Abstract

In this paper, we give an overview on optimality conditions and exact penalization for the mathematical program with switching constraints (MPSC). MPSC is a new class of optimization problems with important applications. It is well known that if MPSC is treated as a standard nonlinear program, some of the usual constraint qualifications may fail. To deal with this issue, one could reformulate it as a mathematical program with disjunctive constraints (MPDC). In this paper, we first survey recent results on constraint qualifications and optimality conditions for MPDC, then apply them to MPSC. Moreover, we provide two types of sufficient conditions for the local error bound and exact penalty results for MPSC. One comes from the directional quasi-normality for MPDC, and the other is obtained via the local decomposition approach.

1 Introduction

The mathematical program with switching constraints (MPSC) defines a class of optimization problems in which some of the equality constraint functions are products of two functions. The terminology “switching constraint” comes from the fact that if the product of two constraint functions is equal to zero, then at least one of them must be equal to zero. MPSC can be used to model the discretized version of the optimal control problem with switching structure (see, e.g., [10, 24, 31] and the references therein), or to reformulate the so-called mathematical programs with either-or-constraints (see [31, Section 7]). MPSC has many interesting applications, e.g., optimal control with switching structures has been used to model certain real-world applications [18, 20, 37] and the mathematical program with either-or-constraints was used to study some special instances of portfolio optimization [24].

It is well known that if the mathematical program with equilibrium constraints (MPEC) [27, 33], or the mathematical program with vanishing constraints (MPVC) [1, 22], is treated as nonlinear programs, then there are issues involving the usual constraint qualifications such as the Mangasarian–Fromovitz constraint qualification (MFCQ) and/or the linear independence constraint qualification (LICQ) for MPEC and MPVC. It is not surprising that this issue also exists for MPSC. Indeed, Mehlitz [31, Lemma 4.1] showed that if an MPSC is treated as a nonlinear program, then MFCQ fails at any feasible point $z^*$ for which there is a pair of switching functions with value equal to zero. Consequently, he introduced the concepts of weak, Mordukhovich (M-), and strong (S-) stationarity for MPSC and presented some associated constraint qualifications. Kanzow et al. [24] adopted several relaxation methods from the numerical treatment of MPEC to MPSC. Li and Guo extended some weak and verifiable constraint qualifications for nonlinear programs to MPSC in [26]. In the work of [26, 31], the error bound property was not studied and that is one of the main focuses of this paper.

The mathematical program with disjunctive constraints (also called the disjunctive program) is a type of set-constrained optimization problem where the set is the union of finitely many polyhedral convex sets. Programs such as MPEC, MPVC and MPSC can be reformulated as disjunctive programs. The classical concepts of optimality for disjunctive programs such as S-stationary condition based on the regular normal cone and M-stationary condition based on the limiting/Mordukhovich normal cone for disjunctive programs were introduced by Flegel et al. [11]. Although M-stationary condition holds for a local minimizer under very weak constraint qualifications such as the generalized Guignard constraint qualification (GGCQ), it may be weak for some problems and it does not exclude feasible descent directions. Based on concepts of metric subregularity and some new developments in variational analysis, for disjunctive programs, Gfrerer [14] introduced various new concepts of constraint qualifications and stationarity concepts including the strong M-stationarity and the extended M-stationarity which are stronger than M-stationarity. Moreover, a directional version of LICQ and directional first- and second-order optimality conditions is given in [14].

Another direction of sharpening optimality conditions and weakening constraint qualifications is to consider directional optimality conditions and constraint qualifications. Bai et al. [5] introduced the directional quasi/pseudo-normality as sufficient conditions.
for the metric subregularity which are weaker than both the classical quasi/pseudo-normality and the first-order sufficient condition for metric subregularity. Benko et al. [6] generalized the notions of directional pseudo- and quasi-normality to obtain more sufficient conditions for metric subregularity. In particular, they have shown that for the disjunctive program, the (directional) pseudo-normality can always take the simplified form while for a special class of the disjunctive program called the ortho-disjunctive program (which includes MPSC), the (directional) quasi-normality can also take the simplified form. Mehlitz [30] introduced an alternative concept of LICQ and obtained first- and second-order optimality conditions for disjunctive programs. Recall that M-stationary condition does not preclude the existence of feasible descent directions. To deal with this issue, recently Benko and Gfrerer [7] introduced the so-called Q-stationarity and $Q_M$-stationarity where $Q_M$-stationarity is stronger than M-stationarity. A further extension of Q-stationarity and $Q_M$-stationarity is presented in Benko and Gfrerer [8]. To deal with the difficulty of calculating the limiting normal cone to the feasible region, Gfrerer [15] introduced a new concept of stationary condition for a set-constrained optimization problem called the linearized M-stationary condition. Recently, sequential optimality conditions and constraint qualifications and their applications in numerical algorithms became a popular topic. A suitable theory has been developed in the context of MPEC in [4,35]. Mehlitz [29] has generalized the underlying theories to a very general optimization problem which includes MPDC as a special case.

In this paper, we will survey the aforementioned results about new stationarity concepts and sufficient conditions for metric subregularity for disjunctive programs. We then apply these results to obtain various optimality conditions and local error bound results for MPSC. Moreover, we propose to use the local decomposition approach to study sufficient conditions for the error bound property by the corresponding constraint qualifications for each branch as a standard nonlinear program (NLP).

The remainder of this paper is organized as follows. In Sect. 2, we review some constraint qualifications from nonlinear programs, and existing constraint qualifications and optimality conditions for MPSC. In Sect. 3, we summarize the results that we need for disjunctive programs. In Sect. 4, we apply the results from Sect. 3 to MPSC. In Sect. 5, we derive the local error bound and exact penalty results for MPSC. In Sect. 6, we conclude our discussion and provide relationships among various constraint qualifications, error bound properties and stationary conditions.

Throughout the paper, for a differentiable mapping $c : \mathbb{R}^n \to \mathbb{R}^m$ and a vector $z \in \mathbb{R}^n$, we denote by $\nabla c(z)$ the Jacobian of $c$ at $z$. For a differentiable function $f : \mathbb{R}^n \to \mathbb{R}$, we denote by $\nabla f(z)$ its gradient vector and $\nabla^2 f(z)$ its Hessian matrix at $z$ provided that it is twice differentiable. For a set $C$, we denote by $C^\circ := \{x | x^T y \leq 0, \forall y \in C\}$ its polar cone, and by $\text{dist}_C(x)$ the distance between $x$ and $C$. Unless otherwise specified, $\| \cdot \|$ denotes an arbitrary norm in $\mathbb{R}^n$.

2 Review of Constraint Qualifications and Optimality Conditions

In this section, we first recall some constraint qualifications for NLP. Then, we review some existing constraint qualifications and optimality conditions for MPSC. The reader
is referred to [26,31] for those constraint qualifications for MPSC that are not reviewed here.

\section{Constraint Qualifications for NLP}

Consider the standard nonlinear program

$$
\min f(z) \quad \text{s.t. } g(z) \leq 0, \ h(z) = 0,
$$

where $f : \mathbb{R}^n \to \mathbb{R}, g : \mathbb{R}^n \to \mathbb{R}^p, h : \mathbb{R}^n \to \mathbb{R}^q$ are continuously differentiable. Denote by $\bar{I}_g := I_g(\bar{z}) = \{i \in \{1, \cdots, p\} | g_i(\bar{z}) = 0\}$ the index set of active inequality constraints at $\bar{z}$. We recall some constraint qualifications for problem (1) that we will refer to in this paper.

\begin{definition}
Let $\bar{z} \in \mathbb{R}^n$ be a feasible point of problem (1). We say that $\bar{z}$ satisfies

1. linear independence constraint qualification (LICQ), if the family of gradients $\{\nabla g_i(\bar{z})\}_{i \in \bar{I}_g} \cup \{\nabla h_i(\bar{z})\}_{i = 1}^q$ is linearly independent;
2. Mangasarian-Fromovitz constraint qualification (MFCQ) [28], or equivalently positive-linearly independent constraint qualification (PLICQ) if the family of gradients $\{\nabla g_i(\bar{z})\}_{i \in \bar{I}_g} \cup \{\nabla h_i(\bar{z})\}_{i = 1}^q$ is positive-linearly independent, i.e., the family of gradients $\{\nabla g_i(\bar{z})\}_{i \in \bar{I}_g} \cup \{\nabla h_i(\bar{z})\}_{i = 1}^q$ is linearly independent with non-negative scalars associated with the gradients of the active inequality constraints;
3. constant rank constraint qualification (CRCQ) [23], if there exists a neighborhood $\mathcal{N}(\bar{z})$ of $\bar{z}$ such that for every $I \subseteq \bar{I}_g$ and every $J \subseteq \{1, \cdots, q\}$, the family of gradients $\{\nabla g_i(z)\}_{i \in I} \cup \{\nabla h_i(z)\}_{i \in J}$ has the same rank for every $z \in \mathcal{N}(\bar{z})$;
4. relaxed constant rank constraint qualification (RCRCQ) [32], if there exists a neighborhood $\mathcal{N}(\bar{z})$ of $\bar{z}$ such that for every $I \subseteq \bar{I}_g$, the family of gradients $\{\nabla g_i(z)\}_{i \in I} \cup \{\nabla h_i(z)\}_{i = 1}^q$ has the same rank for every $z \in \mathcal{N}(\bar{z})$;
5. constant positive linear dependence constraint qualification (CPLD) [34], if there exists a neighborhood $\mathcal{N}(\bar{z})$ of $\bar{z}$ such that for every $I \subseteq \bar{I}_g$ and every $J \subseteq \{1, \cdots, q\}$, whenever the family of gradients $\{\nabla g_i(\bar{z})\}_{i \in I} \cup \{\nabla h_i(\bar{z})\}_{i \in J}$ is positive-linearly dependent, then $\{\nabla g_i(z)\}_{i \in I} \cup \{\nabla h_i(z)\}_{i \in J}$ is linearly dependent for every $z \in \mathcal{N}(\bar{z})$;
6. relaxed constant positive linear dependence constraint qualification (RCPLD) [2], if there exists a neighborhood $\mathcal{N}(\bar{z})$ of $\bar{z}$ such that (i) $\{\nabla h_i(z)\}_{i = 1}^q$ has the same rank for every $z \in \mathcal{N}(\bar{z})$; (ii) For every $I \subseteq \bar{I}_g$, if the family of gradients $\{\nabla g_i(\bar{z})\}_{i \in I} \cup \{\nabla h_i(\bar{z})\}_{i \in J}$ is positive-linearly dependent, where $J \subseteq \{1, \cdots, q\}$ is such that $\{\nabla h_i(\bar{z})\}_{i \in J}$ is a basis for span $\{\nabla h_i(\bar{z})\}_{i = 1}^q$, then $\{\nabla g_i(z)\}_{i \in I} \cup \{\nabla h_i(z)\}_{i \in J}$ is linearly dependent for every $z \in \mathcal{N}(\bar{z})$;
7. constant rank of subspace component (CRSC) [3], if there exists a neighborhood $\mathcal{N}(\bar{z})$ of $\bar{z}$ such that the rank of $\{\nabla g_i(z)\}_{i \in \bar{I}^-} \cup \{\nabla h_i(z)\}_{i = 1}^q$ remains constant for $z \in \mathcal{N}(\bar{z})$, where
\[ I^- = \left\{ l \in \bar{I}_g \left| -\nabla g_l(\bar{z}) \in \left\{ \sum_{i=1}^{q} \lambda_i \nabla h_i(\bar{z}) + \sum_{i \in \bar{I}_g \setminus \{l\}} \mu_i \nabla g_i(\bar{z}) | \mu_i \geq 0, i \in \bar{I}_g \right\} \right. \right\}. \]

**Remark 2.1** Let \( L(\bar{z}) := \{ d | \nabla g_l(\bar{z}) d \leq 0, \ i \in \bar{I}_g, \ \nabla h_i(\bar{z}) d = 0, \ i = 1, \ldots, q \} \) be the linearization cone of problem (1) at \( \bar{z} \). Kruger al. [25] pointed out that since the polar of the linearization cone is equal to
\[ L(\bar{z})^o = \left\{ \sum_{i=1}^{q} \lambda_i \nabla h_i(\bar{z}) + \sum_{i \in \bar{I}_g} \mu_i \nabla g_i(\bar{z}) | \mu_i \geq 0, i \in \bar{I}_g \right\}, \]
by the definition of the linearization cone, the index set \( I^- \) can be equivalently written as
\[ I^- = \{ l \in \bar{I}_g | \nabla g_l(\bar{z})^T d = 0, \ \forall d \in L(\bar{z}) \}. \]
Hence, in [25], CRSC is also called relaxed MFCQ.

