Abstract
The coronavirus disease-2019 (COVID-19) has quickly spread all over the world and has contributed to psychological consequences including fear of the virus. Depending upon the severity of their problems, individuals often search the internet via their mobile devices to understand whether the symptoms they perceive are symptoms of the disease. This condition has been termed ‘cyberchondria’. In this context, the aim of this study is examine the mediating and moderating role of cyberchondria severity in the association between smartphone addiction and the fear of COVID-19. The sample comprised 520 participants (335 females [64.4%], 185 males [35.6%] aged 17 to 65 years [Mean = 28.61 years, SD = 10.60]). A survey included the Cyberchondria Severity Scale Short-Form, The Smartphone Addiction Scale-Short Version, and The Fear of COVID-19 Scale. Structural equation modeling and SPSS Process Macro moderator variable analysis were used to test the research model. The study found a positive association between smartphone addiction, fear of COVID-19, and cyberchondria severity. Cyberchondria severity had both moderating and mediating role in the association between smartphone addiction and the fear of COVID-19. In conclusion, it has been determined that during the COVID-19 pandemic, cyberchondria severity has negative effects on individuals’ fear of COVID-19.

Keywords Cyberchondria severity · Fear of COVID-19 · Health concern · Pandemic · Smartphone addiction

Introduction
The coronavirus disease-2019 (COVID-19) which first appeared in China in December 2019, quickly spread all over the world. The World Health Organization declared the disease as a pandemic in March 2020 (WHO, 2020a). Due to the high transmission rate of the COVID-19 virus, the number of cases and deaths seen around the world has increased rapidly. At the time of writing, the number of COVID-19 cases was over 44 million and over 1.7 million deaths (WHO, 2020b). It is accepted that the rapidly spreading negative effects of the COVID-19 virus is a potential death threat among individuals and societies (Pakpour & Griffiths, 2020). Therefore, countries have implemented various measures including national lockdowns, curfews, wearing masks in public places, spatial distance practices, and travel restrictions since the very beginning of the pandemic process to reduce the negative effects of the virus (Liu et al., 2020; Xiang et al., 2020). As the destructive impact of the pandemic on the world has increased, so too has the number and frequency of these measures increased (Cao et al., 2020; Zhang & Ma, 2020). However, these increased measures have caused individuals to radically change their daily routines and has resulted in increased fear and panic among many individuals (Huang & Zhao, 2020; Rajkumar, 2020; Qiu et al., 2020). In addition, the intense implementation of the social isolation measure to reduce the transmission power of the virus during the pandemic process and the constant telling of individuals what they should do to protect themselves from the virus caused an increase in the fear of COVID-19 (Lau et al., 2010). Because the measures that are repeated and excessively emphasized during pandemic
periods have a positive function such as raising awareness of the dangers of COVID-19 among individuals, it can also contribute to individuals worrying more about their health (Stacevic & Berle, 2013). For this reason, individuals who have been exposed to intense warnings about the virus during the COVID-19 pandemic experience health concerns, constantly check for symptoms of the virus, and start doing their own online research to assure themselves (Cao et al., 2020; Gao et al., 2020). Consequently, individuals have started to feel fear and anxiety about the possibility of COVID-19 infecting them and/or their families (Asmundson & Taylor, 2020; Pakpour & Griffiths, 2020).

Most individuals who stayed and/or worked from home during the pandemic period have accessed developments related to COVID-19 via the internet (e.g., news on social media) (Jungmann & Witthöft, 2020). Because in this period, individuals had to spend most of their daily time at home due to pandemic measures and started to access all developments related to the pandemic via the internet (García-Priego et al., 2020). This situation caused the production and rapid spread of many false information about the COVID-19 virus in cyber environments during the pandemic period (Brown et al., 2019; Garfin et al., 2020; Laato et al., 2020a, b). However, people have started to share this information about the pandemic without evaluating whether it is correct or wrong (Hashemi et al., 2020). Because, researches state that individuals are not very careful about whether the sharing about the virus is correct during pandemic periods and they carry out an intense sharing traffic about the epidemic (Bao et al., 2020; Garfin et al., 2020). In addition, those with high levels of anxiety (BraiIovskaia & Margraf, 2021; Elhai et al., 2020a, b), low tolerance for uncertainty (He et al., 2021), fear of missing out on developments related to the disease (Casale & Flett, 2020; Gioia et al., 2021) and individuals who feel high levels of loneliness (Gioia et al., 2021) are doing more research on the COVID-19 virus online and sharing more information online. The posts made to protect themselves, to follow the developments related to the pandemic, and to control health concerns started to get out of control after a while, and these posts in cyber environments started to cause individuals to increase their fear of COVID-19 (Jugmann et al., 2020). This sharing of misinformation in online environments can also cause an increase in individuals' fear of COVID-19 (Jugmann et al., 2020). This situation has led to the formation of a new problem area related to the COVID-19 pandemic, and has shown the risk of emotional transmission due to sharing in online environments beyond the risk of physical transmission of the virus (Gao et al., 2020; Roy et al., 2020). The World Health Organization stated that the misinformation that individuals access online concerning COVID-19 can cause psychological and physical pathological consequences (WHO, ). In various parts of the world, deaths have been reported of individuals who have followed the online advice and misinformation about COVID-19 treatment (Milliyet Newspaper, 2020; Sabah Newspaper, 2020; Euronews-Internet News, 2020). Such stories demonstrate how serious the situation can be for some individuals. Consequently, the World Health Organization has recommended that countries address the information needs of all individuals concerning COVID-19 and that accurate and reliable information is provided in all media channels in order to prevent other problems (WHO, 2020b). In fact, there have been attempts to open a special area on the WHO website to refute false information concerning COVID-19 (WHO, 2020c).

