The effects of ball milling on the hydrogen sorption kinetics and microstructure of Zr$_{0.8}$Ti$_{0.2}$Co have been systematically studied. Kinetic measurements show that the hydrogenation rate and amount of Zr$_{0.8}$Ti$_{0.2}$Co decrease with increasing the ball milling time. However, the dehydrogenation rate accelerates as the ball milling time increases. Meanwhile, the disproportionation of Zr$_{0.8}$Ti$_{0.2}$Co speeds up after ball milling and the disproportionation kinetics is clearly inclined to be linear with time at 500°C. It is found from X-ray powder diffraction (XRD) results that the lattice parameter of Zr$_{0.8}$Ti$_{0.2}$Co gradually decreases from 3.164 Å to 3.153 Å when the ball milling time extends from 0 h to 8 h, which is mainly responsible for the hydrogen absorption/desorption behaviors. In addition, scanning electron microscope (SEM) images demonstrate that the morphology of Zr$_{0.8}$Ti$_{0.2}$Co has obviously changed after ball milling, which is closely related to the hydrogen absorption kinetics. Besides, high-resolution transmission electron microscopy (HRTEM) images show that a large number of disordered microstructures including amorphous regions and defects exist after ball milling, which also play an important role in hydrogen sorption performances. This work will provide some insights into the principles of how to further improve the hydrogen sorption kinetics and disproportionation property of Zr$_{0.8}$Ti$_{0.2}$Co.

1. Introduction

Because of the rapid decrease of fossil fuels and the increasingly serious environmental pollution in recent years, developing a clean and renewable energy has become an urgent task for mankind [1]. Under the development of ITER (International Thermonuclear Experimental Reactor), fusion energy, by burning the fuel of deuterium (D) and tritium (T) plasma, is regarded as one of the most ideal energy sources due to its huge energy release, abundant fuel resources, and low radioactivity [2–4]. In order to ensure the successful operation of fusion reactors, a viable, highly efficient, safe, and inexpensive hydrogen isotope storage method for D-T fuel is very necessary [5, 6].

In ITER, the D-T fuel is recommended to be stored as metal deuteride and tritide because solid-state hydrogen isotopes storage offers such advantages as safety, efficiency (higher bulk hydrogen storage density), and processing convenience over gas and liquid storage methods [7, 8]. Among several alternative hydrogen storage materials, an intermetallic compound of ZrCo is proposed as one of the most suitable candidates for tritium storage according to (1), since it possesses such excellent properties as low equilibrium hydrogen pressure and fast hydrogen absorption rate at room temperature, moderate temperature for hydrogen desorption to 100 kPa, and desirable features of safety like nonradioactivity, low pyrophoricity, and small volume expansion during hydrogen sorption cycles [9–14].

$$2\text{ZrCoH}_3 \rightleftharpoons 2\text{ZrCo} + 3\text{H}_2 \quad (1)$$

However, its serious degradation of hydrogen storage properties during the hydrogen sorption cycle obstructs its...
wide application, resulting from the concomitant hydrogen-induced disproportionation reaction that happened above 573 K during hydrogen sorption process shown as follows [15–18]:

$$2\text{ZrCo} + H_2 \rightarrow \text{ZrH}_2 + \text{ZrCo}_2 \quad (2a)$$

$$2\text{ZrCoH}_3 \rightarrow \text{ZrH}_2 + \text{ZrCo}_2 + 2H_2 \quad (2b)$$

Because of the high thermodynamic stabilities of $\text{ZrH}_2$ and $\text{ZrCo}_2$, the disproportionation of $\text{ZrCo}$ will cause significant degradation of hydrogen storage properties during the practical hydrogen sorption cycles [19].