**Definition 2.2** (see, e.g., [38]) Let \( \mathcal{F}_{NLP} \) be the feasible region of problem (1). We say that an error bound holds in a neighborhood \( N(\bar{z}) \) of a feasible point \( \bar{z} \in \mathcal{F}_{NLP} \) if there exists \( \alpha > 0 \) such that for every \( z \in N(\bar{z}) \)
\[ \text{dist}_{\mathcal{F}_{NLP}}(z) \leq \alpha \left( \sum_{i=1}^{p} \max\{g_i(z), 0\} + \sum_{i=1}^{q} |h_i(z)| \right). \]

It is easy to see that the local error bound condition holds at \( \bar{z} \) for NLP if and only if the feasibility mapping \( z \mapsto (g(z), h(z)) - \mathbb{R}^p_+ \times \{0\}^q \) is metrically subregular (see Definition 3.8) at \( (\bar{z}, 0) \).

Andreani al. [3, Theorem 5.5] showed that CRSC implies the existence of local error bounds under the second-order differentiability of functions \( g, h \). This assumption was removed by Guo et al. [19]. Finally, we summarize relations among constraint qualifications for NLP discussed in this subsection in Fig. 1.

### 2.2 Constraint Qualifications and Optimality Conditions for MPSC

In this paper, we consider the following MPSC:
\[
\min \ f(z) \\
\text{s.t.} \quad g(z) \leq 0, \ h(z) = 0, \ G_i(z)H_i(z) = 0, \ i = 1, \ldots, m
\] (2)

where \( f : \mathbb{R}^n \to \mathbb{R}, \quad g : \mathbb{R}^n \to \mathbb{R}^p, \quad h : \mathbb{R}^n \to \mathbb{R}^q, \quad G_1, \ldots, G_m : \mathbb{R}^n \to \mathbb{R}, \quad H_1 \ldots, H_m : \mathbb{R}^n \to \mathbb{R}. \) We assume that unless otherwise specified, all defining functions are continuously differentiable. Let \( \mathcal{F} \) denote the feasible region of (2). For a feasible point \( z^* \in \mathcal{F} \), we define some useful index sets as follows:

\[
\mathcal{I}_g^* := \mathcal{I}_g(z^*) = \{i \in \{1, \ldots, p\} \mid g_i(z^*) = 0\}, \\
\mathcal{I}_G^* := \mathcal{I}_G(z^*) = \{i \in \{i, \ldots, m\} \mid G_i(z^*) = 0, \ H_i(z^*) \neq 0\}, \\
\mathcal{I}_H^* := \mathcal{I}_H(z^*) = \{i \in \{i, \ldots, m\} \mid G_i(z^*) \neq 0, \ H_i(z^*) = 0\}, \\
\mathcal{I}_{GH}^* := \mathcal{I}_{GH}(z^*) = \{i \in \{i, \ldots, m\} \mid G_i(z^*) = H_i(z^*) = 0\}.
\]

Since by [31, Lemma 4.1], MPSC never satisfies MFCQ at a feasible point \( z^* \) with \( \mathcal{I}_{GH}^* \neq \emptyset \), Mehlitz [31] defined and studied the following alternative stationarity concepts.

**Definition 2.3** [31] We say that \( z^* \in \mathcal{F} \) is a **weakly stationary** (W-stationary) point of MPSC (2) if there exist multipliers \((\lambda^g, \lambda^h, \lambda^G, \lambda^H)\) such that

\[
\nabla f(z^*) + \sum_{i \in \mathcal{I}_g^*} \lambda^g_i \nabla g_i(z^*) + \sum_{i=1}^q \lambda^h_i \nabla h_i(z^*) + \sum_{i=1}^m (\lambda^G_i \nabla G_i(z^*) + \lambda^H_i \nabla H_i(z^*)) = 0,
\]

\[
\lambda^g_i \geq 0, \quad i \in \mathcal{I}_g^*, \quad \lambda^G_i = 0, \quad i \in \mathcal{I}_G^*, \quad \lambda^H_i = 0, \quad i \in \mathcal{I}_H^*.
\] (3) (4)

We say that \( z^* \in \mathcal{F} \) is a **Mordukhovich stationary** (M-stationary) point of MPSC (2) if there exist multipliers \((\lambda^g, \lambda^h, \lambda^G, \lambda^H)\) such that (3)–(4) hold and \( \lambda^G_i \lambda^H_i = 0, \quad i \in \mathcal{I}_{GH}^* \). Moreover, we call \((\lambda^g, \lambda^h, \lambda^G, \lambda^H)\) an M-multiplier.

We say that \( z^* \in \mathcal{F} \) is a **strongly stationary** (S-stationary) point of MPSC (2) if there exist multipliers \((\lambda^g, \lambda^h, \lambda^G, \lambda^H)\) such that (3)–(4) hold and \( \lambda^G_i = \lambda^H_i = 0, \quad i \in \mathcal{I}_{GH}^* \). Moreover, we call \((\lambda^g, \lambda^h, \lambda^G, \lambda^H)\) an S-multiplier.

Consider the associated tightened nonlinear problem at \( z^* \in \mathcal{F} \):

(TNLP) \[
\min \ f(z) \\
\text{s.t.} \quad g(z) \leq 0, \ h(z) = 0, \ G_i(z) = 0, \ i \in \mathcal{I}_G^* \cup \mathcal{I}_{GH}^*, \ H_i(z) = 0, \ i \in \mathcal{I}_H^* \cup \mathcal{I}_{GH}^*.
\]

**Definition 2.4** [31] Let \( z^* \) be a feasible point of MPSC (2). We say that \( z^* \) satisfies MPSC-LICQ/-MFCQ, if LICQ/MFCQ holds for (TNLP) at \( z^* \).

**Definition 2.5** Let \( z^* \) be a feasible point of MPSC (2). We say that \( z^* \) satisfies MPSC-CRCQ/-CPLD, if CRCQ/CPLD holds for (TNLP) at \( z^* \).
Remark 2.2  The MPSC-CRCQ/-CPLD defined in Definition 2.5 coincides with those defined in [26, Definition 4.2]. The advantage of defining these constraint qualifications as the corresponding ones for the tightened nonlinear program (TNLP) is that we can immediately conclude from the definitions of CRCQ and CPLD for nonlinear programs that MPSC-CRCQ implies MPSC-CPLD without proof as in (i) of the proof for [26, Theorem 4.2].

Definition 2.6  (MPSC-RCPLD)[26] Let $z^*$ be a feasible point of MPSC (2). We say that $z^*$ satisfies MPSC-RCPLD if there exists a neighborhood $N(z^*)$ of $z^*$ such that

(i) The vectors \( \{ \nabla h_i(z) \}_{i=1}^q \cup \{ \nabla G_i(z) \}_{i \in I^*_G} \cup \{ \nabla H_i(z) \}_{i \in I^*_H} \) have the same rank for all $z$ in $N(z^*)$;

(ii) Let $I_1 \subseteq \{1, 2, \ldots, q\}$, $I_2 \subseteq I^*_G$, $I_3 \subseteq I^*_H$ be index sets such that the set of vectors \( \{ \nabla h_i(z^*) \}_{i \in I_1} \cup \{ \nabla G_i(z^*) \}_{i \in I_2} \cup \{ \nabla H_i(z^*) \}_{i \in I_3} \) is a basis for span \( \{ \{ \nabla h_i(z^*) \}_{i=1}^q \} \cup \{ \nabla G_i(z^*) \}_{i \in I^*_G} \cup \{ \nabla H_i(z^*) \}_{i \in I^*_H} \). For each $I_4 \subseteq I^*_G$, $I_5$, $I_6 \subseteq I^*_H$, if there exist \( \lambda^G_l, \lambda^H_l, \lambda^G_r, \lambda^H_r \) not all zero, with $\lambda_i^G \geq 0$ for each $i \in I_4$ and $\lambda_i^H \neq 0$ for each $i \in I^*_H$, such that

\[
\sum_{i \in I_4} \lambda_i^G \nabla G_i(z^*) + \sum_{i \in I_1} \lambda_i^H \nabla h_i(z^*) + \sum_{i \in I_2 \cup I_5} \lambda_i^G \nabla G_i(z^*) + \sum_{i \in I_3 \cup I_6} \lambda_i^H \nabla H_i(z^*) = 0,
\]

then for any $z \in N(z^*)$, the set of vectors

\[
\{ \nabla g_i(z) \}_{i \in I_4} \cup \{ \nabla h_i(z) \}_{i \in I_1} \cup \{ \nabla G_i(z) \}_{i \in I_2 \cup I_5} \cup \{ \nabla H_i(z) \}_{i \in I_3 \cup I_6}
\]

is linearly dependent.

We now gather constraint conditions and necessary optimality conditions from [26,31] in the following theorem. One can find the definition of MPSC No Nonzero Abnormal Multiplier Constraint Qualification (MPSC-NNAMCQ) and MPSC quasi/pseudo-normality from the comments after Definitions 4.6 and 4.7, respectively.

Theorem 2.1  [26,31] Let $z^*$ be feasible for problem (2). If MPSC-LICQ is fulfilled at $z^*$, then $z^*$ is S-stationary. If MPSC-MFCQ/-CPLD/-CRCQ/-RCPLD/-NNAMCQ/- quasi/-pseudo-normality is fulfilled at $z^*$, then $z^*$ is M-stationary.

3 Optimality Conditions for Mathematical Programs with Disjunctive Constraints

In this section, we review some optimality conditions for the mathematical programs with disjunctive constraints (MPDC):

\[
\min_{z} f(z) \quad \text{s.t.} \quad P(z) \in \Lambda, \tag{5}
\]

where $f : \mathbb{R}^n \to \mathbb{R}$, $P : \mathbb{R}^n \to \mathbb{R}^m$ are continuously differentiable, and $\Lambda \subseteq \mathbb{R}^m$ is the union of finitely many convex polyhedral sets. We denote the feasible region by
\( \mathcal{F}_D := \{ z \in \mathbb{R}^n \mid P(z) \in \Lambda \} \) and the linearization cone by
\[
L_{\mathcal{F}_D}^{\text{lin}}(z^*) := \{ d \in \mathbb{R}^n \mid \nabla P(z^*)d \in T_A(P(z^*)) \}.
\]

To study the mathematical program with disjunctive constraints (5), we need to study various tangent cones and normal cones to \( \Lambda \). First, we recall definitions of tangent cones and normal cones. Suppose that \( A \subseteq \mathbb{R}^m \) is closed and \( x^* \in A \).

The tangent/Bouligand cone, the Fréchet/regular and the limiting/basic/Mordukhovich normal cone to \( A \) at \( x^* \) are defined by
\[
TA(x^*) := \{ d \in \mathbb{R}^m \mid \exists t_k \downarrow 0, \, d_k \to d \text{ such that } x^* + t_k d_k \in A \},
\]
\[
\hat{N}A(x^*) := \{ \zeta \in \mathbb{R}^m \mid \langle \zeta, x - x^* \rangle \leq o(\|x - x^*\|) \quad \forall x \in A \},
\]
\[
N_A(x^*) := \{ \zeta \in \mathbb{R}^m \mid \exists \{x_k\} \subseteq A, \, \exists \zeta_k \text{ such that } x_k \to x^*, \, \zeta_k \to \zeta, \, \zeta_k \in \hat{N}A(x^*) \},
\]
respectively, see, e.g., [36]. When \( A \) is convex, all the normal cones above are equal and they coincide with the normal cone in the sense of convex analysis.

Using various normal cones, some stationary conditions were introduced; cf [11, Definition 1], [7, Definition 3].

**Definition 3.1** Let \( z^* \in \mathcal{F}_D \).

(a) We say that \( z^* \) is B-stationary (Bouligand stationary) if \( 0 \in \nabla f(z^*) + \hat{N}_{\mathcal{F}_D}(z^*) \).

(b) We say that \( z^* \) is S-stationary (Strongly stationary) if \( 0 \in \nabla f(z^*) + \nabla P(z^*)^T \hat{N}_A(P(z^*)) \).

(c) We say that \( z^* \) is M-stationary (Mordukhovich stationary) if \( 0 \in \nabla f(z^*) + \nabla P(z^*)^T N_A(P(z^*)) \).

**Definition 3.2** Let \( z^* \in \mathcal{F}_D \). We say that the generalized Guignard constraint qualification (GGCQ) holds at \( z^* \) if
\[
\hat{N}_{\mathcal{F}_D}(z^*) = (L_{\mathcal{F}_D}^{\text{lin}}(z^*))^\circ.
\]

GGCQ is a rather weak constraint qualification. For example, it holds if the set-valued map \( F(z) := -P(z) + \Lambda \) is metrically subregular at \( z^* \) (see Definition 3.8).