When research concerning the COVID-19 pandemic and the statements made by WHO are evaluated together, it demonstrates that it is important to not only protect individuals from the risk of physical transmission of the disease, but also to support their mental health (Ahorsu et al., 2020; Wang et al., 2020). Previous studies have also shown that individuals can experience intense negative emotions such as stress, fear, and anxiety during pandemic periods (e.g., H1N1-2010, SARS-2009) (Lau et al., 2010; Peng et al., 2010; Saadatian-Elahi et al., 2010). Consequently, considering the transmission rate of the COVID-19 virus, the potential risk of death, and the rate of spread throughout the world, it is inevitable that some individuals will experience fear and anxiety about this issue (Hashemi et al., 2020). In an environment that rapidly affects the whole world and thousands of new cases and deaths every day, the mental health concerns of individuals continue to increase gradually (Ahorsu et al., 2020; Fitzpatrick et al., 2020).

Many studies have reported that anxiety and stress caused by the fear of COVID-19 negatively affects the mental health of individuals (e.g., Ahorsu et al., 2020; Bakioğlu et al., 2020; Lai et al., 2020; Xiao et al., 2020). In addition to these negative effects of the pandemic, another negative effect is the increased use of technology. This situation has made individuals vulnerable to the negative effects of the internet and online tools. Due to the measures implemented in the COVID-19 pandemic, people who stayed at home started to follow the developments related to the pandemic through online communication tools, and this caused individuals to use technological elements (internet, social media, smart phone) more (Kiraly et al., 2020; MattiuZZi & Lippi, 2020). For this reason, it is said that the increase in the use of internet and information technologies during the pandemic period may also affect the fears of individuals against COVID-19 (Elhai et al., 2020a, b; Hashemi et al., 2020). With this increasing use of technology, individuals are exposed to more news of COVID-19, as well as they may encounter many false information about the epidemic (Bao et al., 2020). In addition, it is reported that the intense use of technological tools (internet, social media, smart phone)
by people causes false information about COVID-19 to spread rapidly in the society and this situation triggers health anxiety in people (Rovetta & Bhagavathula, 2020; Xiao et al., 2020). Individuals affected by the information and news about the pandemic shared online increasingly feel anxiety, fear and anxiety (Li et al., 2020). Prior to the pandemic, studies reported that excessive use of smartphones, internet and social media were associated with anxiety, stress, and depression among a minority of individuals (Bragazzi & Puente, 2014; Çakır & Oğuz, 2017; Franchina et al., 2018; Soni et al., 2017). Given the apparent increase in technology use of individuals during the COVID-19 pandemic, this may also have a negative effect on some individuals’ fear of COVID-19 (Gao et al., 2020; Kiraly et al., 2020).

Due to the excessive use of smartphones by some individuals, research into smartphone addiction has emerged (Griffiths & Szabo, 2014; Kwon et al., 2013). With smartphones, individuals can engage in many activities such as accessing the internet, playing games, and accessing social media on a single device, wherever and whenever they want (Geser, 2006; Griffiths, 2013). The fact that individuals can engage in many different activities on a single device has led to a large increase in smartphone use (King et al., 2013; Yilmaz et al., 2015). During the COVID-19 pandemic, the main source of information for individuals at home has been online websites (García-Priego et al., 2020). In this period, individuals had to use the internet and technological devices more in order to reach news about COVID-19 (Gao et al., 2020; Kiraly et al., 2020).

The increased use of technology and online communication tools in the COVID-19 pandemic has increased the risks of individuals becoming addicted to smartphones (Duran, 2020; Elhai et al., 2020a, b; Gür, 2020). Because individuals have started to use the internet and social media more actively, both to communicate with other people and to follow the developments related to the epidemic, due to the restricted social life during the pandemic period and the measures taken due to the pandemic (Xiao et al., 2020). Since smartphones offer individuals the opportunity to use all online communication tools through a single device (Kwon et al., 2013), the rate of smartphone use by individuals has increased gradually during the pandemic period (Elhai et al., 2020a, b; Gür, 2020). It is also stated that the use of smartphones as a means of getting emotional support and coping during the social isolation periods in the COVID-19 pandemic may cause the time spent by individuals with their smartphones to prolong (Sha et al., 2019). This result shows that smartphones are used not only as a means of obtaining information during the pandemic period, but also as a means of socialization and support seeking. Due to all these reasons explained above, it can be said that the risk of smartphone addiction is increasing, as the time spent by individuals with smartphones is gradually increasing in the COVID-19 pandemic.

