STATIONARY SOLUTIONS OF STOCHASTIC PARTIAL DIFFERENTIAL EQUATIONS IN THE SPACE OF TEMPERED DISTRIBUTIONS

SUPRIO BHAR

Abstract. In Rajeev (2013), “Translation invariant diffusion in the space of tempered distributions”, it was shown that there is an one to one correspondence between solutions of a class of finite dimensional SDEs and solutions of a class of SPDEs in $S'$, the space of tempered distributions, driven by the same Brownian motion. There the coefficients $\bar{\sigma}, \bar{b}$ of the finite dimensional SDEs were related to the coefficients of the SPDEs in $S'$ in a special way, viz. through convolution with the initial value $y$ of the SPDEs.

In this paper, we consider the situation where the solutions of the finite dimensional SDEs are stationary and ask whether the corresponding solutions of the equations in $S'$ are also stationary. We provide an affirmative answer, when the initial random variable takes value in a certain set $\mathcal{C}$, which ensures that the coefficients of the finite dimensional SDEs are related to the coefficients of the SPDEs in the above ‘special’ manner.

1. Introduction

The topology of infinite dimensional spaces plays a major role in the study of stochastic differential equations in those spaces. These topological vector spaces are usually taken to be countably Hilbertian Nuclear spaces (see [14, 16]) and in particular real separable Hilbert spaces (see [3, 4, 9]). In [21], a correspondence was shown between finite dimensional stochastic differential equations and stochastic partial differential equations in $S'({\mathbb{R}}^d)$ (where $S'({\mathbb{R}}^d)$ denotes the space of tempered distributions) via an Itô formula. The results there involves deterministic initial conditions. In this paper we extend this correspondence to random initial conditions taking values in some Hermite Sobolev space $S_p({\mathbb{R}}^d)$. Assuming the existence of stationary solutions of finite dimensional stochastic differential equations, we then show the existence of stationary solutions of infinite dimensional stochastic partial differential equations, via an Itô formula which is used in proving the correspondence.

Let $(\Omega, \mathcal{F}, (\mathcal{F}_t), P)$ be a filtered complete probability space satisfying the usual conditions. Let $\{B_t\}$ be a $d$ dimensional $(\mathcal{F}_t)$ standard Brownian motion. By $(\mathcal{F}_t^B)$ we denote the filtration generated by $\{B_t\}$. Let $\delta$ be an arbitrary state, viewed as an isolated point of $S_p({\mathbb{R}}^d) := S_p({\mathbb{R}}^d) \cup \{\delta\}$. For an initial condition $\psi \in S_p({\mathbb{R}}^d)$, consider the stochastic partial differential equation

\begin{equation}
\frac{dY_t}{dt} = A(Y_t) \, dB_t + L(Y_t) \, dt; \quad Y_0 = \psi,
\end{equation}

Key words and phrases. Stationary solutions, Invariant measures, Diffusion processes, Stochastic differential equations, $S'$ valued processes.
where

(i) the operators $A := (A_1, \cdots, A_d)$, $L$ on $S_p(\mathbb{R}^d)$ as follows: for $\phi \in S_p(\mathbb{R}^d)$

$$A_1 \phi := -\sum_{j=1}^{d} \langle \sigma_j, \phi \rangle \partial_j \phi, \quad i = 1, \cdots, d$$

(1.2)

and

$$L \phi := \frac{1}{2} \sum_{i,j=1}^{d} \langle (\sigma, \phi) (\sigma, \phi)' \rangle_{ij} \partial^2_{ij} \phi - \sum_{i=1}^{d} \langle b, \phi \rangle_i \partial_i \phi,$$

(1.3)

(ii) $\sigma = (\sigma_{ij})_{d \times d}, b = (b_1, b_2, \cdots, b_d)$ with $\sigma_{ij}, b_i \in S_p(\mathbb{R}^d)$ for $i, j = 1, 2, \cdots, d$.