The following necessary optimality conditions are well known. Proposition 3.1(a) follows from the well-known fact that any local optimizer has no feasible descent directions and the fact that \( (T_{\mathcal{F}_D}(z^*))^\circ = \hat{N}_{\mathcal{F}_D}(z^*) \). Proposition 3.1(b) follows from (a) and the change of coordinates formula in [36, Exercise 6.7].

**Proposition 3.1** Let \( z^* \) be a local optimal solution of problem (5). Then,

(a) \( z^* \) is B-stationary.

(b) If \( \nabla P(z^*) \) has full rank \( m \), then \( z^* \) is S-stationary.

(c) [11, Theorem 7] Suppose GGCQ holds at \( z^* \). Then, \( z^* \) is M-stationary.
Recently, some MPDC-tailored versions of LICQ have been introduced in [30, Definition 3.1] and in [16, (31)] (see also Definition 4.5). These conditions all ensure that a local optimal solution is S-stationary.

It is easy to see that although B-stationary condition does not need any constraint qualification, it is implicit and hence not easy to use. S-stationary condition is sharper than M-stationary condition but requires very strong constraint qualification to hold. M-stationary condition is necessary for optimality under very weak constraint qualification, but it can be very weak for certain problems. Recently, some stationary conditions weaker than B-stationarity but stronger than M-stationarity have been introduced. We now review these results.

For problems in the form (5) but with \( \Lambda_1 \) being an arbitrary closed set, the limiting normal cone in M-stationary condition can be hard to compute and the resulting M-stationary condition can be weak. In order to deal with this difficulty, Gfrerer [15] introduced the so-called linearized M-stationary condition by a repeated linearization procedure. We now apply the linearization procedure to our problem. Suppose that \( z^* \) is B-stationary for problem (5) with \( \Lambda_1 \) being a closed set and GGCQ holds at \( z^* \). Then, since \(-\nabla f(z^*) \in \hat{N}_{FD}(z^*)\), by (6) the point \( d^* = 0 \) is a global minimizer for the linearized problem

\[
\min_d \nabla f(z^*)^T d \text{ s.t. } \nabla P(z^*)d \in T_\Lambda(P(z^*)).
\] (7)

If a constraint qualification holds, then M-stationary condition for the above linearized problem holds at \( d^* = 0 \). In our case, since \( \Lambda \) is the union of finitely many convex polyhedral sets, the perturbed feasible map \( \mathcal{F}_D(d) := \nabla P(z^*)d - T_\Lambda(P(z^*)) \) is metrically subregular at \((0, 0)\) and hence, GGCQ holds automatically. Then, by Proposition 3.1(c), \( d^* = 0 \) is an M-stationary point of the linearized problem which means that

\[
0 \in \nabla f(z^*) + \nabla P(z^*)^T N_{T_\Lambda(P(z^*))}(0).
\] (8)

The linearization procedure would continue if \( T_\Lambda(P(z^*)) \) is not the union of finitely many convex polyhedral sets, until a series of tangent cones to tangent cones to the set \( \Lambda \) is the union of finitely many convex polyhedral sets. The resulting optimality condition is called a linearized M-stationary condition. In general, the linearized M-stationary condition is sharper than M-stationary condition. To see this, suppose \( T_\Lambda(P(z^*)) \) is the union of finitely many convex polyhedral sets and the original set \( \Lambda \) is not. Then, the linearized M-stationary condition is (8). Since \( N_{T_\Lambda(P(z^*))}(0) \subseteq N_\Lambda(P(z^*)) \), cf. [36, Proposition 6.27], the linearized M-stationary condition is sharper than M-stationary condition. Moreover, \( N_{T_\Lambda(P(z^*))}(0) \) would be easier to calculate than the normal cone \( N_\Lambda(P(z^*)) \) in this case. But since in our case, \( \Lambda \) is the union of finitely many convex polyhedral sets, \( N_{T_\Lambda(P(z^*))}(0) = N_\Lambda(P(z^*)) \) (see [21, p. 59]). Hence, the linearized M-stationary condition coincides with M-stationary condition for the disjunctive program.

Another approach taken by Benko and Gfrerer in [7] to obtain sharper stationary condition than M-stationary condition for problems in the form (5) but with \( \Lambda \) being an arbitrary closed set is to give an accurate estimate for the regular normal cone to the constraint system. The idea is as follows. Let \( Q_1, Q_2 \subseteq T_\Lambda(P(z^*)) \) be two closed
convex cones. Then,
\[ \nabla P(z^*)^{-1} Q_i \subseteq \nabla P(z^*)^{-1} T \Lambda(P(z^*)) = L_{\mathcal{F}_D}^{\text{lin}}(z^*), \quad i = 1, 2, \]
where \( \nabla P(z^*)^{-1} Q_i := \{d | \nabla P(z^*) d \in Q_i \} \). Therefore, if GGCQ holds at \( z^* \), we have
\[ \hat{N}_{\mathcal{F}_D}(z^*) = (L_{\mathcal{F}_D}^{\text{lin}}(z^*))^\circ \]
\[ \subseteq (\nabla P(z^*)^{-1} Q_1 \cup \nabla P(z^*)^{-1} Q_2)^\circ \]
\[ = (\nabla P(z^*)^{-1} Q_1)^\circ \cap (\nabla P(z^*)^{-1} Q_2)^\circ \]
since \( Q_1 \) and \( Q_2 \) are convex cones.

Moreover, suppose the following condition holds:
\[ (\nabla P(z^*)^{-1} Q_i)^\circ = \nabla P(z^*)^T Q_i^\circ, i = 1, 2. \quad (9) \]
Then, it follows that
\[ \hat{N}_{\mathcal{F}_D}(z^*) \subseteq (\nabla P(z^*)^T Q_1^\circ) \cap (\nabla P(z^*)^T Q_2^\circ) \]
\[ = \nabla P(z^*)^T \left( Q_1^\circ \cap (\ker \nabla P(z^*)^T + Q_2^\circ) \right) , \quad (10) \]
where \( \ker \nabla P(z^*)^T := \{r | \nabla P(z^*)^T r = 0 \} \) and the equality follows from [7, Lemma 1]. The right hand side of the inclusion (10) gives an upper estimate for \( \hat{N}_{\mathcal{F}_D}(z^*) \). In order to have that the above inclusion provides a good estimate for the regular normal cone, it is obvious that we want to choose \( Q_1, Q_2 \) as large as possible so that the inclusion is tight. Furthermore, since one always has \( \nabla P(z^*)^T \hat{N}_{\Lambda}(P(z^*)) \subseteq \hat{N}_{\mathcal{F}_D}(z^*) \) ([36, Theorem 6.14]), if
\[ \nabla P(z^*)^T \left( Q_1^\circ \cap (\ker \nabla P(z^*)^T + Q_2^\circ) \right) \subseteq \nabla P(z^*)^T \hat{N}_{\Lambda}(P(z^*)), \quad (11) \]
then the equality holds in (10) and consequently,
\[ \hat{N}_{\mathcal{F}_D}(z^*) = \nabla P(z^*)^T \left( Q_1^\circ \cap (\ker \nabla P(z^*)^T + Q_2^\circ) \right) = \nabla P(z^*)^T \hat{N}_{\Lambda}(P(z^*)). \quad (12) \]

How to choose \( Q_1, Q_2 \) satisfying the condition (11)? One good choice is to find \( Q_1, Q_2 \) satisfying
\[ Q_1^\circ \cap Q_2^\circ = \hat{N}_{\Lambda}(P(z^*)), \]
since then condition (11) holds whenever \( \nabla P(z^*) \) has full rank.

Based on the estimates of the regular normal cone in (10) and the fact that any local minimizer is an B-stationary point, Benko and Gfrerer in [7] introduced the concept
of the so-called $Q$-stationarity. Moreover, when a $Q$-stationary point is also a M-
stationary point, then they call it a $Q_M$-stationary point. In our case, since $T_\Lambda(P(z^*))$
is the union of finitely many convex polyhedral sets, we can choose $Q_1, Q_2$ to be
closed convex polyhedral cones. By [7, Proposition 1], the polyhedrality of the cones
$Q_i \subseteq T_\Lambda(P(z^*)), i = 1, 2$ ensures validity of (9). We now give definition for $Q$-
stationarity for the disjunctive program.

**Definition 3.3** ([7, Definition 4 and Lemma 2]) Let $Q$ denote some collection of pairs
$(Q_1, Q_2)$ of closed convex polyhedral cones fulfilling $Q_i \subseteq T_\Lambda(P(z^*)), i = 1, 2$.

(i) Given $(Q_1, Q_2) \in Q$, we say that $z^*$ is $Q$-stationary with respect to $(Q_1, Q_2)$
for program (5) if

$$0 \in \nabla f(z^*) + \nabla P(z^*)^T \left( Q_1^T \cap (\ker P(z^*)^T + Q_2^T) \right).$$

(ii) We say that $z^*$ is $Q$-stationary for program (5), if $z^*$ is $Q$-stationary with respect
to some pair $(Q_1, Q_2) \in Q$.

(iii) We say that $z^*$ is $Q_M$-stationary provided that $z^*$ is both M-stationary and $Q$-
stationary with respect to some pair $(Q_1, Q_2) \in Q$, i.e., there exists a pair
$(Q_1, Q_2) \in Q$ such that

$$0 \in \nabla f(z^*) + \nabla P(z^*)^T \left( Q_1^T \cap (\ker P(z^*)^T + Q_2^T) \cap N_\Lambda(P(z^*)) \right).$$

Based on the discussion before Definition 3.3, we obtain the following optimality
conditions.

**Proposition 3.2** Let $z^*$ be a local optimal solution for program (5). If GGCQ holds
at $z^*$, then $z^*$ is $Q$-stationary with respect to every pair $(Q_1, Q_2) \in Q$. Moreover,
z* is $Q_M$-stationary with respect to every pair $(Q_1, Q_2) \in Q$. Conversely, if $z^*$ is
$Q$-stationary with respect to some pair $(Q_1, Q_2) \in Q$ fulfilling (11), then $z^*$ is S-
stationary and consequently also B-stationary.

**Proof** Let $z^*$ be a local optimal solution for program (5). Then, by Proposition 3.1,
z* is a B-stationary point, i.e., $-\nabla f(z^*) \in \bar{N}_{F_D}(z^*)$. If GGCQ holds at $z^*$, then by
(10) and Definition 3.3, $z^*$ is $Q$-stationary with respect to every pair $(Q_1, Q_2) \in Q$.
Moreover, by Proposition 3.1, it is also an M-stationary point and hence $Q_M$-stationary.
Conversely, suppose that $z^*$ is $Q$-stationary with respect to some pair $(Q_1, Q_2) \in Q$
fulfilling (11). Then, by definition of $Q$-stationarity and (12), $z^*$ is also S-stationary
and B-stationary. \[ \square \]

Now, we review the asymptotical version of M-stationarity. Using a simple penal-
ization argument, [29, Theorem 3.2] showed that any local minimizer $z^*$ of a very
general mathematical program

$$\min f(z) \text{ s.t. } 0 \in \Phi(z),$$ \hspace{1cm} (13)

where $f$ is Lipschitz continuous and $\Phi$ is a set-valued map, must be so-called AM-
stationary; see [29, Definition 3.1]. Setting $\Phi(z) := P(z) − \Lambda$ in [29, Definition
3.1] and using the coderivative sum rule as in [29, page 19], we may define the AM-stationarity for MPDC as follows.

**Definition 3.4** Let \( z^* \in \mathcal{F}_D \). We say that \( z^* \) is asymptotically M-stationary (AM-stationary) if there exist sequences \( \{z^k\}, \{\varepsilon^k\} \subseteq \mathbb{R}^n, \{y^k\} \subseteq \mathbb{R}^m \) with \( z^k \to z^*, \varepsilon^k \to 0 \) and \( y^k \to 0 \) such that

\[
\varepsilon^k \in \nabla f(z^k) + \nabla P(z^k)^T N_\Lambda(P(z^k) - y^k) \quad \forall k.
\]

The question is under what conditions is an AM-stationary point M-stationary? For problem (13), in [29, Definition 3.8], Mehlitz defined the so-called asymptotically Mordukhovich-regularity (AM-regularity for short) and showed that under AM-regularity, an AM-stationary point is M-stationary. Moreover, for the case of MPDC, according to the equivalence theorem shown in [29, Theorem 5.3], we can define AM-regularity as follows.