Studies during the pandemic have also shown that individuals are not selective about the accuracy of sharing and information about the disease and that they constantly share information concerning COVID-19 (Bao et al., 2020; Garfin et al., 2020). As the time spent on smartphones increases, individuals are more likely to encounter false information about the pandemic and fears may rise (Lei et al., 2020; Li et al., 2020). Furthermore, intensive use of smartphones by individuals causes the rapid spread of misinformation about COVID-19 in the society and this situation causes serious increases in individuals’ health concerns (Mattuzzi & Lippi, 2020; WHO, 2019; Wang et al., 2020). COVID-19 fears are likely to rise due to a vicious circle in which individuals turn to their smartphones, internet, and social media in order to relieve their concerns and reduce the stress they experience, but can become a negative coping method because the information they find increases their stress, anxiety and/or fear (Qiu et al., 2020; Xiao et al., 2020).

Individuals’ reactions to pandemics are known to vary (White & Horvitz, 2009). However, studies have reported that individuals experience more anxiety and fear during pandemic periods and therefore develop behaviors that will make them feel safe (Gaygısız et al., 2012; Main et al., 2011). Depending upon the severity of the anxiety, individuals often search the internet to understand whether the symptoms they perceive are symptoms of the disease (Norr et al., 2015; White & Horvitz, 2009). This condition, which has been termed ‘cyberchondria’, is defined as the behavior of individuals who experience excessive fear of being sick to search for the symptoms they perceive online (Starcevic & Berle, 2013). In studies on cyberchondria, the main reason for this behavior is health anxiety (Norr et al., 2015; Starcevic & Berle, 2013).

It has been found that social isolation during the COVID-19 period, the increasing use of the internet and technological devices, and the easy access to all kinds of information about the virus online may cause the increase of cyberchondria behavior during the pandemic period (Rovetta & Bhagavathula, 2020). Because in some studies in the literature, it has been reported that there is a positive correlation between problematic internet use and cyberchondria (Starcevic, 2017; Starcevic & Berle, 2013; Vismara et al., 2020; White & Horvitz, 2009). This situation has caused individuals to encounter more sharing about the pandemic online. In addition, as the effect of the pandemic expanded, the health concerns of individuals began to rise and the frequency of observation of cyberchondria behaviors began to increase as the searches they made on the internet about COVID-19 increased (Husnayain et al., 2020). In order to alleviate this concern, people searching the internet have faced many wrong information about the pandemic,
and even some wrong individuals have been harmed due to incorrect information (Kim & Dennis, 2019). As a result, with the increase in online tool usage rates during the pandemic period, the rates of individuals exhibiting cyberchondria behaviors have also increased (Hashemi et al., 2020; Laato et al., 2020a, b).

It is stated that the risk factors of individuals becoming technology addicted increase in the COVID-19 pandemic (Király et al., 2020). In support of this opinion, some studies in the literature state that the time individuals spend with the internet, social media and smartphones during the COVID-19 pandemic has increased (Gao et al., 2020; Garcia-Priego et al., 2020; Hashesmi et al., 2020; Kayiş et al., 2021). In addition, due to the social distance and social isolation measures implemented during the pandemic period, people had to spend most of their time at home (Oosterhoff et al., 2020). During this time, they stayed at home, they started to use online tools more intensively to follow the developments related to the pandemic and to communicate with their relatives, which led to an increase in the time individuals spend on the internet, social media and smart phone (Alheneidi et al., 2021; Garcia-Priego et al., 2020; Islam et al., 2020a, b; King et al., 2020). On the other hand, individuals who feel a high level of health anxiety have implemented a stricter social isolation measure and have started to meet all their communication and social needs through online communication tools (Elhai et al., 2021). With the increase in time spent with online communication tools and technological devices, individuals have encountered more news about the pandemic shared online, and as a result, they have begun to feel more health anxiety (Kayiş et al., 2021; Schimmenti et al., 2020; Vismara et al., 2020). Individuals with increased health anxiety and intense use of online communication tools have tended to do more online research about the disease (Cline and Haynes, 2001; Doherty-Torstrick et al., 2016; Starcevic, 2017). These findings in the literature form the basis of a possible relationship between the smartphone, cyberchondria and fear of COVID-19 investigated in the current research. Because it can be thought that individuals who use their smartphones intensively in the COVID-19 pandemic will be exposed to a lot of information about the virus, so their health concerns will increase and they will do research on the virus over the internet to control these concerns. On the other hand, the Person-Affect-Cognition-Execution (I-PACE) model developed by Brand et al. (2016) forms a basis for the relations between the variables in the current research and the established structural equation model. According to the I-PACE model, it is stated that excessive internet and smartphone use of individuals causes anxiety and stress in them, and individuals tend to use the internet again to cope with these anxiety and stress (Brand et al., 2016). In the COVID-19 pandemic, it seems very possible for individuals to enter a vicious circle expressed in the I-PACE model, and this situation to have a negative effect on individuals' fear of COVID-19. As a result, when all the above research findings are evaluated together, it is thought that smartphone addiction may increase the cyberchondria behaviors and the fear of COVID-19, but the cyberchondria behaviors performed over the smartphone may cause individuals to increase their fear of COVID-19 more.

