K}(\tilde{\mu}_{x,K})^\top \right] \tilde{W}_K^{-1} \\
& + \tilde{W}^{-1} \left( \mathbb{E}_X \left[ \tilde{\mu}_{x,K}(\tilde{\mu}_{x,K})^\top \right] - \mathbb{E}_X \left[ \tilde{\mu}_{x,K} \tilde{\mu}_{x,K}^\top \right] \right) \tilde{W}_K^{-1} \\
& + \tilde{W}^{-1} \mathbb{E}_X \left[ \tilde{\mu}_{x,K} \tilde{\mu}_{x,K}^\top \right] \left( \tilde{W}_K^{-1} - \tilde{W}^{-1} \right)
\end{align*}
\]

Applying Lemma B.17, there exist constants \( C \) and integer \( K' \) such that for some constant \( C \) and all \( K \geq K' \).
\[
\left\| \tilde{V}_K - \tilde{V} \right\| \leq \frac{C}{K}.
\]

Recall \( \theta \in \mathbb{R}^d \). Define \( V_K \) as the upper \( d \times d \) block of \( \tilde{V}_K \). Since \( \mathcal{I}_0^{-1} \) is the upper \( d \times d \) block of \( \tilde{V} \), for all \( K \geq K' \),
\[
\left\| V_K - \mathcal{I}_0^{-1} \right\| \leq \left\| \tilde{V}_K - \tilde{V} \right\| \leq \frac{C}{K}.
\]

Choose \( K_0 \) large enough such that \( K_0 \geq K' \) and
\[
\sigma_{\min}(\mathcal{I}_0^{-1}) \geq 2C/K_0.
\]

Then by Weyl’s inequality, for all \( K \geq K_0 \)
\[
\sigma_{\min}(V_K) \geq \sigma_{\min}(\mathcal{I}_0^{-1}) - \left\| V_K - \mathcal{I}_0^{-1} \right\| \\
\geq \sigma_{\min}(\mathcal{I}_0^{-1}) - \frac{C}{K_0} \geq \frac{\sigma_{\min}(\mathcal{I}_0^{-1})}{2}.
\]

Therefore, \( V_K \) is non-singular and we can define \( \mathcal{I}_{B,K} = V_K^{-1} \). Then for all \( K \geq K_0 \)
\[
\sqrt{n}(\hat{\theta}_B - \theta^*) \to N(0, \mathcal{I}_{B,K}^{-1}).
\]

\[
\left\| \mathcal{I}_{B,K}^{-1} - \mathcal{I}_0^{-1} \right\| = \left\| V_K - \mathcal{I}_0^{-1} \right\| \leq \frac{C}{K}.
\]

Finally, notice that \( \hat{\theta}_B, \hat{\theta}^{\text{MLE}} \) are asymptotically unbiased,
\[
\begin{align*}
| \text{MSE}_\infty(\hat{\theta}_B) - \text{MSE}_\infty(\hat{\theta}^{\text{MLE}}) | & = | \text{Tr}(\mathcal{I}_{B,K}^{-1} - \mathcal{I}_0^{-1}) / d | \\
& \leq d \left\| \mathcal{I}_{R,K}^{-1} - \mathcal{I}_0^{-1} \right\| / d \leq \frac{C}{K}.
\end{align*}
\]