**Definition 3.5** [29, Theorem 5.3] Let \( z^* \in \mathcal{F}_D \). Define a set-valued mapping \( K : \mathbb{R}^n \rightrightarrows \mathbb{R}^n \) by means of

\[
K(z) := \nabla P(z)^T N_\Lambda(P(z^*)) \quad \forall z \in \mathbb{R}^n.
\]

We say that \( z^* \) is AM-regular if the following condition holds:

\[
\limsup_{z \to z^*} K(z) \subseteq K(z^*),
\]

where

\[
\limsup_{z \to z^*} K(z) := \{y \in \mathbb{R}^n | \exists z^k \to z^*, y^k \to y, \text{ s.t. } y^k \in K(z^k) \forall k\}.
\]

**Proposition 3.3** ([29, Theorem 3.2 and Theorem 3.9]) Let \( z^* \) be a local minimizer of MPDC. Then, \( z^* \) is AM-stationary. Moreover, suppose that \( z^* \) is AM-regular. Then, \( z^* \) is M-stationary.

Recently, the following directional version of the limiting normal cone was introduced.

**Definition 3.6** (directional normal cones) ([12, Definition 2] or [17, Definition 2.3]) Let \( A \subseteq \mathbb{R}^m \) be closed, \( x^* \in A \) and \( d \in \mathbb{R}^m \). The limiting normal cone to \( A \) at \( x^* \) in direction \( d \) is defined by

\[
N_A(x^*; d) := \left\{ \zeta \in \mathbb{R}^m | \exists t_k \downarrow 0, d^k \to d, \zeta^k \to \zeta, \text{ s.t. } \zeta^k \in \mathcal{N}_A(x^* + t_k d^k) \right\}.
\]

From the definition, it is obvious that the limiting normal cone to \( A \) at \( x^* \) in direction \( d = 0 \) is equal to the limiting normal cone. It is also easy to see that \( N_A(x^*, d) = \emptyset \) if
We say that the quasi-normality holds at \( a \), the following relationship holds \( \frac{d}{\lambda} \), the following relationship holds

\[
N_A(x^*; d) = N_A(x^*) \cap \{d\} \quad \forall d \in T_A(x^*).
\]

**Definition 3.7** ([40, Definition 3.3]) Let \( A \subseteq \mathbb{R}^m \) be closed, \( x^* \in A \) and \( d \in \mathbb{R}^m \). We say that set \( A \) is directionally regular at \( x^* \) if

\[
N_A(x^*; d) = N_A^i(x^*; d) \quad \forall d,
\]

where \( N_A^i(x^*; d) := \{ \xi \in \mathbb{R}^m | \forall t_k \downarrow 0, \exists d_k \to d, \xi_k \to \xi, \text{ s.t. } \xi_k \in \tilde{N}_A(x^* + t_k d_k) \} \).

If \( A \) is directionally regular at any point \( x \in A \), we say that the set \( A \) is directionally regular.

By [40, Proposition 3.5], any closed convex set is directionally regular. The following calculus rules will be useful. It is a special case of [40, Proposition 3.3].

**Proposition 3.4** ([40, Proposition 3.3]) Let \( A := A_1 \times A_2 \times \cdots \times A_l \), where \( A_i \subseteq \mathbb{R}^{m_i} \) is closed for \( i = 1, 2, \ldots, l \) and \( m = m_1 + m_2 + \cdots + m_l \). Consider a point \( x^* = (x^*_1, \ldots, x^*_l) \in A \) and a direction \( d = (d_1, \ldots, d_l) \in \mathbb{R}^m \). Moreover, suppose that all except at most one of \( A_i \) for \( i = 1, \ldots, l \) are directionally regular at \( x^*_i \), then

\[
T_A(x^*) = T_{A_1}(x^*_1) \times \cdots \times T_{A_l}(x^*_l), \quad N_A(x^*; d) = N_{A_1}(x^*_1; d_1) \times \cdots \times N_{A_l}(x^*_l; d_l).
\]

**Definition 3.8** (directional metric subregularity) ([12, Definition 2.1]) Let \( F(z) := P(z) - \Lambda \) be a set-valued map induced by \( P(z) \in \Lambda \). We say that the set-valued map \( F \) is metrically subregular in direction \( d \) at \((z^*, 0) \in \text{gph} F\), where \( \text{gph} F := \{(z, y) | y \in F(z)\} \) is the graph of \( F \), if there exist \( \kappa > 0 \) and \( \rho, \delta > 0 \) such that

\[
\text{dist}_{F^{-1}(0)}(z) \leq \kappa \text{dist}_{\Lambda}(P(z)), \quad \forall z \in z^* + \nu_{\rho, \delta}(d),
\]

where \( \nu_{\rho, \delta}(d) := \{z \in B_{\rho}(0)|\|d\| \leq \delta\|z\|\|d\|\} \) is the so-called directional neighborhood in direction \( d \), and \( F^{-1}(y) := \{z | y \in F(z)\} \) denotes the inverse of \( F \) at \( y \). If \( d = 0 \) in the above definition, then we say \( F \) is metrically subregular at \((z^*, 0)\).

According to [6], when the disjunctive set \( \Lambda := \bigcup_{i=1}^N \Lambda^l_i, \Lambda^l_i = \Pi_{i=1}^m [a^l_i, b^l_i] \), where \( a^l_i, b^l_i \) are given numbers with \( a^l_i \leq b^l_i \), with possibility of \( a^l_i = -\infty \) and \( b^l_i = +\infty \), we call (5) the ortho-disjunctive program. We now recall the following sufficient conditions for directional metric subregularity for the ortho-disjunctive program.

**Definition 3.9** Let \( z^* \) be a feasible solution to the ortho-disjunctive program.

(a) ([6, Corollary 5.1]) We say that the quasi-normality holds at \( z^* \) in direction \( d \in L_{f^D}(z^*) \) if there exists no \( \zeta \neq 0 \) such that

\[
0 = \nabla P(z^*)^T \zeta, \quad \zeta \in N_A(P(z^*); \nabla P(z^*)d),
\]

and

\[
\exists d_k \to d \quad t_k \downarrow 0 \text{ s.t. } \zeta_i(P_i(z^* + t_k d_k) - P_i(z^*)) > 0 \text{ if } \zeta_i \neq 0.
\]
We say that the directional quasi-normality holds at $z^*$ if the quasi-normality holds at $z^*$ in any direction $d \in L^\text{lin}_{\mathcal{F}_D}(z^*)$.

(b) ([6, Corollary 4.5]) We say that the pseudo-normality holds at $z^*$ in direction $d \in L^\text{lin}_{\mathcal{F}_D}(z^*)$ if there exists no $\zeta \neq 0$ such that (15) holds and

$$\exists d^k \rightarrow d \ s.t. \ (\zeta, P(z^* + t_k d^k) - P(z^*)) > 0.$$

We say that the directional pseudo-normality holds at $z^*$ if the pseudo-normality holds at $z^*$ in any direction $d \in L^\text{lin}_{\mathcal{F}_D}(z^*)$.

(c) ([13, Theorem 4.3]) We say that the first-order sufficient condition for metric subregularity (FOSCMS) holds at $z^*$ in direction $d \in L^\text{lin}_{\mathcal{F}_D}(z^*)$ if there exists no $\zeta \neq 0$ such that (15) holds.

(d) ([13, Theorem 4.3]) Suppose $P$ is second-order differentiable at $z^*$. We say that the second-order sufficient condition for metric subregularity (SOSCMS) holds at $z^*$ in direction $d \in L^\text{lin}_{\mathcal{F}_D}(z^*)$ if there exists no $\zeta \neq 0$ such that (15) and the following second-order condition hold

$$\sum_{i=1}^m \zeta_i d^T \nabla^2 P_i(z^*) d \geq 0.$$

Note that the concepts of directional quasi/pseudo-normality for the ortho-disjunctive program as defined in Definition 3.9 correspond precisely to the ones introduced for the general set-constrained optimization problem in [5]. It was shown in [6,13] that the following implications hold:

FOSCMS in $d \implies$ SOSCMS in $d \implies$ pseudo-normality in $d \implies$ quasi-normality in $d$.

We refer the reader to higher order sufficient condition for metric subregularity and other sufficient conditions for metric subregularity in [6].

The following result is a directional version of [5, Corollary 4.1].

**Proposition 3.5** ([5, Corollary 4.1]) Suppose that the quasi-normality holds at $z^*$ in $d \in L^\text{lin}_{\mathcal{F}_D}(z^*)$. Then, the set-valued map $F(z) := P(z) - \Lambda$ is metrically subregular at $(z^*, 0)$ in direction $d$.

We now summarize some first- and second-order necessary optimality conditions for MPDC in the following propositions.

**Proposition 3.6** ([14, Theorems 3.3]) Let $z^*$ be a local minimizer of problem (5) and $d \in \mathcal{C}(z^*)$, where $\mathcal{C}(z^*) := \{d \in L^\text{lin}_{\mathcal{F}_D}(z^*)|\nabla f(z^*)d \leq 0\}$ is the critical cone at $z^*$. If $F(z) := P(z) - \Lambda$ is metrically subregular at $(z^*, 0)$ in direction $d$, then $\mathcal{M}$-stationary condition in direction $d$ holds. That is, there exists $\zeta$ such that

$$0 = \nabla f(z^*) + \nabla P(z^*)^T \zeta, \quad \zeta \in N_{\mathcal{A}}(P(z^*); \nabla P(z^*)d). \quad (16)$$
Moreover, if $f$ and $P$ are twice differentiable at $z^*$, then there exists $\zeta$ satisfying (16) such that the second-order condition holds:

$$d^T \nabla^2 z \mathcal{L}(z^*, \zeta) d \geq 0,$$

where $\mathcal{L}(z, \zeta) := f(z) + P(z)^T \zeta$ is the Lagrangian.

We also give a sufficient optimality condition based on S-stationary condition below.

**Proposition 3.7** ([14, Theorems 3.3] or [30, Theorem 4.3]) Let $z^*$ be a feasible solution for problem (5) where $f$ and $P$ are twice differentiable at $z^*$. Suppose for each $0 \neq d \in C(z^*)$, there exists an S-multiplier $\zeta$ satisfying S-stationary condition

$$0 = \nabla f(z^*) + \nabla P(z^*)^T \zeta, \quad \zeta \in \hat{N}_\Lambda(P(z^*))$$

and the second-order condition

$$d^T \nabla^2 z \mathcal{L}(z^*, \zeta) d > 0.$$

Then, there is a constant $C > 0$ and $N(z^*)$ a neighborhood of $z^*$ such that the following quadratic growth condition is valid:

$$f(z) \geq f(z^*) + C\|z - z^*\|^2 \quad \forall z \in F_D \cap N(z^*).$$

In particular, $z^*$ is a strict local minimizer of MPDC.

**Definition 3.10** (see (31) in [16]) Let $d \in L^\text{lin}_D(z^*)$. We say that LICQ in direction $d$ (LICQ($d$)) holds at $z^*$ if

$$\nabla P(z^*)^T \lambda = 0, \quad \lambda \in \text{span}N_\Lambda(P(z^*); \nabla P(z^*)d) \Rightarrow \lambda = 0.$$

**Proposition 3.8** ([16, Lemma 7]) Let $z^*$ be a local minimizer of problem (5) and $d \in C(z^*)$. Suppose that LICQ($d$) holds. Then, S-stationary condition in direction $d$ holds. That is, there exists $\zeta$ such that

$$0 = \nabla f(z^*) + \nabla P(z^*)^T \zeta, \quad \zeta \in \hat{N}_{T_\Lambda(P(z^*))}(\nabla P(z^*)d). \quad (17)$$

Moreover, the multiplier $\zeta$ is unique.

### 4 Optimality Conditions for MPSC from the Corresponding Ones for MPDC

In this section, we reformulate MPSC as the following disjunctive program and derive the corresponding optimality conditions from Sect. 3.

$$\min f(z) \text{ s.t. } P(z) \in \Lambda, \quad (18)$$
where

\[
P(z) := (g(z), h(z), (G(z), H(z))), \quad \Lambda := \mathbb{R}^p_+ \times \{0\}^q \times \Omega^m_{SC}\]

with the switching cone

\[
\Omega_{SC} := \{(a, b) \in \mathbb{R}^2 | ab = 0\}.
\]

Since the switching cone \(\Omega_{SC}\) is the union of the two subspaces \(\mathbb{R} \times \{0\}\) and \(\{0\} \times \mathbb{R}\), the cone \(\Lambda\) is the union of \(2^m\) convex polyhedral sets.

By a straightforward calculation, we can obtain the formulas for various tangent and normal cones for the switching cone \(\Omega_{SC}\) defined in (20) as follows.