The present study

In a report published by We Are Social (2020a), it was claimed that among the world’s 7.5 billion individuals, 60% are internet users, 67% use smartphones, and 49% are active social media users. In the same report, it was reported that the means used by individuals for internet access was smartphones with a rate of 92%. This means that approximately 4.5 billion of the world population is internet users and approximately 3.8 billion are social media users. In another report, We Are Social (2020b) claimed that in Turkey which has a population of 83.88 million (where the present study was carried out), 92% use smartphones, 64% use social media and 74% are internet users. These results suggest Turkey's internet and technology utilization rate is well above the world average. It is thought that this increase in the use of technology during the pandemic period may increase the likelihood of individuals encountering misinformation concerning COVID-19, and that this will be associated with increased levels of fear and anxiety. For all these reasons, the present study examined the mediating and moderating role of cyberchondria severity in the association between smartphone addiction and the fear of COVID-19. In the present study, the following hypotheses (Hs) were examined:

\[ H_1 \] Smartphone addiction will positively influence the fear of COVID-19.

\[ H_2 \] Smartphone addiction will positively influence the severity of cyberchondria.

\[ H_3 \] Cyberchondria severity will positively influence the fear of COVID-19.

\[ H_4 \] Cyberchondria severity will have a mediating role in the association between smartphone addiction and the fear of COVID-19.

\[ H_5 \] Cyberchondria severity will have a moderating role in the association between smartphone addiction and the fear of COVID-19.
Method

Participants and procedure

The participants comprised 520 individuals [335 females (64.4%), 185 males (35.6%)]. Participants’ ages ranged from 17 to 65 years (mean = 28.61; SD = 10.60). A total of 520 of the participants stated that they had low socioeconomic level (10%), 421 medium socioeconomic level (81%), and 47 high socioeconomic level (9%). Participants were recruited through public social media groups. The data were collected online from volunteer participants (via Google Forms in October and November 2020). The scales took approximately 10 min to respond.

Measures

The Cyberchondria Severity Scale Short-Form (CSS-12)

McElroy and Shevlin (2014) originally developed the 33-item Cyberchondria Severity Scale. A shorter 12-item version (CSS-12) was then developed by McElroy et al. (2019). The CSS-12 assesses the severity of individuals searching for disease symptoms online. The scale comprises four sub-dimensions (i.e., Excessiveness, Distress, Reassurance, Compulsion). Items are scored using five-point scale ranging from 1 (Never) to 5 (Always). Total scores that can be obtained from the scale is ranging from 0 to 60. The higher total score means a high level of cyberchondria severity.

The original CSS was adapted into Turkish by Selvi et al. (2018). However, the Turkish validity and reliability study of the CSS-12 has not been conducted. Therefore, the present study tested the validity (using confirmatory factor analysis [CFA]) and reliability (Cronbach Alpha internal consistency coefficients) of the CSS-12. CFA examining the four-factor construct validity of the scale was carried out. The goodness of fit values were: χ² = 219.01, p < 0.001, df = 48; CFI = 0.943; TLI = 0.922; RMSEA = 0.08 (90% CI = 0.07-0.09). Item-factor loads for the four-factor structure varied between 0.48 and 0.90. Calculated corrected item-total correlations for the scale vary between 0.58 and 0.85. The Cronbach Alpha internal consistency coefficient for the total score in the present study was very good (0.89) and good to very good for the sub-dimensions: Excessiveness (0.83), Distress (0.79), Reassurance (0.70), and Compulsion (0.80).

The Smartphone Addiction Scale-Short Version (SAS-SV)

The scale was developed by Kwon et al. (2013) and assesses the risk of smartphone addiction (Turkish version: Noyan et al., 2015). It comprises 10 items and is uni-dimensional. Items are responded to on a six-point scale from 1 (I strongly disagree) to 6 (I strongly agree) with total scores ranging from 10 to 60. The higher the score, the higher the risk of smartphone addiction. The Cronbach Alpha coefficient in the present study was excellent (0.92).

The Fear of COVID-19 Scale (FCV-19S)

The scale was developed by Ahorsu et al. (2020) and assesses fear of COVID-19. It was validated by Satici et al. (2020). It comprises seven items and is uni-dimensional. Items are responded to on a five-point scale ranging from 1 (Strongly disagree) to 5 (Strongly agree) with total scores ranging from 7 to 35. The higher the score the higher the level of fear of COVID-19. The Cronbach Alpha coefficient was found to be sufficient in this study (0.86).