Recently, many investigations focused on the element substitution have been made to improve the antidisproportionation property of $\text{ZrCo}$, which achieved remarkable progress [20–24]. Compared with other elements, Ti has been surprisingly found to be the most effective substitution element for improving the antidisproportionation property so far. Huang et al. [25] found that the equilibrium hydrogen desorption pressure of $\text{Zr}_{1-x}\text{Ti}_x\text{Co}$ alloy increases along with increasing Ti content. In the meantime, hydrogen sorption cycles do not produce separated $\text{ZrCo}$, $\text{TiCo}$, and $\text{ZrH}_2$, suggesting that the antidisproportionation property of $\text{ZrCo}$ alloy is improved by Ti substitution. Zhao et al. also confirmed that partial substitution of Ti for Zr will significantly enhance the antidisproportionation property of $\text{ZrCo}$ [26, 27]. Zhang et al. [28] systematically compared the effects of Ti substitution on the disproportionation behaviors of $\text{ZrCo}$ with Sc, Ni, and Fe elements. It was observed that Ti has superior effect on suppressing the disproportionation of $\text{ZrCo}$. Similar result was proved by Kou et al. who reported that $\text{Zr}_{0.8}\text{Ti}_{0.2}\text{Co}$ bed had better durability against disproportionation than $\text{ZrCo}$ bed and $\text{Zr}_{0.8}\text{H}_{0.2}\text{Co}$ bed [29].

Meanwhile, Jat et al. [30] further investigated the influences of Ti amount on the disproportionation rate of $\text{Zr}_{1-x}\text{Ti}_x\text{Co}$ alloy and found the disproportionation decreases in order of $\text{ZrCo} > \text{Zr}_{0.9}\text{Ti}_{0.1}\text{Co} > \text{Zr}_{0.9}\text{Ti}_{0.3}\text{Co} > \text{Zr}_{0.8}\text{Ti}_{0.2}\text{Co}$.

Although it seems that Ti-substituted $\text{ZrCo}$ alloy possesses the improved antidisproportionation property, the requirements of practical application still cannot be completely satisfied due to its stagnant hydrogen sorption kinetics. Zhao et al. [26] reported that the hydrogen absorption amount and rate of $\text{ZrCo}$ decrease with the Ti content increasing. Moreover, Shmayda et al. [31] and Yoo et al. [32] showed that the kinetic response of $\text{ZrCo}$ for hydrogen sorption is slower than uranium, which restricts the application of $\text{ZrCo}$ alloy. Therefore, it is of great necessity to further enhance the hydrogen sorption kinetics of Ti-substituted $\text{ZrCo}$ alloy.

It has extensively shown that mechanical ball milling is an effective technique for improving the kinetic property of hydrogen storage materials [33–36]. However, the effects of ball milling on the hydrogen sorption kinetics and microstructure of $\text{ZrCo}$-based alloy have never been investigated. In this paper, we focused on the effects of ball milling on microstructure and kinetic hydrogen sorption properties of $\text{Zr}_{0.8}\text{Ti}_{0.2}\text{Co}$ alloy. Furthermore, because study of kinetics is clearly beneficial to understanding of mechanism about hydrogen sorption process [20, 37, 38], kinetic analysis has also been carried out for disproportionation of $\text{Zr}_{0.8}\text{Ti}_{0.2}\text{Co}$ in this work.

2. Experimental

2.1. Sample Preparation and Kinetic Measurements. $\text{Zr}_{0.8}\text{Ti}_{0.2}\text{Co}$ powder with particle size of 2–4 μm was purchased from the General Research Institute for Nonferrous Metals (Beijing, China). The hydrogen sorption behaviors of the samples were investigated by a Sievert-type apparatus. The detailed activation procedures of $\text{Zr}_{0.8}\text{Ti}_{0.2}\text{Co}$ were performed according to [39]. The samples were prepared by ball milling of $\text{Zr}_{0.8}\text{Ti}_{0.2}\text{Co}$ powder using a planetary mill at 400 rpm for different time. After ball milling, the samples were firstly evacuated at 500°C, and then the hydrogen absorption measurements of samples were conducted at 100°C under 0.8 bar H₂. For each time, about 1 g sample was loaded in the reactor of the apparatus, and hydrogen pressure reduction of ~0.2 bar was achieved for hydrogenation. After hydrogenation, the hydrogen in the reactor was evacuated and then the dehydrogenation measurements of samples were carried out from room temperature to 500°C with heating rate of 5°C/min. After that, the isothermal disproportionation kinetics was examined at 500°C for more than 500 min. The change of hydrogen pressure (P) as a function of time was recorded from room temperature to the end of the isothermal period. During the whole dehydrogenation process, the initial hydrogen pressure was recorded as $P_i$ and the maximum addition of hydrogen pressure was denoted as $P_{max}$. As a result, the hydrogen desorption and disproportionation of the sample were quantified by formula as $(P - P_i)/P_{max}$.