**Lemma 4.1** For all \(a = (a_1, a_2) \in \Omega_{SC}\), we have

\[
T_{\Omega_{SC}}(a) = \begin{cases} 
\{0\} \times \mathbb{R} & \text{if } a_1 = 0, a_2 \neq 0, \\
\Omega_{SC} & \text{if } a_1 = a_2 = 0, \\
\mathbb{R} \times \{0\} & \text{if } a_1 \neq 0, a_2 = 0
\end{cases},
\]

\[
\tilde{N}_{\Omega_{SC}}(a) = \begin{cases} 
\mathbb{R} \times \{0\} & \text{if } a_1 = 0, a_2 \neq 0, \\
\{0\} \times \mathbb{R} & \text{if } a_1 = a_2 = 0, \\
\{0\} \times \{0\} & \text{if } a_1 \neq 0, a_2 = 0
\end{cases},
\]

\[
N_{\Omega_{SC}}(a) = \begin{cases} 
\mathbb{R} \times \{0\} & \text{if } a_1 = 0, a_2 \neq 0, \\
\{0\} \times \mathbb{R} & \text{if } a_1 = a_2 = 0, \\
\{0\} \times \{0\} & \text{if } a_1 \neq 0, a_2 = 0
\end{cases},
\]

\[
\tilde{N}T_{\Omega_{SC}}(a)(d) = \begin{cases} 
\mathbb{R} \times \{0\} & \text{if } a_1 = 0, a_2 \neq 0, d_1 = 0, \\
\{0\} \times \mathbb{R} & \text{if } a_1 \neq 0, a_2 = 0, d_2 = 0, \\
\mathbb{R} \times \{0\} & \text{if } a_1 = a_2 = 0, d_1 = 0, d_2 \neq 0, \\
\{0\} \times \mathbb{R} & \text{if } a_1 = a_2 = 0, d_1 \neq 0, d_2 = 0, \\
\{0\} \times \{0\} & \text{if } a_1 \neq 0, a_2 = 0, d_1 = d_2 = 0
\end{cases},
\]

\[
N_{\Omega_{SC}}(a; d) = N_{\Omega_{SC}}^{ij}(a; d) = \begin{cases} 
\mathbb{R} \times \{0\} & \text{if } a_1 = 0, a_2 \neq 0, d_1 = 0, \\
\{0\} \times \mathbb{R} & \text{if } a_1 \neq 0, a_2 = 0, d_2 = 0, \\
\mathbb{R} \times \{0\} & \text{if } a_1 = a_2 = 0, d_1 = 0, d_2 \neq 0, \\
\{0\} \times \mathbb{R} & \text{if } a_1 = a_2 = 0, d_1 \neq 0, d_2 = 0, \\
\Omega_{SC} & \text{if } a_1 = a_2 = d_1 = d_2 = 0
\end{cases}.
\]

Hence, the switching cone \(\Omega_{SC}\) is directionally regular.

Since \(\mathbb{R}^p_+\) and \(\{0\}^q\) are obviously directionally regular and the switching cone \(\Omega_{SC}\) is directionally regular, the calculus rules for tangent and directional normal cones of \(\Lambda\) as a Cartesian product in Proposition 3.4 hold. Hence, for any \(z^*\) such that \(P(z^*) \in \Lambda\), we can obtain the expression for the tangent cone to \(\Lambda\) at \(P(z^*)\) as follows:

\[
T_{\Lambda}(P(z^*)) = T_{\mathbb{R}^p_+}(g(z^*)) \times T_{\{0\}^q}(0) \times \prod_{i=1}^m T_{\Omega_{SC}}(G_i(z^*), H_i(z^*)). \tag{21}
\]
First, we study $Q$ and $Q_M$ stationary conditions for MPSC. Let $\mathcal{P}(I_{GH}^\ast)$ be the set of all (disjoint) bipartitions of $I_{GH}^\ast$. For fixed $(\beta_1, \beta_2) \in \mathcal{P}(I_{GH}^\ast)$, we define the convex polyhedral cone

$$Q_{SC}^{\beta_1, \beta_2} := T_{\mathbb{R}^p}(g(z^*)) \times \{0\}^q \times \prod_{i=1}^m \tau_i^{\beta_1, \beta_2}$$

where $\tau_i^{\beta_1, \beta_2} := T_{\Omega_{SC}}(G_i(z^*), H_i(z^*))$ if $i \in I_G^\ast \cup I_H^\ast$ and

$$\tau_i^{\beta_1, \beta_2} := \begin{cases} \{0\} \times \mathbb{R} & \text{if } i \in \beta_1, \\ \mathbb{R} \times \{0\} & \text{if } i \in \beta_2. \end{cases}$$

By (21) and the formula for the tangent cone to $\Omega_{SC}$ in Lemma 4.1, it is easy to see that $Q_{SC}^{\beta_1, \beta_2}$ is a subset of $T_\Lambda(P(z^*))$ as required by $Q$-stationarity. Moreover, similarly to [7, Lemma 3], we can show that for any $(\beta_1, \beta_2) \in \mathcal{P}(I_{GH}^\ast)$,

$$(Q_{SC}^{\beta_1, \beta_2})^\circ \cap (Q_{SC}^{\beta_2, \beta_1})^\circ = \overline{N_\Lambda}(P(z^*)).$$

Hence, according to the discussion in Sect. 3, $Q_1 := Q_{SC}^{\beta_1, \beta_2}, Q_2 := Q_{SC}^{\beta_2, \beta_1}$ would be a good choice for the $Q$-stationarity. Similar to [7, Proposition 4], we can derive the definition of $Q$-stationarity for MPSC by using the corresponding definitions for the disjunctive program in Definition 3.3. By Definition 3.3, $z^*$ is $Q$-stationary with respect to $(Q_{SC}^{\beta_1, \beta_2}, Q_{SC}^{\beta_2, \beta_1})$ if

$$-\nabla f(z^*) \in \nabla P(z^*)^T \left((Q_{SC}^{\beta_1, \beta_2})^\circ \cap (\ker \nabla P(z^*)^T + (Q_{SC}^{\beta_2, \beta_1})^\circ)\right)$$

$$= \left\{ \sum_{i=1}^p \lambda_i^G \nabla g_i(z^*) + \sum_{i=1}^q \lambda_i^H \nabla h_i(z^*) + \sum_{i=1}^m \left(\lambda_i^G \nabla G_i(z^*) + \lambda_i^H \nabla H_i(z^*)\right) \right\} \in (Q_{SC}^{\beta_1, \beta_2})^\circ \cap (\ker \nabla P(z^*)^T + (Q_{SC}^{\beta_2, \beta_1})^\circ).$$

Next, we are aiming to find a formula for $(Q_{SC}^{\beta_1, \beta_2})^\circ \cap (\ker \nabla P(z^*)^T + (Q_{SC}^{\beta_2, \beta_1})^\circ)$ in the above. Obviously, we have $(Q_{SC}^{\beta_1, \beta_2})^\circ = N_{\mathbb{R}^p}(g(z^*)) \times \mathbb{R}^q \times \prod_{i=1}^m \tau_i^{\beta_1, \beta_2}$ and the set $(Q_{SC}^{\beta_1, \beta_2})^\circ \cap (\ker \nabla P(z^*)^T + (Q_{SC}^{\beta_2, \beta_1})^\circ)$ consists of all $\lambda = (\lambda^h, \lambda^g, \lambda^G, \lambda^H)$ such that there exists $\mu = (\mu^h, \mu^g, \mu^G, \mu^H) \in \ker \nabla P(z^*)^T$ and $$(\eta^h, \eta^g, \eta^G, \eta^H) \in (Q_{SC}^{\beta_2, \beta_1})^\circ = N_{\mathbb{R}^p}(g(z^*)) \times \mathbb{R}^q \times \prod_{i=1}^m \tau_i^{\beta_2, \beta_1}$$ such that

$$\lambda = \mu + \eta \in (Q_{SC}^{\beta_1, \beta_2})^\circ.$$

We now analyze the following different cases:

- Equality constraints: We obtain $\lambda^h = \mu^h + \eta^h \in \mathbb{R}^q, \eta^h \in \mathbb{R}^q$, i.e., $\lambda^h, \mu^h \in \mathbb{R}^q$. 

\[\square\] Springer
• Inequality constraints: For \( i \in T_g^* \), we have \( \lambda^g_i = \mu^g_i + \eta^g_i \geq 0, \eta^g_i \geq 0 \) or equivalently \( \lambda^g_i \geq \max(0, \mu^g_i) \), whereas for \( i \in \{1, \ldots, p\} \setminus T_g^* \), we obtain \( \lambda^g_i = \mu^g_i = 0 \).
• \( i \in T_H^* \): Since \( (\tau^{\beta_1, \beta_2}_i)^o = \mathbb{R} \times \{0\} \), we obtain \( \lambda^H_i = \eta^H_i = 0 \) and so \( \mu^H_i = 0 \).
• \( i \in T_H \): Similarly as in the previous case, we obtain \( \lambda^G_i = \mu^G_i = 0 \).
• \( i \in \beta_1 \): Since \( (\tau^{\beta_1}_i, \beta^{\beta_2}_i)^o = \mathbb{R} \times \{0\} \) and \( (\tau^{\beta_2}_i, \beta_2)^o = \{0\} \times \mathbb{R} \), we have
\[
(\lambda^G_i, \lambda^H_i) = (\mu^G_i, \mu^H_i) + (\eta^G_i, \eta^H_i) \in \mathbb{R} \times \{0\}
\]
and \( (\eta^G_i, \eta^H_i) \in \{0\} \times \mathbb{R} \). Equivalently, we obtain \( \lambda^H_i = 0 \) and \( \lambda^G_i = \mu^G_i \).
• \( i \in \beta_2 \): Similarly as in the previous case, we obtain \( \lambda^G_i = 0 \) and \( \lambda^H_i = \mu^H_i \).

We now denote two multiplier sets
\[
\mathcal{R}_{SC} := \{ (\mu^g, \mu^h, \mu^G, \mu^H) \in \mathbb{R}^p \times \mathbb{R}^q \times \mathbb{R}^m \times \mathbb{R}^m | \mu^g_i = 0, i = \{1, \ldots, p\} \setminus T_g^* \},
\]
\[
\mu^G_i = 0, i \in T_H^*, \mu^H_i = 0, i \in T_G^* \}
\]
and
\[
\mathcal{N}_{SC} := \left\{ (\mu^g, \mu^h, \mu^G, \mu^H) \in \mathcal{R}_{SC} \left| \sum_{i=1}^p \mu^g_i \nabla g_i(z^*) + \sum_{i=1}^q \mu^h_i \nabla h_i(z^*) + \sum_{i=1}^m \mu^G_i \nabla G_i(z^*) + \mu^H_i \nabla H_i(z^*) = 0 \right. \right\}.
\]

Based on the discussion above, we can now give the following definition.

**Definition 4.1** Let \( z^* \in \mathcal{F} \). We say that \( z^* \) is \( Q \)-stationary for MPSC (2) with respect to \( (\beta_1, \beta_2) \in \mathcal{P}(T_{GH}^*) \) if there exists multipliers \( (\lambda^g, \lambda^h, \lambda^G, \lambda^H) \in \mathcal{R}_{SC} \) such that
\[
0 = \nabla f(z^*) + \sum_{i=1}^p \lambda^g_i \nabla g_i(z^*) + \sum_{i=1}^q \lambda^h_i \nabla h_i(z^*) + \sum_{i=1}^m \lambda^G_i \nabla G_i(z^*) + \lambda^H_i \nabla H_i(z^*)
\]
and \( (\mu^g, \mu^h, \mu^G, \mu^H) \in \mathcal{N}_{SC} \) such that
\[
\lambda^g_i \geq \max(\mu^g_i, 0), i \in T_g^*, \lambda^H_i = 0, \lambda^G_i = \mu^G_i, i \in \beta_1, \lambda^G_i = 0, \lambda^H_i = \mu^H_i, i \in \beta_2.
\]

It is easy to see that for MPSC, a \( Q \)-stationary point is also an M-stationary point. Hence, for MPSC, \( Q \)-stationary condition coincides with \( Q_M \)-stationary condition.

Applying Proposition 3.2, similar to [7, Proposition 4 and Theorem 5], we have the following optimality conditions.

**Proposition 4.1** Let \( z^* \) be a local optimal solution for MPSC. If \( GGCQ \) holds at \( z^* \), then \( z^* \) is \( Q \)-stationary with respect to every pair \( (\beta_1, \beta_2) \in \mathcal{P}(T_{GH}^*) \). Conversely, if...
$z^*$ is $Q$-stationary with respect to some pair $(\beta_1, \beta_2) \in \mathcal{P}(\mathcal{I}_{GH}^*)$ such that for every $\mu \in \mathcal{N}_{SC}$ there holds

$$
\mu_i^G \mu_i^G = 0, \mu_i^H \mu_i^H = 0 \quad \forall (i, i') \in \beta_1 \times \beta_2, \tag{22}$$
$$
\mu_i^G \mu_i^H = 0 \quad \forall (i, i') \in \beta_1 \times \beta_1, \tag{23}$$
$$
\mu_i^G \mu_i^H = 0 \quad \forall (i, i') \in \beta_2 \times \beta_2. \tag{24}
$$

Then, $z^*$ is $S$-stationary.