Data analysis

Before the analysis, the distribution of the data was examined. When the kurtosis and skewness values were examined, the data showed a normal distribution. Pearson correlation, the independent samples t-test and one-way ANOVA analysis were used. Structural equation modeling and SPSS Process Macro moderator variable analysis were used to test the research model (Fig. 1).

In the examination of the goodness of fit values of the structural equation model, χ²/df < 5; GFI, TLI, CFI, > 0.90; RMSEA < 0.10 values were taken as basis for good fits (Hu & Bentler, 1999). Bootstrapping tests were used to examine whether cyberchondria severity mediated the relationship between the smartphone addiction and the fear of COVID-19 (Hayes, 2018). To test the indirect effect of smartphone addiction on fear of COVID-19, bootstrapping confidence interval was calculated (10,000 resamples). IBM SPSS Statistics 26 and AMOS Graphics 24 were used for the analyses.

Results

Descriptive statistics

Information on the descriptive statistics of the participants is shown in Table 1. According to the results of the independent samples t-test, females had a higher fear of COVID-19 than males \((t(518) = 3.67, p < 0.001)\). However, there were no gender differences for smartphone addiction and cyberchondria severity. According to a one-way ANOVA, fear of COVID-19, smartphone addiction and cyberchondria severity did not differ according to the socioeconomic levels of the participants. As expected, in relation to the duration of daily smartphone use, the smartphone addiction levels of the participants differed significantly in all groups \((F(517,2) = 63.69, p < 0.001)\). However, fear of COVID-19 and cyberchondria severity did not differ according to duration of daily smartphone use. In relation to duration of daily social media use time, levels of smartphone addiction \((F(517,2) = 1.04, p < 0.001)\) and cyberchondria severity \((F(517,2) = 5.91, p < 0.001)\) significantly differed. There was a significant difference in all three groups in relation to duration of daily social media use time (0–1 h daily use, 1–3 h daily use, above 3 h daily use) in smartphone addiction. However, it was found that individuals who spent more than three hours daily on social media had higher levels of cyberchondria than those who spent less daily time on social media. Finally, it was found that fear of COVID-19 did not differ according to daily time spent on social media use.

Correlation analysis

Correlations between variables are shown in Table 2. As shown in Table 2, the variables examined in the study had significant positive relationships. Fear of COVID-19 had a significant relationship with cyberchondria and smartphone addiction. In addition, there was a positive significant relationship between cyberchondria and smartphone addiction.

### Table 1 Descriptive statistics

| Variables                  | f    | %     | M₁    | SD₁   | M₂    | SD₂   | M₃    | SD₃   |
|----------------------------|------|-------|-------|-------|-------|-------|-------|-------|
| Gender                     |      |       |       |       |       |       |       |       |
| Male                       | 335  | 64.4% | 15.92 | 5.95  | 31.49 | 9.70  | 28.44 | 12.36 |
| Female                     | 185  | 35.6% | 13.99 | 5.59  | 31.41 | 9.73  | 26.38 | 11.63 |
| Socioeconomic status       |      |       |       |       |       |       |       |       |
| Low                        | 52   | 10%   | 16.77 | 5.53  | 33.94 | 9.67  | 28.79 | 13.22 |
| Middle                     | 421  | 81%   | 15.07 | 5.69  | 31.33 | 9.62  | 27.45 | 11.90 |
| High                       | 47   | 9%    | 15.26 | 7.70  | 29.87 | 10.10 | 28.83 | 13.08 |
| Daily smartphone use       |      |       |       |       |       |       |       |       |
| 0–1 h                      | 44   | 8.25% | 14.57 | 6.37  | 30.16 | 10.08 | 17.25 | 9.37  |
| 1–3 h                      | 196  | 37.7% | 14.89 | 5.43  | 30.83 | 9.15  | 23.24 | 9.31  |
| Above 3 h                  | 280  | 53.8% | 15.62 | 6.12  | 32.11 | 9.99  | 32.48 | 12.07 |
| Daily social media use     |      |       |       |       |       |       |       |       |
| 0–1 h                      | 141  | 27.1% | 14.65 | 5.53  | 29.75 | 10.11 | 20.10 | 9.56  |
| 1–3 h                      | 220  | 42.3% | 15.51 | 5.78  | 31.10 | 9.50  | 26.78 | 10.59 |
| Above 3 h                  | 159  | 30.6% | 15.44 | 6.35  | 33.48 | 9.29  | 35.74 | 11.38 |

M₁,₂,₃: Mean, SD₁,₂,₃: Standard Deviation
M₁ and SD₁: Fear of COVID-19, M₂ and SD₂: Cyberchondria Severity, M₃ and SD₃: Smartphone Addiction

### Table 2 Inter-correlations of the variables and descriptive statistics

| Variables                | 1    | 2    | 3    | Mean | SD  | Skewness | Kurtosis |