For any $\phi \in S_p(\mathbb{R}^d)$, by $\langle \sigma, \phi \rangle$ we denote the $d \times d$ matrix with entries $\langle \sigma, \phi \rangle_{ij} := \langle \sigma_{ij}, \phi \rangle$. Similarly $\langle b, \phi \rangle$ is a vector in $\mathbb{R}^d$ with $\langle b, \phi \rangle_i := \langle b_i, \phi \rangle$.

Given $\psi \in S_p(\mathbb{R}^d)$, let $\bar{\sigma} \cdot \psi : \mathbb{R}^d \rightarrow \mathbb{R}^d$ and $\bar{b} \cdot \psi : \mathbb{R}^d \rightarrow \mathbb{R}^d$ be the following functions $\bar{\sigma}(x; \psi) := \langle (\sigma_{ij}, \tau_x \psi) \rangle$ and $\bar{b}(x; \psi) := \langle (b_i, \tau_x \psi) \rangle$. Let $\tau_x, x \in \mathbb{R}^d$ denote the translation operators (see Section 2). The next result is about the existence and uniqueness of a strong solution of (1.1).

**Theorem 1.1** ([21] Theorem 3.4 and Lemma 3.6). Let $\psi, \sigma_{ij}, b_i, \{B_t\}$ be as above. Suppose that the functions $x \mapsto \bar{\sigma}(x; \psi)$ and $x \mapsto \bar{b}(x; \psi)$ are locally Lipschitz. Then equation (1.1) has a unique $S_p(\mathbb{R}^d)$ valued $(\mathcal{F}_t^B)$ adapted strong local solution given by

$$Y_t = \tau_{Z_t}(\psi), \quad \text{for } 0 \leq t < \eta,$$

where $\eta$ is an $(\mathcal{F}_t^B)$ adapted stopping time and $\{Z_t\}$ solves the stochastic differential equation

$$dZ_t = \bar{\sigma}(Z_t; \psi) \cdot dB_t + \bar{b}(Z_t; \psi) \cdot dt; \quad Z_0 = 0.$$

(1.4)

In this paper, we use the same techniques as those used in [21]. In Section 2, we list basic properties of Hermite Sobolev spaces which are used throughout the paper. In Section 3, we extend the Itô formula [20, Theorem 2.3] to Theorem 3.2 involving random initial condition and prove existence and uniqueness results for the solutions of finite dimensional stochastic differential equation (3.7) (see Theorem 3.3 and Theorem 3.6). These results allow us to extend the said correspondence (see Theorem 3.12 and Lemma 3.13). Note that the equation for $Z$ involves the initial condition for $Y$ i.e. $Y_0$, but with $Z_0 = 0$. To discuss existence and uniqueness for $Z$, we use 'Lipschitz' criteria, which depends on $Y_0$. We need control on the norm of $Y_0$ to make the usual proof via Picard iteration work. In Proposition 3.14 and Proposition 3.15 we prove $L^2$ estimates on the supremum of the norms of the solutions of (3.1), in terms of the initial condition. In Section 4, we define a subset $C$ of the Hermite Sobolev space with the following property: if the initial random variables takes values in the set $C$, then the associated finite dimensional stochastic differential equations are all the same. This property is observed in Lemma 4.1 and using which we show the existence of stationary solutions of stochastic partial differential equations in our class (Theorem 4.3). To guarantee non-explosion for finite dimensional stochastic differential equations with locally Lipschitz coefficients, we use a 'Liapunov' type criteria ([25, 7.3.14 Corollary]). Two examples of stationary solutions are given in Example 4.5 and
in Proposition 1.6 we obtain $\mathcal{L}^1$ estimates on the supremum of the norms of the stationary solutions, in terms of the initial condition.