**Proof** The first statement follows directly from Proposition 3.2. We now prove the converse statement. Suppose that $z^*$ is $Q$-stationary with respect to some pair $(\beta_1, \beta_2) \in \mathcal{P}(\mathcal{I}_{GH}^*)$. Then by definition, there exist $(\lambda^g, \lambda^h, \lambda^G, \lambda^H) \in \mathcal{R}_{SC}$ and $(\mu^g, \mu^h, \mu^G, \mu^H) \in \mathcal{N}_{SC}$ satisfying the $Q$-stationarity condition. Since by the definition of $Q$-stationarity, $\lambda_i^H = 0, i \in \beta_1$ and $\lambda_i^G = 0, i \in \beta_2$. So if $\lambda_i^G = 0, i \in \beta_1$ and $\lambda_i^H = 0, i \in \beta_2$, then $z^*$ must be $S$-stationary in this case. Otherwise, either there is some $j \in \beta_1$ such that $\lambda_j^G \neq 0$ or some $j \in \beta_2$ such that $\lambda_j^H \neq 0$.

First, consider the case when $\lambda_j^G \neq 0$ for some $j \in \beta_1$. Set $(\tilde{\lambda}^g, \tilde{\lambda}^h, \tilde{\lambda}^G, \tilde{\lambda}^H) := (\lambda^g - \mu^g, \lambda^h - \mu^h, \lambda^G - \mu^G, \lambda^H - \mu^H)$. Then,

$$
0 = \nabla f(z^*) + \sum_{i=1}^p \tilde{g}_i^G \nabla g_i(z^*) + \sum_{i=1}^q \tilde{h}_i^G \nabla h_i(z^*) + \sum_{i=1}^m (\tilde{\lambda}_i^G \nabla G_i(z^*) + \tilde{\lambda}_i^H \nabla H_i(z^*))
$$

and

$$
\tilde{\lambda}_i^g = 0, i \notin \mathcal{I}_g^*, \tilde{\lambda}_i^g \geq 0, i \in \mathcal{I}_g^*, \tilde{\lambda}_i^G = 0, i \in \mathcal{I}_G^*, \tilde{\lambda}_i^H = 0, i \in \mathcal{I}_H^*,
$$

Further, since $0 \neq \lambda^G_j = \mu^G_j$, then by (22) we have $\mu_i^G = 0 \forall i \in \beta_2$ and by (23) we have $\mu_i^H = 0 \forall i \in \beta_1$. Consequently, $\tilde{\lambda}_i^G = 0$, and $\tilde{\lambda}_i^H = 0$ holds for all $i \in \beta_1 \cup \beta_2$. Hence, $z^*$ is $S$-stationary. The proof for the case when $\lambda_i^H \neq 0$ for some $j \in \beta_2$ is similar and (22) and (24) are used to derive the result in this case. \hfill $\square$

Applying Definition 3.4 and Lemma 4.1, we have the following AM-stationary condition for MPSC. Let $z^* \in \mathcal{F}$. AM-stationary condition for MPSC holds at $z^*$ if there exist sequences $\{z^k\} \subseteq \mathbb{R}^n, \{\varepsilon^k\} \subseteq \mathbb{R}^n, \{(y^g^k, y^h^k, y^G^k, y^H^k)\} \subseteq \mathbb{R}^q \times \mathbb{R}^q$ and multipliers $\{\lambda^g, \lambda^h, \lambda^G, \lambda^H\} \subseteq \mathbb{R}^p \times \mathbb{R}^q \times \mathbb{R}^m \times \mathbb{R}^m$ with $\varepsilon^k \to 0, z^k \to z^*, (y^g^k, y^h^k, y^G^k, y^H^k) \to 0$ such that $P(z^k) - y^k \in \Lambda$ and

$$
\nabla f(z^k) + \sum_{i=1}^p \lambda^g_i \nabla g_i(z^k) + \sum_{i=1}^q \lambda^h_i \nabla h_i(z^k)
$$

$$
+ \sum_{i=1}^m (\lambda^G_i \nabla G_i(z^k) + \lambda^H_i \nabla H_i(z^k)) = \varepsilon^k.
$$
\[ \lambda_{i}^{g,k} = 0, \text{ if } g_{i}(z^{k}) - y_{i}^{g,k} < 0; \quad \lambda_{i}^{g,k} \geq 0 \text{ if } g_{i}(z^{k}) - y_{i}^{g,k} = 0, \quad (25) \]
\[ \lambda_{i}^{G,k} = 0, \text{ if } G_{i}(z^{k}) - y_{i}^{G,k} \neq 0, H_{i}(z^{k}) - y_{i}^{H,k} = 0, \quad (26) \]
\[ \lambda_{i}^{H,k} = 0, \text{ if } G_{i}(z^{k}) - y_{i}^{G,k} = 0, H_{i}(z^{k}) - y_{i}^{H,k} \neq 0, \quad (27) \]
\[ \lambda_{i}^{G,k}, \lambda_{i}^{H,k} = 0, \text{ if } G_{i}(z^{k}) - y_{i}^{G,k} = H_{i}(z^{k}) - y_{i}^{H,k} = 0. \quad (28) \]

Using the following arguments, the dummy sequences \( \{y^{k}\} \) and \( \{\varepsilon^{k}\} \) can be deleted.

- Let \( i \notin T_{g}^{*} \). Then, for \( k \) large enough \( g_{i}(z^{k}) < 0 \), which implies that \( g_{i}(z^{k}) - y_{i}^{g,k} < 0 \) for \( k \) large enough. By (25), we have \( \lim_{k \to \infty} \min \{\lambda_{i}^{g,k}, -g_{i}(z^{k})\} = 0 \).
- Let \( i \in T_{g}^{*} \). Since \( \min \{\lambda_{i}^{g,k}, -g_{i}(z^{k})\} \leq -g_{i}(z^{k}) \) and \( g_{i}(z^{k}) \to 0 \), we have \( \lim_{k \to \infty} \min \{\lambda_{i}^{g,k}, -g_{i}(z^{k})\} = 0 \).
- Let \( i \in T_{G}^{H} \). Similarly, we have \( \lim_{k \to \infty} \min \{|\lambda_{i}^{G,k}|, |G_{i}(z^{k})|\} = 0 \) and \( \lim_{k \to \infty} \min \{|\lambda_{i}^{H,k}|, |H_{i}(z^{k})|\} = 0 \).
- Let \( i \in T_{G}^{*} \). Then, we have \( \lim_{k \to \infty} \min \{\lambda_{i}^{G,k}, |G_{i}(z^{k})|\} = 0 \). Moreover, since \( H_{i}(z^{*}) \neq 0 \), we have that for \( k \) large enough \( H_{i}(z^{k}) \neq 0 \), which implies that \( H_{i}(z^{k}) - y_{i}^{H,k} \neq 0 \) for \( k \) large enough. Then, by (27), we have that for \( k \) large enough \( \lambda_{i}^{H,k} = 0 \) and hence \( \lim_{k \to \infty} \min \{|\lambda_{i}^{H,k}|, |H_{i}(z^{k})|\} = 0 \) as well.
- Let \( i \in T_{H}^{*} \). This case is symmetric to the case above.
- For \( i = 1, \ldots, m \) and for all \( k \), since \((G_{i}(z^{k}), H_{i}(z^{k})) - (y_{i}^{G,k}, y_{i}^{H,k}) \in \Omega_{SC} \), by (26)-(28), we have \( \lambda_{i}^{G,k}, \lambda_{i}^{H,k} = 0 \).

By the above discussion, we give the following AM-stationarity for MPSC.

**Definition 4.2** Let \( z^{*} \in \mathcal{F} \). We say that \( z^{*} \) is AM-stationary for MPSC if and only if there exist sequences \( \{z^{k}\} \subseteq \mathbb{R}^{p} \) with \( \lim_{k \to \infty} z^{k} = z^{*} \) and multipliers \( \{(\lambda_{i}^{g,k}, \lambda_{i}^{h,k}, \lambda_{i}^{G,k}, \lambda_{i}^{H,k})\} \subseteq \mathbb{R}^{p} \times \mathbb{R}^{q} \times \mathbb{R}^{m} \times \mathbb{R}^{m} \) such that

\[
\lim_{k \to \infty} \|\nabla f(z^{k}) + \sum_{i=1}^{p} \lambda_{i}^{g,k} \nabla g_{i}(z^{k}) + \sum_{i=1}^{q} \lambda_{i}^{h,k} \nabla h_{i}(z^{k}) + \sum_{i=1}^{m} (\lambda_{i}^{G,k} \nabla G_{i}(z^{k}) + \lambda_{i}^{H,k} \nabla H_{i}(z^{k}))\| = 0,
\]

\[
\lim_{k \to \infty} \min \{\lambda_{i}^{g,k}, -g_{i}(z^{k})\} = 0, \quad i = 1, \ldots, p,
\]

\[
\lambda_{i}^{G,k}, \lambda_{i}^{H,k} = 0 \quad \forall k, i = 1, \ldots, m,
\]

\[
\lim_{k \to \infty} \min \{|\lambda_{i}^{G,k}|, |G_{i}(z^{k})|\} = 0, \quad \lim_{k \to \infty} \min \{|\lambda_{i}^{H,k}|, |H_{i}(z^{k})|\} = 0, \quad i = 1, \ldots, m.
\]

Applying Definition 3.5 and Lemma 4.1, we have the following AM-regularity for MPSC.
Lemma 4.1, the linearization cone of the feasible region.

\[ z \]

We say that \( K \)

Definition 4.3

Theorem 4.1

Applying Proposition 3.3, we have the following conclusion.

We say that \( z^* \) is AM-regular if the following condition holds:

Applying Proposition 3.3, we have the following conclusion.

**Theorem 4.1** Let \( z^* \) be a local minimizer of MPSC, then \( z^* \) is AM-stationary. Moreover, suppose that \( z^* \) is AM-regular. Then, \( z^* \) is M-stationary.

We now apply Propositions 3.6 and 3.8 to MPSC in the form of (18). By the expressions for \( T_\Lambda(P(z^*)) \) in (21) and the expression for the tangent cone of the switching set in Lemma 4.1, the linearization cone of the feasible region \( F \) can be expressed as follows:

\[
L^\text{lin}_{F}(z^*) := \left\{ d | \nabla P(z^*)d \in T_\Lambda(P(z^*)) \right\}
\]

Denote the critical cone at \( z^* \) by \( C_{F}(z^*) := \{ d \in L^\text{lin}_{F}(z^*) | \nabla f(z^*)d \leq 0 \} \). Given \( d \in L^\text{lin}_{F}(z^*) \), we define

Then, by the Cartesian product rule in Proposition 3.4, the expressions for the tangent cone and the directional limiting normal cone to the switching cone in Lemma 4.1 we have,

\[
N_{\Lambda}(P(z^*); \nabla P(z^*)d) = N_{R^p}(g(z^*); \nabla g(z^*)d) \times N_{[0]^q}(h(z^*); \nabla h(z^*)d)
\]

\[
\times \Pi_{i=1}^m N_{\Omega_{SC}}((G_i(z^*), H_i(z^*)); (\nabla G_i(z^*)d, \nabla H_i(z^*)d)),
\]

with

\[
N_{\Omega_{SC}}((G_i(z^*), H_i(z^*)); (\nabla G_i(z^*)d, \nabla H_i(z^*)d))
\]
Based on the directional M-stationary condition (16) and directional S-stationary condition (17), we now define the directional version of the W, S, M-stationarity for MPSC.

**Definition 4.4** Let \( z^* \) be a feasible solution of MPSC and \( d \in C_F(z^*) \). We say that \( z^* \) is a W-stationary point of MPSC (2) in direction \( d \) if there exists \( (\lambda^g, \lambda^h, \lambda^G, \lambda^H) \) such that

\[
0 = \nabla f(z^*) + \sum_{i \in \mathcal{I}^*_g(d)} \lambda^g_i \nabla g_i(z^*)
\]

\[
+ \sum_{i=1}^q \lambda^h_i \nabla h_i(z^*) + \sum_{i=1}^m (\lambda^G_i \nabla G_i(z^*) + \lambda^H_i \nabla H_i(z^*))
\]

\[
\lambda^g_i \geq 0, \quad i \in \mathcal{I}^*_g(d), \quad \lambda^g_i = 0, \quad i \notin \mathcal{I}^*_g(d),
\]

\[
\lambda^G_i = 0, \quad i \in \mathcal{I}^*_H \cup \mathcal{I}^*_H(d), \quad \lambda^H_i = 0, \quad i \in \mathcal{I}^*_G \cup \mathcal{I}^*_G(d),
\]

\[
\lambda^G_i \lambda^H_i = 0, \quad i \in \mathcal{I}^*_G H(d).
\]

(29)

We say that \( z^* \) is a M-stationary point of MPSC (2) in direction \( d \) if there exists \( (\lambda^g, \lambda^h, \lambda^G, \lambda^H) \) such that (30)–(31) hold and \( \lambda^G_i \lambda^H_i = 0, \quad i \in \mathcal{I}^*_G H(d) \).