Mediating role of cyberchondria in the association between smartphone addiction and fear of COVID-19

The mediating role of cyberchondria severity in the association between smartphone addiction and fear of COVID-19 was tested. The figure containing the findings of the research model is shown in Fig. 2. Analysis demonstrated that the goodness of fit values of the model were within acceptable limits \( \chi^2 = 580.534, \text{df} = 181, p < 0.001, \chi^2/\text{df} = 3.207; \text{GFI} = 0.90; \text{TLI} = 0.92; \text{CFI} = 0.94; \text{RMSEA} = 0.07 \) (90% CI = 0.06 —0.07). Looking at the direct effects in the model were examined, it was found that smartphone addiction predicted fear of COVID-19 \( (\beta = 0.19, p < 0.001) \) and cyberchondria severity \( (\beta = 0.41, p < 0.001) \). Similarly, cyberchondria severity predicted fear of COVID-19 positively \( (\beta = 0.30, p < 0.001) \). When the findings regarding the indirect effects in the model were examined, it was found that smartphone addiction predicted fear of COVID-19 via cyberchondria severity \( (\beta = 0.12, p < 0.001) \). Path coefficients for indirect and direct effects are shown in Table 3.

As can be seen in Table 3, the path coefficient of all direct and indirect effects in the model were significant.

Moderating role of cyberchondria severity in the association between smartphone addiction and fear of COVID-19

Regression analysis was performed using Process Macro developed by Hayes (2018) in order to test the moderating role of cyberchondria severity in the effect of individuals’ smartphone addiction on their fear of COVID-19. The findings of the analysis are shown in Table 4. As shown in Table 4, all variables included in the analysis explained approximately 18% of fear of COVID-19 \( (F = 32.32, R^2 = 0.18, p < 0.001) \). Smartphone addiction \( (\beta = 0.11, p < 0.001) \) and cyberchondria severity \( (\beta = 0.16, p < 0.001) \) had positive and significant effects on fear of COVID-19. The moderating role of cyberchondria severity was significant in the relationship between smartphone addiction and fear of COVID-19 \( (\beta = 0.01, p < 0.01) \). It was also found that...
the increase in $R^2$ was significant by adding the interaction between smartphone addiction and cyberchondria severity (SA x CS) to the model ($F = 6.72$, $R^2$ change $= 0.012$, $p < 0.01$). The effects of smartphone addiction on fear of COVID-19 for different levels of cyberchondria severity are given in Table 5.

The analysis indicated that the effect of smartphone addiction on fear of COVID-19 for middle and high levels of cyberchondria severity was significant. However, it appears that this effect was not significant for low levels of cyberchondria severity. The slope graphs regarding the effects of the moderator variable are presented in Fig. 3. This shows that the effect of smartphone addiction on fear of COVID-19 increases in the middle and high levels of cyberchondria severity. In the case of high cyberchondria severity, this relationship is even stronger. Therefore, if cyberchondria severity is high, the effect of smartphone addiction on fear of COVID-19 is greater. This finding indicates that cyberchondria severity is a moderator in the relationship between smartphone addiction and fear of COVID-19.

Discussion

According to the first finding of the study, there is a positive association between smartphone addiction and the fear of COVID-19. In other words, it can be said that there is a linear relationship between smartphone addiction and the fear of COVID-19. These results show that the $H_1$ was supported. This result can be interpreted as individuals are exposed to a lot of information about the COVID-19 virus because they use their smartphones intensively during the pandemic period, and therefore their fear of COVID-19 has increased. There are studies reporting similar results in the literature. For example, Boursier et al. (2020) in their research concluded that the use of social media by individuals increased during the COVID-19 period, and this use positively predicted the fear of COVID-19 in a meaningful way. Elhai et al. (2020a) examined the relationship between problematic smartphone use and COVID-19 anxiety and found that there was a positive relationship between COVID-19 anxiety and smartphone addiction, and that smartphone addiction had a mediating effect between COVID-19 anxiety and general anxiety. Similarly, in another study, they concluded that there is a positive relationship between fear of COVID-19 and smartphone addiction (Kayiş et al., 2021). Servidio et al. (2021), it was revealed that there is a positive relationship between internet addiction and fear of COVID-19. On the other hand, in some studies, it is reported that individuals use technological devices more in the COVID-19 pandemic and this has a negative effect on their fear of COVID-19 (Hashemi et al., 2020; Kiraly et al., 2020; Yang et al., 2020).

In addition, it is stated that many false information about the COVID-19 pandemic is shared in the cyber environment and the fear of COVID-19 of individuals who are exposed to them increases (Brown et al., 2019; Garfin et al., 2020). It has even been claimed that during the pandemic period, sharing misinformation concerning COVID-19 increases the risk of emotional transmission among individuals and therefore individuals start to feel anxiety and fear about the COVID-19 (Gao et al., 2020; Roy et al., 2020; WHO, 2020c).