2.2. Structural Characterizations. X-ray powder diffraction (XRD) method was used to characterize the crystal structures of $\text{Zr}_{0.8}\text{Ti}_{0.2}\text{Co}$ samples at different states on a DX2700B diffractometer with Cu Kα radiation, 40 kV, and 30 mA. The XRD patterns were recorded in steps of 0.02° (2θ) from 20° to 90° with a constant scanning rate of 0.6 s per step. For Rietveld refinement of lattice parameters, special XRD data was obtained by scanning rate of 1.8 s per step.

The morphology of the samples was studied by scanning electron microscope (SEM, Ultra55, CARL ZEISSNMTS GmbH) and the compositional analysis on surface was carried out using energy dispersive X-ray spectroscopy (EDS, Inca). Morphological observation inside the particle was carried out by Helios Nanolab 600i Focused Ion Beam (FIB) using beam energy of 20 keV and a beam current of 2.8 nA. The microstructure of the samples was investigated using high-resolution transmission electron microscopy (HRTEM, Libra 200, CARL ZEISS IRTS) with an accelerating voltage of 200 kV.

3. Results and Discussion

3.1. Hydrogen Absorption/Desorption Kinetics. Figure 1 represents the XRD patterns of activated $\text{Zr}_{0.8}\text{Ti}_{0.2}\text{Co}$ samples after ball milling for different time. It can be found that $\text{Zr}_{0.8}\text{Ti}_{0.2}\text{Co}$ samples still keep $\text{ZrCo}$ phase except for trace
amount decreases with increasing ball milling time. The hydrogenation amount reaches 1.97 wt.% for the sample without ball milling, whereas the total hydrogen amount of only 0.50 wt.% can be obtained for the sample ball milled for 8 h. Meanwhile, the hydrogen absorption rate also exhibits a tendency to slow down after ball milling.

The dehydrogenation curves of ball milled Zr$_{0.8}$Ti$_{0.2}$Co samples after hydrogenation are shown in Figure 3. According to (2a) and (2b), the disproportionation reaction displayed by (2b) only happens under high hydrogen pressure. However, the hydrogen pressure is lower than 1 bar in this study. Therefore, the disproportionation of Zr$_{0.8}$Ti$_{0.2}$Co sample only takes place according to (2a) in this work, which causes the reduction in hydrogen pressure. As a result, the whole hydrogen desorption curve in Figure 3 can be divided into two stages, respectively, belonging to the temperature programmed dehydrogenation process (Figure 3(c)) and the disproportionation process (Figure 3(b)). It can be observed from the first stage that the hydrogen desorption rate is enhanced with increasing ball milling time, which is beneficial to practical application of ZrCo-based alloy. The second stage substantially represents an isothermal disproportionation process at 500°C. It can be seen that the disproportionation extent is very slight and the disproportionation rate is slow for all samples at 500°C, which is very close to the result reported by Zhang et al. [28]. Nevertheless, it is readily discernible that the disproportionation rate and extent monotonously grow with increasing ball milling time. These results suggest that not only the dehydrogenation rate but also the disproportionation rate of Zr$_{0.8}$Ti$_{0.2}$Co can be quickened by ball milling, the mechanism of which will be specifically discussed below.

Figure 4 demonstrates XRD patterns of the ball milled Zr$_{0.8}$Ti$_{0.2}$Co samples after disproportionation shown in Figure 3. It can be seen that the diffraction peaks corresponding to ZrCo phase are clearly present in all samples, though the intensity of ZrCo peaks decreases slightly with increasing ball milling time. The existence of major phase of ZrCo illustrates that the dehydrogenation mainly proceeds according (1). In addition, the weak diffraction peaks of disproportionation products including ZrH$_2$ and ZrCo$_2$ can be carefully observed, indicating the disproportionation extent of Zr$_{0.8}$Ti$_{0.2}$Co sample should be small. The intensity of diffraction peaks for ZrH$_2$ and ZrCo$_2$ is well in agreement with the disproportionation behaviors displayed in Figure 3, which shows minor reduction in hydrogen pressure.