We say that \( z^* \) is an S-stationary point of MPSC (2) in direction \( d \) if there exists \( (\lambda^g, \lambda^h, \lambda^G, \lambda^H) \) such that (30)–(31) hold and \( \lambda^G_i = \lambda^H_i = 0, \quad i \in \mathcal{I}^*_G H(d) \).

Using the formula in (29), we have

\[
\text{span} N_A(P(z^*); \nabla P(z^*) d) = \left\{ (\lambda^g, \lambda^h, \lambda^G, \lambda^H) \middle| \begin{array}{l}
\lambda^g_i = 0, \quad i \notin \mathcal{I}^*_g(d), \\
\lambda^G_i = 0, \quad i \in \mathcal{I}^*_G \cup \mathcal{I}^*_H(d), \\
\lambda^H_i = 0, \quad i \in \mathcal{I}^*_G \cup \mathcal{I}^*_G(d)
\end{array} \right\}.
\]

Hence, based on Definition 3.10, we define the following directional version of the MPSC-LICQ.

\( \square \) Springer
Definition 4.5 Let $z^*$ be a feasible solution of MPSC (2) and $d \in L_{\text{lin}}^{\text{in}}(z^*)$. We say that the MPSC-LICQ in direction $d$ (MPSC-LICQ($d$)) holds at $z^*$ if and only if the gradients

\[
\{\nabla g_i(z^*)|i \in \mathcal{I}_g^*(d)\} \cup \{\nabla h_i(z^*)|i = 1, 2, \cdots, q\} \cup \{\nabla G_i(z^*)|i \in \mathcal{I}_G^* \cup \mathcal{I}_G^*(d) \cup \mathcal{I}_{GH}^*(d)\} \\
\cup \{\nabla H_i(z^*)|i \in \mathcal{I}_H^* \cup \mathcal{I}_H^*(d) \cup \mathcal{I}_{GH}^*(d)\}
\]

are linearly independent.

Since $\mathcal{I}_g^*(0) = \mathcal{I}_g^*, \mathcal{I}_G^*(0) = \mathcal{I}_H^*(0) = \emptyset$ and $\mathcal{I}_{GH}^*(0) = \mathcal{I}_{GH}^*$, MPSC-LICQ(0) is exactly the MPSC-LICQ.

Since MPSC is obviously an ortho-disjunctive program, by Definition 3.9, the directional quasi-/pseudo-normality for constraint system of MPSC (2) can be rewritten in the following form.

Definition 4.6 Let $z^*$ be a feasible solution of MPSC (2). We say that $z^*$ is MPSC quasi- or pseudo-normal in direction $d \in L_{\text{lin}}^{\text{in}}(z^*)$ if there exists no $(\lambda^g, \lambda^h, \lambda^G, \lambda^H) \neq 0$ such that

(i) \quad $0 = \nabla g(z^*)^T \lambda^g + \nabla h(z^*)^T \lambda^h + \nabla G(z^*)^T \lambda^G + \nabla H(z^*)^T \lambda^H$;

(ii) \quad $\lambda^g_i \geq 0, i \in \mathcal{I}_g^*(d); \lambda^g_i = 0, i \notin \mathcal{I}_g^*(d); \lambda^H_i = 0, i \in \mathcal{I}_G^* \cup \mathcal{I}_G^*(d); \lambda^G_i = 0, i \in \mathcal{I}_H^* \cup \mathcal{I}_H^*(d);$

(iii) \quad $\exists d^k \rightarrow d$ and $t_k \downarrow 0$ such that

\[
\begin{align*}
\lambda^g_i g_i(z^* + t_k d^k) &> 0, \text{ if } \lambda^g_i \neq 0, \\
\lambda^h_i h_i(z^* + t_k d^k) &> 0, \text{ if } \lambda^h_i \neq 0, \\
\lambda^G_i G_i(z^* + t_k d^k) &> 0, \text{ if } \lambda^G_i \neq 0, \\
\lambda^H_i H_i(z^* + t_k d^k) &> 0, \text{ if } \lambda^H_i \neq 0,
\end{align*}
\]

or

\[
\lambda^g T g(z^* + t_k d^k) + \lambda^h T h(z^* + t_k d^k) + \lambda^G T G(z^* + t_k d^k) + \lambda^H T H(z^* + t_k d^k) > 0,
\]

respectively.

We say that $z^*$ is directionally quasi- or pseudo-normal if it is quasi- or pseudo-normal in all directions from $L_{\text{lin}}^{\text{in}}(z^*)$.

Note that MPSC quasi-/pseudo-normality in direction $d = 0$ coincides with MPSC quasi-/pseudo-normality defined as in [26] and when $d \neq 0$, the directional one is weaker.

We now apply Definition 3.9 to obtain FOSCMS/SOSCMS for MPSC.

Definition 4.7 Let $z^*$ be a feasible solution of MPSC (2) and $d \in L_{\text{lin}}^{\text{in}}(z^*)$. We say that MPSC first-order sufficient condition for metric subregularity (MPSC-FOSCMS) in direction $d$ holds at $z^*$ if there exists no $(\lambda^g, \lambda^h, \lambda^G, \lambda^H) \neq 0$ such that (i)–(ii) in Definition 4.6 holds.
Note that MPSC-FOSCMS in direction \( d = 0 \) coincides with the MPSC-NNAMCQ defined as in [31] and when \( d \neq 0 \), MPSC-FOSCMS is weaker than MPSC-NNAMCQ.

**Definition 4.8** Let \( z^* \) be a feasible solution of MPSC (2) and \( d \in L_g^0(z^*) \). We say that MPSC second-order sufficient condition for metric subregularity (MPSC-SOSCMS) in direction \( d \) holds at \( z^* \) if there exists no \((\lambda^g, \lambda^h, \lambda^G, \lambda^H) \neq 0 \) such that (i)–(ii) in Definition 4.6 hold and

\[
d^T \nabla^2 L^0(z^*, \lambda^g, \lambda^h, \lambda^G, \lambda^H) d \geq 0,
\]

where \( L^0(z, \lambda^g, \lambda^h, \lambda^G, \lambda^H) := \langle \lambda^g, g(z) \rangle + \langle \lambda^h, h(z) \rangle + \langle \lambda^G, G(z) \rangle + \langle \lambda^H, H(z) \rangle \).

The following result follows from Propositions 3.6-3.8. The reader is referred to Fig. 3 for sufficient conditions for MPSC quasi-normality.

**Theorem 4.2** Let \( z^* \) be a local minimizer for MPSC (2) and let \( d \in C_d(z^*) \). If MPSC-LICQ(d) holds, then \( z^* \) is an S-stationary point in direction \( d \). If MPSC quasi-normality holds at \( z^* \) in direction \( d \), then \( z^* \) is an M-stationary point in direction \( d \). If \( f \) and \( F \) are twice differentiable at \( z^* \), then there exist an M-multiplier in direction \( d \) denoted by \((\lambda^g, \lambda^h, \lambda^G, \lambda^H) \) such that the second-order condition holds:

\[
d^T \nabla^2 L(z^*, \lambda^g, \lambda^h, \lambda^G, \lambda^H) d \geq 0,
\]

where \( L(z, \lambda^g, \lambda^h, \lambda^G, \lambda^H) := f(z) + \langle \lambda^g, g(z) \rangle + \langle \lambda^h, h(z) \rangle + \langle \lambda^G, G(z) \rangle + \langle \lambda^H, H(z) \rangle \). Conversely, suppose that \( z^* \) is a feasible solution to MPSC and for each \( 0 \neq d \in C_d(z^*) \), there is an S-multiplier denoted by \((\lambda^g, \lambda^h, \lambda^G, \lambda^H) \) and the second-order condition

\[
d^T \nabla^2 L(z^*, \lambda^g, \lambda^h, \lambda^G, \lambda^H) d > 0
\]

holds, then \( z^* \) is a strict local minimizer of MPSC.

For MPEC, Gfrerer [14] pointed out that the extended M-stationary condition (which means the directional M-stationary condition holds at every critical direction) is usually hard to verify and introduced the strong M-stationary condition to build a bridge between M-stationarity and S-stationarity. Similarly, we can propose a concept of strong M-stationary condition in a critical direction. In what follows, we denote by \( r(z^*; d) \) the rank of the family of gradients

\[
\{\nabla g_i(z^*)|i \in \mathcal{I}_g^s(d)\} \cup \{\nabla h_i(z^*)|i = 1, \cdots, q\} \cup \{\nabla G_i(z^*)|i \in \mathcal{I}_G^s \cup \mathcal{I}_G^h \cup \mathcal{I}_{GH}(d)\} \\
\cup \{\nabla H_i(z^*)|i \in \mathcal{I}_H^s \cup \mathcal{I}_H^h \cup \mathcal{I}_{GH}(d)\}.
\]

**Definition 4.9** A triple of index sets \((\mathcal{J}_g, \mathcal{J}_G, \mathcal{J}_H)\) with \( \mathcal{J}_g \subseteq \mathcal{I}_g^s(d) \), \( \mathcal{J}_G \subseteq \mathcal{I}_G^s \cup \mathcal{I}_G^h \cup \mathcal{I}_{GH}(d) \), \( \mathcal{J}_H \subseteq \mathcal{I}_H^s \cup \mathcal{I}_H^h \cup \mathcal{I}_{GH}(d) \) is called an MPSC working set in direction \( d \) for MPSC (2), if \( \mathcal{J}_G \cup \mathcal{J}_H = \{1, 2, \cdots, m\} \),

\[
|\mathcal{J}_g| + q + |\mathcal{J}_G| + |\mathcal{J}_H| = r(z^*; d),
\]
and the family of gradients
\[ \{\nabla g_i(z^*)|i \in J_g\} \cup \{\nabla h_i(z^*)|i = 1, \ldots , q\} \cup \{\nabla G_i(z^*)|i \in J_G\} \cup \{\nabla H_i(z^*)|i \in J_H\} \]

is linearly independent.

The point \( z^* \) is called strongly M-stationary in direction \( d \) for MPSC (2), if there exists an MPSC working set \( (J_g, J_G, J_H) \) in direction \( d \) together with \( \lambda = (\lambda^g, \lambda^h, \lambda^G, \lambda^H) \), an M-multiplier in direction \( d \), satisfying
\[
\begin{align*}
\lambda^g_i &= 0, i \in \{1, \ldots , p\} \setminus J_g, \\
\lambda^G_i &= 0, i \in \{1, \ldots , m\} \setminus J_G, \\
\lambda^H_i &= 0, i \in \{1, \ldots , m\} \setminus J_H, \\
\lambda^G_i &= \lambda^H_i = 0, i \in J_G \cap J_H.
\end{align*}
\]

Similarly as in [14, Theorem 4.3], we have the following result.

**Theorem 4.3** Assume that \( z^* \) is M-stationary in direction \( d \in \mathcal{C}_F(z^*) \) for MPSC (2) and assume that there exists some MPSC working set in direction \( d \). Then, \( z^* \) is strongly M-stationary in direction \( d \).

**Theorem 4.4** Let \( z^* \) be feasible for MPSC (2) and assume that MPSC-LICQ(\( d \)) is fulfilled at \( z^* \). Then, \( z^* \) is strongly M-stationary in direction \( d \) if and only if it is S-stationary in direction \( d \).

**Proof** The statement follows immediately from the fact that under MPSC-LICQ(\( d \)) there exists exactly one MPSC working set and this set fulfills \( J_g = \mathcal{I}_g^*(d), J_G = \mathcal{I}_G^*(d) \cup \mathcal{I}_{GH}^*(d), J_H = \mathcal{I}_H^*(d) \cup \mathcal{I}_{GH}^*(d) \).

In [31, Example 5.2], it was shown that the optimal solution of the following problem is M-stationary but not S-stationary. But we can show that MPSC-LICQ(\( d \)) holds at \( z^* \) and \( z^* \) is S-stationary in any nonzero critical direction.