However, with social isolation, many individuals follow all developments related to the COVID-19 pandemic via their smartphones, and it has been claimed that COVID-19 fears may rise because this causes individuals to view many inaccurate shares and news stories (Hashemi et al., 2020). In addition, it has been claimed that during the COVID-19 pandemic, there has been a large increase in internet and social media use rates among individuals (Gao et al., 2020; Jungmann & Witthöft, 2020). In some studies, it has been reported that individuals with internet and social media addiction have higher fear of COVID-19 (Ahmad & Murad, 2020; Garcia-Priego et al., 2020; Islam et al., 2020a, b; Yu

![Fig. 3 The effects of smartphone addiction on fear of COVID-19 for different levels of cyberchondria severity](image-url)
These studies findings concur with the present study’s findings. However, the present findings are similar to the results of the studies conducted before the pandemic on smartphone addiction. Such studies have shown that smartphone addiction is associated with stress, anxiety, fear, and depression in individuals (Bragazzi & Puente, 2014; Çakır & Öğuz, 2017; Elhai et al., 2017, 2020b; Franchina et al., 2018; Soni et al., 2017). Taken together, the findings suggest that technological addictions have had negative effects on individuals’ fear of COVID-19 during the pandemic period. In addition, since the intensive use of smartphones increases the possibility of encountering misinformation about the COVID-19 virus, this provides a possible reason for why individuals have increased fear of COVID-19.

The second finding of the study showed that there was a significant positive relationship between smartphone addiction and cyberchondria severity. This suggests that individuals with smartphone addiction during the pandemic period exhibited higher cyberchondria behaviors. This finding supported H2. There are previous studies that have reported similar results to this finding. Abdelsattar et al. (2021) in their research on a sample group of Arab individuals, concluded that there is a positive relationship between the severity of cybercorderia and fear of COVID-19. In some studies, it has been concluded that addictions to smartphones, the internet and/or social media is associated with cyberchondria severity (Fergus & Spada, 2017; Ivanova, 2013; Ivanova & Karaboeva, 2014; Khazaal et al. 2020). Other studies have reported that individuals who experience intense anxiety and fear during pandemics engage in behaviors that make them safe (Gaygisiz et al., 2012; Main et al., 2011). Due to the measures implemented in the COVID-19 pandemic which can result in social isolation, individuals have come to follow the developments related to COVID-19 mostly on the internet via their smartphones in order to cope with their anxiety and fear and to feel safe (Duran, 2020; Elhai et al., 2020a; Gür, 2020). This may lead to an increase in technological addiction rates among individuals during the pandemic period (Elhai et al., 2020a; Gao et al., 2020). Cyberchondria severity may increase among individuals who seek out all kinds of information concerning COVID-19 during the pandemic period (Rovetta & Bhagavathula, 2020; Sha et al., 2019). Similarly, in another study, it was concluded that individuals who were addicted to smartphones during the COVID-19 period felt more health anxiety (Elhai et al., 2021). However, with the increase of the threatening effect of the pandemic, the fact that individuals seek out more information concerning COVID-19 on the internet is a factor that may cause an increase in cyberchondria severity (Husnayain et al., 2020). In addition, in some studies have reported that the COVID-19 pandemic has contributed to an increase in the health concerns among individuals, and as a result of this, individuals tend to seek out more information about the virus on the internet which triggers cyberchondria severity (Hashemi et al., 2020; Jungmann & Witthöft, 2020). The finding concerning the relationship between smartphone and cyberchondria severity is also consistent with the I-PACE (Interaction of Person-Affect-Cognition-Execution Model) model proposed (Brand et al., 2016). In this model, it states that individuals tend to use the internet and smartphones excessively to manage mood states such as anxiety and fears. Similarly, another study found that cyberchondria severity was associated with technological addictions (Vismara et al., 2020).

The third main finding of the study found a positive relationship between cyberchondria severity and the fear of Covid-19. This result indicates that individuals with high levels of cyberchondria behavior during the pandemic period also have higher fear of COVID-19. H3 was therefore supported. This has been found in previous studies. Farooq et al. (2020) concluded that individuals who conducted a lot of research concerning COVID-19 online had high concerns about the virus. In another study, it was observed that the cyberchondria behaviors exhibited in the COVID-19 pandemic increased their fear of COVID-19 (Jungman and Witt, 2020). However, when the literature is examined, it is found that the most important determinant of cyberchondria severity is health anxiety (Norr et al. 2015; Starcevic & Berle, 2013). In some studies, it has been revealed that individuals who have health concerns in the COVID-19 pandemic tend to do intensive research on the virus on the internet in order to secure themselves (Cao et al., 2020; Gao et al., 2020). In another study, it was concluded that there was a positive relationship between the severity of individuals’ cyberchondria and their fear of COVID-19 (Wu et al. 2021). Jokic-Begic et al. (2020) in a study they conducted on Croatian individuals, it was determined that as the level of cyberchondria of individuals increased, their fear of COVID-19 increased. Consequently, individuals have been found to increase their fear and anxiety levels regarding the disease because they view a lot of unconfirmed information about the virus (Laato et al., 2020a, b; Starcevic et al., 2021; Xie et al., 2011). It has been found that individuals with high cyberchondria severity seek out more information about diseases on the internet. These individuals are more likely to encounter false information about the virus because they make more internet searches concerning COVID-19.