3.2. Structural Characterization and Kinetic Mechanism. From the results above, it can be found that the hydrogen desorption kinetics and disproportionation kinetics of Zr$_{0.8}$Ti$_{0.2}$Co become faster, while the hydrogenation kinetics is restrained by ball milling. To comprehend these kinetic behaviors, detailed structural characterizations were performed. Firstly, the phase structure variation after ball milling has been investigated. To determine the lattice parameters of Zr$_{0.8}$Ti$_{0.2}$Co samples as accurately as possible, special XRD experiments have been performed to obtain strong diffraction signal by increasing the scanning time. According to the XRD results, the lattice parameters of the samples have been calculated by Rietveld refinement of XRD data via Jade.
Figure 3: Dehydrogenation curves (a), enlarged dehydrogenation curves (b), and enlarged disproportionation curves (c) of Zr$_{0.8}$Ti$_{0.2}$Co samples ball milled for different time. (i) 0 h; (ii) 2 h; (iii) 4 h; (iv) 6 h; (v) 8 h.

The representative Rietveld refinement pattern of Zr$_{0.8}$Ti$_{0.2}$Co sample is shown in Figure 5. The refinement result shows that the crystal structure of Zr$_{0.8}$Ti$_{0.2}$Co sample without ball milling is CsCl-type cubic (bcc) with lattice parameter $a = 3.1638$ Å, which is in good agreement with other study [28]. According to the specific Rietveld refinement results as displayed in Table 1, the lattice parameter and cell volume of Zr$_{0.8}$Ti$_{0.2}$Co sample slightly and continuously decrease with increasing ball milling time, which may be probably attributed to cumulative plastic deformation and microstrain in the crystal lattice during the ball milling process [33, 40]. In view of the variation of lattice parameter, it is easy to understand the kinetic performances of Zr$_{0.8}$Ti$_{0.2}$Co after ball milling. When the lattice parameter and cell volume become smaller, the occupancy of H atom in interstitial sites will become more difficult but release of H atom from interstitial sites will be easier [41]. Hence, it is observed that hydrogen absorption kinetics decreases but hydrogen desorption kinetics increases for Zr$_{0.8}$Ti$_{0.2}$Co with increasing ball milling time.

To investigate the morphologies of ball milled Zr$_{0.8}$Ti$_{0.2}$Co samples, SEM analysis has been performed and...

![Figure 5: Rietveld refinement of X-ray diffraction pattern of Zr_{0.8}Ti_{0.2}Co sample without ball milling.](image)

The results are shown in Figure 6. After ball milling, the morphologies of Zr_{0.8}Ti_{0.2}Co sample tend to be small particles from initial chip. Meanwhile, the particle size gradually decreases with increasing the ball milling time. Besides, as the ball milling time increases, the agglomeration of particles is distinctly reduced and the particles become more dispersible.

Furthermore, in order to closely observe the surface of the samples, the SEM images of the ball milled Zr_{0.8}Ti_{0.2}Co samples at magnification of 10000x were obtained, as shown in Figure 7. A lot of chips and sharp edges are observed for the sample without ball milling. However, the sharp edges can hardly be observed on the surface of ball milled Zr_{0.8}Ti_{0.2}Co sample, which should be caused by deformation and compaction during the ball milling process. It is well known that the edges are apt to break off and fresh surface will emerge in the process of hydrogenation [42, 43], which is beneficial to enhancement of hydrogen absorption. Moreover, as a direct and fast diffusion path of hydrogen, the edges are also beneficial to fast hydrogen absorption [44]. Hence, the change in morphology is mainly responsible for the decrease of hydrogen absorption kinetics for Zr_{0.8}Ti_{0.2}Co samples after ball milling.