**Example 4.1** [31, Example 5.2] Consider the following optimization problem
\[
\begin{align*}
\min & \quad z_1 + z_2^2 \\
\text{s.t.} & \quad -z_1 + z_2 \leq 0, \quad z_1z_2 = 0.
\end{align*}
\]

Its unique global minimizer is given by \( z^* := (0, 0) \). The linearization cone and critical cone of this problem at \( z^* \) are given by
\[
\begin{align*}
\mathcal{L}_F^\text{lin}(z^*) &= \{d \in \mathbb{R}^2| -d_1 + d_2 \leq 0, d_1d_2 = 0\}, \\
\mathcal{C}_F(z^*) &= \{d \in \mathbb{R}^2| -d_1 + d_2 \leq 0, d_1d_2 = 0, d_1 \leq 0\} = \{d \in \mathbb{R}^2|d_1 = 0, d_2 \leq 0\}.
\end{align*}
\]

Define \( g(z) := -z_1 + z_2, G(z) := z_1, H(z) := z_2 \). Let \( 0 \neq d \in \mathcal{C}_F(z^*) \), then \( \mathcal{I}_g^*(d), \mathcal{I}_H^*(d), \mathcal{I}_{GH}^*(d) \) are all empty but the index set \( \mathcal{I}_G^*(d) = \{1\} \). Hence, MPSC-LICQ(\( d \)) holds at \( z^* \). It is easy to check that \( z^* \) is indeed S-stationary in any direction \( 0 \neq d \in \mathcal{C}_F(z^*) \).
The strong M-stationarity in direction $d$ builds a bridge between M-stationarity in direction $d$ and S-stationarity in direction $d$. We summarize the relations among the various stationarity concepts in Fig. 2.

5 Error Bound and Exact Penalty for MPSC

In this section, we show the error bound property under two types of constraint qualifications: one is based on the local decomposition approach, and the other is based on the directional quasi-normality.

First, we discuss the local decomposition approach. For fixed $(\beta_1, \beta_2) \in \mathcal{P}(I_G \cup \beta_1)$, define

\[
\text{NLP}(\beta_1, \beta_2) \min f(z) \\
\text{s.t. } g(z) \leq 0, h(z) = 0, G_i(z) = 0, i \in I_G \cup \beta_1, H_i(z) = 0, i \in I_H \cup \beta_2.
\]

Definition 5.1 Let $z^*$ be a feasible point of MPSC (2). We say that $z^*$ satisfies

- MPSC piecewise MFCQ/CRCQ/CPLD/RCRCQ/RCPLD/CRSC, if for each $(\beta_1, \beta_2) \in \mathcal{P}(I^*_G(z^*))$, MFCQ/CRCQ/CPLD/RCRCQ/RCPLD/CRSC holds for (NLP($\beta_1, \beta_2$)) at $z^*$.

We now compare the piecewise constraint qualifications just defined with MPSC-MFCQ/CRCQ/CPLD as defined in Sect. 2.2. It is easy to see that if MFCQ/CRCQ/CPLD holds for (TNLP) at $z^*$ then for any $(\beta_1, \beta_2) \in \mathcal{P}(I^*_G(z^*))$, MFCQ/CRCQ/CPLD holds for (NLP($\beta_1, \beta_2$)) at $z^*$. Hence, MPSC-MFCQ/-CRCQ/-CPLD implies MPSC piecewise MFCQ/CRCQ/CPLD.

MPSC piecewise MFCQ/CRCQ/CPLD does not imply MPSC-MFCQ/-CRCQ/-CPLD. For example, consider MPSC with constraint system $G(z) = -z_1, H(z) =$
\[ z_1 - z_1^2 z_2^2 \text{ at } z^* = (0, 0). \quad \nabla G(z) = (-1, 0)^T, \quad \nabla H(z) = (1 - 2z_1 z_2^2, -2z_1^2 z_2). \] For (TNLP), CPLD does not hold at \( z^* \), but for \( \text{NLP}(\beta_1, \beta_2) \), LICQ holds at \( z^* \), then MFCQ/CRCQ/CPLD holds at \( z^* \). This counter example shows that MPSC piecewise MFCQ/CRCQ/CPLD is strictly weaker than MPSC-MFCQ/-CRCQ/-CPLD.

Since piecewise constraint qualifications are required to hold for all pieces, they may be harder to verify than the non-piecewise version. However sometimes, these two concepts may be equivalent. For example, it was shown in [39] that MPSC piecewise CRSC which is the weakest one among all the piecewise constraint qualifications introduced will imply the error bound property. For this purpose, we first give the following definition for local error bound property of MPSC (2).

**Definition 5.2** We say that **MPSC local error bound** holds around \( z^* \in \mathcal{F} \) if there exists a neighborhood \( V(z^*) \) of \( z^* \) and \( \alpha > 0 \) such that

\[
\text{dist}_{\mathcal{F}}(z) \leq \alpha \left( \sum_{i=1}^{p} \max\{g_i(z), 0\} + \sum_{i=1}^{q} |h_i(z)| + \sum_{i=1}^{m} \min\{|G_i(z)|, |H_i(z)|\} \right) \quad \forall z \in V(z^*).
\]

**Theorem 5.1** If \( z^* \in \mathcal{F} \) verifies MPSC piecewise CRSC, then MPSC local error bound holds in a neighborhood of \( z^* \).

**Proof** Recall that the definition of MPSC piecewise CRSC means that for any \((\beta_1, \beta_2) \in \mathcal{P}(\mathcal{I}_{GH}^\ast)\), CRSC holds for nonlinear programs \( \text{NLP}(\beta_1, \beta_2) \) at \( z^* \). When \( i \in \mathcal{I}_{GH}^\ast \), \(|H_i(z^*)| > |G_i(z^*)| = 0\), there exists a neighborhood \( V_G(z^*) \) of \( z^* \) such that \(|H_i(z)| \geq |G_i(z)|\), then we have \( \min\{|G_i(z)|, |H_i(z)|\} = |G_i(z)|\), for \( i \in \mathcal{I}_{GH} \) and \( z \in V_G(z^*) \). Similarly, there exists a neighborhood \( V_H(z^*) \) of \( z^* \) such that \( \min\{|G_i(z)|, |H_i(z)|\} = |H_i(z)|\), for \( i \in \mathcal{I}_{GH}^\ast \) and \( z \in V_H(z^*) \). Thus, by [19, Corollary 4.1] we have that for \((\beta_1, \beta_2) \in \mathcal{P}(\mathcal{I}_{GH}^\ast)\), there exist a neighborhood \( V_{\beta_1, \beta_2}(z^*) \) and a constant \( \alpha_{\beta_1, \beta_2} \) such that

\[
\text{dist}_{\mathcal{F}}(z) \leq \alpha_{\beta_1, \beta_2} \left( \sum_{i=1}^{p} \max\{g_i(z), 0\} + \sum_{i=1}^{q} |h_i(z)| + \sum_{i \in \mathcal{I}_{GH} \cup \beta_1} |G_i(z)| + \sum_{i \in \mathcal{I}_{GH}^\ast \cup \beta_2} |H_i(z)| \right) \]

\[
= \alpha_{\beta_1, \beta_2} \left( \sum_{i=1}^{p} \max\{g_i(z), 0\} + \sum_{i=1}^{q} |h_i(z)| + \sum_{i \in \mathcal{I}_{GH}^\ast} \min\{|G_i(z)|, |H_i(z)|\} \right) \]

\[
+ \sum_{i \in \mathcal{I}_{GH}^\ast} \min\{|G_i(z)|, |H_i(z)|\} + \sum_{i \in \beta_1} |G_i(z)| + \sum_{i \in \beta_2} |H_i(z)| \right),
\]

for all \( z \in V_{\beta_1, \beta_2}(z^*) \). Taking \( \alpha := \max_{(\beta_1, \beta_2) \in \mathcal{P}(\mathcal{I}_{GH}^\ast)} \alpha_{\beta_1, \beta_2}, V(z^*) := \cap_{(\beta_1, \beta_2) \in \mathcal{P}(\mathcal{I}_{GH}^\ast)} V_{\beta_1, \beta_2}(z^*) \), we get for all \( z \in V(z^*) \)

\[
\text{dist}_{\mathcal{F}}(z) \leq \alpha \left( \sum_{i=1}^{p} \max\{g_i(z), 0\} + \sum_{i=1}^{q} |h_i(z)| + \sum_{i \in \mathcal{I}_{GH}^\ast} \min\{|G_i(z)|, |H_i(z)|\} \right)
\]
Finally, it holds for all \((\beta_1, \beta_2) \in \mathcal{P}(\mathcal{I}^*_{GH})\). Set
\[
\beta^*_1(z) := \{i \in \mathcal{I}^*_{GH} \mid |G_i(z)| = \min\{|G_i(z)|, |H_i(z)|\}, \quad \beta^*_2(z) := \mathcal{I}^*_{GH} \setminus \beta^*_1(z),
\]
then \((\beta^*_1(z), \beta^*_2(z)) \in \mathcal{P}(\mathcal{I}^*_{GH})\).

Then, we have
\[
\text{dist}_{\mathcal{F}}(z) \leq \alpha \left( \sum_{i=1}^{p} \max\{g_i(z), 0\} + \sum_{i=1}^{q} |h_i(z)| + \sum_{i \in \mathcal{I}^*_G} \min\{|G_i(z)|, |H_i(z)|\} 
+ \sum_{i \in \mathcal{I}^*_H} \min\{|G_i(z)|, |H_i(z)|\} 
+ \sum_{i \in \beta^*_1(z)} \min\{|G_i(z)|, |H_i(z)|\} \right) 
= \alpha \left( \sum_{i=1}^{p} \max\{g_i(z), 0\} + \sum_{i=1}^{q} |h_i(z)| + \sum_{i=1}^{m} \min\{|G_i(z)|, |H_i(z)|\} \right).
\]
This completes the proof. \(\square\)

Now, we discuss the second approach based on the directional quasi-normality. First, we need the following calculation.

**Lemma 5.1** Under the \(l_1\)-norm, the distance functions are given by the following expressions for \(a, b \in \mathbb{R}\):
\[
dist_{(-\infty, 0]}(a) = \max\{a, 0\}, \quad \text{dist}_{[0]}(a) = |a|,
\]
\[
dist_{\Omega_{SC}}((a, b)) = \min\{|a|, |b|\} = \begin{cases} 
a \text{ or } b & a = b \geq 0, 
b & |a| > b \geq 0, 
-b & |a| > -b \geq 0, 
a & |b| > a \geq 0, 
-a & |b| > -a \geq 0, 
-a \text{ or } -b & a = b \leq 0. \end{cases}
\]

**Theorem 5.2** Let \(z^* \in \mathcal{F}\) such that MPSC directional quasi-normality holds. Then, MPSC local error bound holds in a neighborhood of \(z^*\).

**Proof** If MPSC directional quasi-normality holds at \(z^*\), then by [5, Corollary 4.1], the set-valued map \(F(z) := P(z) - \Lambda\) is metrically subregular at \((z^*, 0)\). By the definition of metric subregularity, there exist \(\alpha \geq 0\) and a neighborhood \(N(z^*)\) of \(z^*\) such that
\[
\text{dist}_{\mathcal{F}^{-1}(0)}(z) \leq \alpha \text{dist}_\Lambda(P(z)) \quad \forall z \in N(z^*).
\]
Recall the distance functions in Lemma 5.1, we complete the proof. \[\Box\]

By Clarke’s exact penalty principle [9, Proposition 2.4.3], we obtain the following exact penalty result immediately.

**Theorem 5.3** Let \(z^*\) be a local optimal solution of MPSC (2). If either MPSC directional quasi-normality or MPSC piecewise CRSC holds at \(z^*\), then \(z^*\) is a local optimal solution of the penalized problem:

\[
\min f(z) + L_f \alpha \left[ \sum_{i=1}^{p} \max \{0, g_i(z)\} + \sum_{i=1}^{q} |h_i(z)| + \sum_{i=1}^{m} \min \{|G_i(z)|, |H_i(z)|\} \right],
\]

where \(\alpha\) is the error bound constant and \(L_f\) is the Lipschitz constant of \(f\) around \(z^*\).

### 6 Conclusions

In Fig. 3, we give a diagram displaying the relations of various constraint qualifications, stationary conditions and error bounds. Note that in the diagram, the arrows pointing to stationary points only hold for local optimal solutions. MPSC Linear CQ means all defining constraint functions \(g, h, G, H\) are all affine. The relation between MPSC piecewise RCPLD and MPSC-RCPLD can be checked easily by using definitions. The proof of relation between MPSC-RCPLD and AM-regularity is similar to [4, Theorem 4.8]. To obtain all other relationships, we use definitions and the results presented here together with the results from [5,13,26,31]. From the diagram, we can see that directional conditions in a nonzero critical direction \(d\) are weaker than the corresponding nondirectional ones.