The fourth finding of the study showed that cyberchondria severity had a partial mediating role in the association between smartphone addiction and the fear of COVID-19. This suggests that the fear of COVID-19 among individuals with smartphone addiction increases, but with high cyberchondria severity, the fear of COVID-19 among individuals increases even more. This finding supports H4. The fifth finding of the study showed that cyberchondria severity played a moderating role in the association between
smartphone addiction and the fear of COVID-19. According to this result, it appears that the relationship between smartphone addiction and the fear of COVID-19 in cases with moderate and high levels of cyberchondria severity is stronger than in cases with low cyberchondria severity. In other words, cyberchondria severity has a significant role in the association between smartphone addiction and the fear of COVID-19. This result supports H5. In the literature, there are studies that have reached similar results regarding the relationship between smartphone addiction, cyberchondria severity and fear of COVID-19 (Ahmad & Murad, 2020; Brown, et al., 2019; Elhai et al., 2020a; Farooq et al., 2020; Garfin et al., 2020; Husnayain et al., 2020; Jungmann & Withöfft, 2020). On the other hand, the literature shows that fear anxiety increases during pandemic periods, and that individuals’ information needs about many areas, especially health, increase and therefore tend to seek out more information online (Lau et al., 2010; Saadatian et al., 2010). In addition, it is stated that individuals exhibit more cyberchondriac behaviors during epidemic periods that affect the whole world such as a pandemic (Zheng et al., 2020). Because, with measures resulting in social isolation to prevent the spread of the virus, the time individuals spend on the internet and technological devices have increased. It can be stated that all these explanations support the present research findings.

**Limitations and future research**

The present study has some limitations. The study sample comprised individuals living in Turkey. Therefore, caution should be exercised when generalizing the present research results to individuals outside of the Turkish society. In future research, the present study could be repeated with groups of individuals from different countries and cultures to confirm the explanatory power of the model in other contexts. In addition, the present study was cross-sectional study and therefore is unable to provide unequivocal evidence for causality among the variables studied. Furthermore, all data were obtained by a self-report method. Therefore, longitudinal research utilizing other methodologies is needed to overcome these shortcomings. Finally, in the research model, only the relationship between smartphone addiction, cyberchondria severity and fear of COVID-19 was examined. In order to ensure the validity of the research results after the pandemic, the model can be examined with different types of fear that may affect variables such as cyberchondria and smartphone addiction.

**Conclusion**

The present study found that smartphone addiction was associated with an increase in COVID-19 fear among individuals during the pandemic. Similarly, during the pandemic period, it was found that individuals with higher smartphone addiction scores presumably access their smartphones to seek out health information. In addition, the study found that cyberchondria severity was associated with individuals’ fear of COVID-19. In other words, during the COVID-19 pandemic, it appears that individuals who searched online for health information and were exposed to a lot of inaccurate information increased their fear of COVID-19. However, it has been observed that cyberchondria severity has both a mediating and a moderating role in the relationship between smartphone addiction and the fear of COVID-19. This research revealed that in addition to the global fear of the COVID-19 pandemic, individuals who use excessive phones and have high cyberchondria behaviors have higher fear of COVID-19. The findings here indicate that it is important to control the cyberchondria behaviors with the use of smartphones so that individuals can combat the fear of COVID-19 more effectively.

These results obtained in the research also revealed the fact that it is very important for individuals to be made aware of the negative effects of internet and information technologies during epidemic periods. For this reason, it is important for governments to utilize their relevant departments (e.g., Ministries of Health) effectively in order to provide reliable information for individuals regarding COVID-19 during the pandemic period. Consequently, individuals’ anxieties and fears regarding COVID-19 would be supported in becoming more manageable. On the other hand, the findings of this research revealed that the intensive use of smartphones and research on the disease through smartphones may cause individuals to increase their fear of COVID-19 and to use their smartphones again. This situation indicates that individuals may enter a vicious circle that requires clinical intervention in terms of fear of COVID-19. For this reason, these results have revealed that it is important to examine the use of smartphones and the activities of individuals seeking psychological help due to fear of COVID-19, searching for information about diseases on their smartphones. In other words, we anticipate that, firstly, regulating the habits of using online communication tools and secondly, taking measures to reduce repetitive online disease researches can be two important strategies in order to control the COVID-19 fears of individuals during the pandemic period. In addition, this research has also shown that individuals’ cyberchondria behaviors play a role in increasing their fear of COVID-19. This result reveals that cyberchondria can cause a new medical crisis during epidemic periods such as pandemics, and therefore it is important to produce policies to raise awareness of individuals on how to use online tools in crisis periods such as epidemics.