In order to analyze the composition of the sample surface, two representative EDS spectrums of every sample over the surface were obtained, as shown in Figure 8. The detailed elemental contents for every sample are listed in Table 2. It is interesting to discover that the existence of Fe element on the surface of particles is detected for all ball milled Zr_{0.8}Ti_{0.2}Co samples. This suggests that the Fe element may be brought by steel milling vessel and balls during the ball milling process [38]. It has been reported that the disproportionation of ZrCo will be accelerated after doping Fe [22, 28]. Hence, it is reasonable to believe that faster disproportionation rate of ball milled Zr_{0.8}Ti_{0.2}Co samples has direct correlation with the introduced Fe element on the surface of particles. Besides, it can be found that the average atom ratio of (Zr + Ti)/(Co + Fe) for the selected regions decreases gradually from 0.89 to 0.66 when the ball milling time extends from 0 h to 8 h. As previous studies proved, when the average atom ratio of Zr : Co is much closer to 0.5 (1:2), the elemental recombination of ZrCo\textsubscript{2} phase will be facilitated during the disproportionation process [45, 46]. Consequently, disproportionation of ZrCo is aggravated. Due to the analogical feature of group element, the substitution element of Ti and introduced Fe can, respectively, be included in Zr and Co. As a result, the gradual decrease of ((Zr + Ti)/(Co + Fe) from 0.89 to 0.66 may be another reason that aggravates the disproportionation of Zr_{0.8}Ti_{0.2}Co sample by increasing ball milling time, as shown in Figure 3.
In order to further characterize the microstructure, the TEM analysis for $\text{Zr}_{0.8}\text{Ti}_{0.2}\text{Co}$ samples ball milled for 8 h has been employed and the results are shown in Figure 9. Figures 9(b) and 9(c), respectively, show enlarged TEM images and corresponding SAED patterns of zones 1 and 2 in Figure 9(a). It can be found from the SAED patterns that the $\text{Zr}_{0.8}\text{Ti}_{0.2}\text{Co}$ particle ball milled for 8 h is comprised of not only polycrystalline regions but also a number of amorphous regions. In accordance with PDF number 030657272, the interplanar distances of 0.218 nm, 0.218 nm, and 0.219 nm in Figure 9(b) all correspond to $\{110\}$ planes of $\text{Zr}_{0.8}\text{Ti}_{0.2}\text{Co}$. According to Figure 5, the interplanar distance of $\{110\}$ should be 0.224 nm for $\text{Zr}_{0.8}\text{Ti}_{0.2}\text{Co}$ sample without ball milling. It is clear that the interplanar distance of $\{110\}$ has been shortened to be about 0.218 nm after ball milling for 8 h. It is suggested that the lattice parameter of $\text{Zr}_{0.8}\text{Ti}_{0.2}\text{Co}$ sample was decreased after ball milling, which is in good agreement with the Rietveld refinement results of XRD. Moreover, a number of amorphous regions (over yellow line) are clearly observed in Figure 9(c). Meanwhile, a large number of defects including dislocations and grain boundaries (around green line) are widely observed, which provide a possible explanation for the broadened XRD patterns shown in Figure 1. As well known, these disordered microstructures mentioned above are favorable for H atom diffusion instead of occupation [38, 47]. Therefore, the reduction of the hydrogenation amount and enhancement of the dehydrogenation rate for ball milled $\text{Zr}_{0.8}\text{Ti}_{0.2}\text{Co}$ samples are probably resulting from the disordered microstructures produced during the ball milling process.

**Figure 6**: SEM images of the $\text{Zr}_{0.8}\text{Ti}_{0.2}\text{Co}$ samples ball milled for different time. (a) 0 h; (b) 2 h; (c) 4 h; (d) 6 h; (e) 8 h.
3.3. Kinetic Model Analysis. In order to further understand the disproportionation kinetic mechanism, the kinetic analysis of disproportionation has been performed for ball milled Zr$_{0.8}$Ti$_{0.2}$Co. Usually, the relationship between the reacted fraction and reaction time is linear for surface reaction controlled step [48, 49]. According to Figure 3, it can be found that the disproportionation curves of all Zr$_{0.8}$Ti$_{0.2}$Co samples should just represent the initial stage of whole disproportionation and the reaction equilibrium has not been reached within 450 min at 500°C. Moreover, the disproportionation kinetics of all Zr$_{0.8}$Ti$_{0.2}$Co samples in this stage is clearly inclined to be linear. Thus, the isothermal disproportionation data of Zr$_{0.8}$Ti$_{0.2}$Co sample after ball milling for different time has been linearly fitted, as shown in Figure 10. It can be seen from the fitting results that the disproportionation kinetics of Zr$_{0.8}$Ti$_{0.2}$Co samples is much closer to linear with increasing the ball milling time. Meanwhile, the slope of fitted line is slightly decreased, corresponding to the slight aggravation of disproportionation rate. The well-fitted linear results suggest that the disproportionation stage of Zr$_{0.8}$Ti$_{0.2}$Co samples curved by Figure 3 should be a surface reaction controlled step.

Based on the results of microstructure and kinetic analysis above, some useful insights can be obtained into the mechanism of hydrogen sorption reaction and disproportionation reaction for ball milled Zr$_{0.8}$Ti$_{0.2}$Co samples. The effects of ball milling on the hydrogen sorption and disproportionation behaviors of Zr$_{0.8}$Ti$_{0.2}$Co sample can be deduced from the changed microstructure including lattice parameter, morphology, elemental composition, and crystal defects. ---
hydrogen sorption reaction, it can be found that ball milling shows negative effect on the hydrogen absorption rate of $\text{Zr}_{0.8}\text{Ti}_{0.2}\text{Co}$ sample, which is different from the commonly positive effects of ball milling on hydrogen storage materials in many studies. The negative effects of ball milling may be resulting from three aspects: (1) the decreased cell volume makes the entering of hydrogen atom into interstitial site in lattice more difficult; (2) the missing sharp edges of particles cut the paths for fast transfer of hydrogen; (3) the increased disorderliness of microstructure goes against the occupation of hydrogen. As a result, it was observed that the hydrogen absorption rate and amount of $\text{Zr}_{0.8}\text{Ti}_{0.2}\text{Co}$ sample were decreased by increasing ball milling. On the other hand, it can be found that the ball milling plays a positive role in hydrogen desorption rate. The positive effects of ball milling may be derived from three points: (1) the decreased cell volume results in the fact that H atoms begin to be less-stable in the crystal lattice and are inclined to leave from crystal interstitial sites; (2) the introduced Fe on the surface may act as catalysts for hydrogen dissociation [50]; (3) the produced lattice defects like dislocations and grain boundaries possibly act as a pathway for hydrogen transportation during dehydrogenation [51, 52]. Consequently, it was seen that the hydrogen desorption rate was increased by ball milling.

For disproportionation reaction, it is found the disproportionation rate of $\text{Zr}_{0.8}\text{Ti}_{0.2}\text{Co}$ sample was exacerbated by ball milling. According to the kinetic analysis, the disproportionation stage of $\text{Zr}_{0.8}\text{Ti}_{0.2}\text{Co}$ in this work should be a surface reaction controlled step, indicating that the surface state is very important for the disproportionation.

As mentioned in the analysis of EDS results, Fe element was introduced during the ball milling process on the surface of \( \text{Zr}_{0.8}\text{Ti}_{0.2}\text{Co} \) particles, resulting in the gradual decrease of \( (\text{Zr} + \text{Ti})/(\text{Co} + \text{Fe}) \). This possibly facilitates the elemental recombination of \( \text{ZrCo}_2 \) phase. So, it is observed that the ball milled \( \text{Zr}_{0.8}\text{Ti}_{0.2}\text{Co} \) owns faster disproportionation kinetics. On the other hand, it is found from the microstructure that considerable crystal defects and strain energy were formed after ball milling, especially on the surface. It is well known that the crystal defects and strain energy will
facilitate the transfer process of hydrogen atoms during hydrogen sorption reaction, which may be also beneficial for promoting the transfer of hydrogen atom from ZrCo to form ZrH2. Consequently, it is observed that the rate of the initial disproportionation stage for Zr0.8Ti0.2Co is enhanced by ball milling. In conclusion, if Zr0.8Ti0.2Co is expected to not only own fast hydrogen sorption kinetics but also have good antidispersion, it may be a good way to prepare Zr0.8Ti0.2Co as fine powder with smaller lattice parameter, uniform element distribution, and orderly microstructure and without impurity.

4. Conclusion

In summary, the effects of ball milling on the hydrogen sorption properties and microstructure of Zr0.8Ti0.2Co have been investigated systematically. Experimental results show that hydrogen absorption kinetics of Zr0.8Ti0.2Co decreases and the hydrogen desorption kinetics accelerates with increasing the ball milling time. Meanwhile, the disproportionation rate of Zr0.8Ti0.2Co is aggravated after ball milling. Characterizations of microstructure reveal that the variation of hydrogen sorption kinetics of Zr0.8Ti0.2Co after ball milling is mainly resulting from the changed microstructure including lattice parameter, morphology, elemental composition, and crystal defects. Kinetic analysis reveals that the initial stage of disproportionation for Zr0.8Ti0.2Co is a surface step controlled reaction. And the slight aggravation of disproportionation rate may be attributed to the introduced Fe on the surface of particles and the crystal defects together with strain energy after ball milling.

Conflicts of Interest

The authors declare that they have no conflicts of interest.