2. Topologies on $\mathcal{S}$ and $\mathcal{S}'$

Let $\mathcal{S}(\mathbb{R}^d)$ be the space of smooth rapidly decreasing $\mathbb{R}$-valued functions on $\mathbb{R}^d$ with the topology given by L. Schwartz (see [27]) and let $\mathcal{S}'(\mathbb{R}^d)$ be the dual space, known as the space of tempered distributions. For any $p \in \mathbb{R}$, let $\mathcal{S}_p(\mathbb{R}^d)$ be the completion of $\mathcal{S}(\mathbb{R}^d)$ in the inner product $\langle \cdot, \cdot \rangle_p$ which is defined in terms of the $\mathcal{L}^2(\mathbb{R}^d)$ inner product (see [14] Chapter 1.3 for the details). The spaces $\mathcal{S}_p(\mathbb{R}^d), p \in \mathbb{R}$ are separable Hilbert spaces and are known as the Hermite-Sobolev spaces. We write $\mathcal{S}, \mathcal{S}', \mathcal{S}_p$ instead of $\mathcal{S}(\mathbb{R}), \mathcal{S}'(\mathbb{R}), \mathcal{S}_p(\mathbb{R})$.

Note that $\mathcal{S}_0(\mathbb{R}^d) = \mathcal{L}^2(\mathbb{R}^d)$ and for $p > 0$, $\mathcal{S}_p(\mathbb{R}^d) \subset \mathcal{L}^2(\mathbb{R}^d)$ (i.e. these distributions are given by functions) and $(\mathcal{S}_p(\mathbb{R}^d), \| \cdot \|_p)$ is dual to $(\mathcal{S}_p(\mathbb{R}^d), \| \cdot \|_p)$.

Furthermore,

$$\mathcal{S}(\mathbb{R}^d) = \bigcap_{p \in \mathbb{R}} (\mathcal{S}_p(\mathbb{R}^d), \| \cdot \|_p), \quad \mathcal{S}'(\mathbb{R}^d) = \bigcup_{p \in \mathbb{R}} (\mathcal{S}_p(\mathbb{R}^d), \| \cdot \|_p)$$

Given $\psi \in \mathcal{S}(\mathbb{R}^d)$ (or $\mathcal{S}_p(\mathbb{R}^d)$) and $\phi \in \mathcal{S}'(\mathbb{R}^d)$ (or $\mathcal{S}_p(\mathbb{R}^d)$), the action of $\phi$ on $\psi$ will be denoted by $\langle \phi, \psi \rangle$.

Let $\{h_n : n \in \mathbb{Z}_+^d\}$ be the Hermite functions (see [14] Chapter 1.3), where $\mathbb{Z}_+^d := \{n = (n_1, \cdots, n_d) : n_i \text{ non-negative integers}\}$. If $n = (n_1, \cdots, n_d)$, we define $|n| := n_1 + \cdots + n_d$. Note that $\{h_n^p : n \in \mathbb{Z}_+^d\}$ forms an orthonormal basis for $\mathcal{S}_p(\mathbb{R}^d)$, where $h_n^p := (2|n| + d)^{p/2} h_n$.

Consider the derivative maps denoted by $\partial_i : \mathcal{S}(\mathbb{R}^d) \to \mathcal{S}(\mathbb{R}^d)$ for $i = 1, \cdots, d$. We can extend these maps by duality to $\partial_i : \mathcal{S}'(\mathbb{R}^d) \to \mathcal{S}'(\mathbb{R}^d)$ as follows: for $\psi \in \mathcal{S}'(\mathbb{R}^d)$,

$$\langle \partial_i \psi, \phi \rangle := -\langle \psi, \partial_i \phi \rangle, \quad \forall \phi \in \mathcal{S}(\mathbb{R}^d).$$

Let $\{e_i : i = 1, \cdots, d\}$ be the standard basis vectors in $\mathbb{R}^d$. Then for any $n = (n_1, \cdots, n_d) \in \mathbb{Z}_+^d$ we have (see [12] Appendix A.5)

$$\partial_i h_n = \sqrt{\frac{n_i}{2}} h_{n-e_i} - \sqrt{\frac{n_i + 1}{2}} h_{n+e_i},$$

with the convention that for a multi-index $n = (n_1, \cdots, n_d)$, if $n_i < 0$ for some $i$, then $h_n \equiv 0$. Above recurrence implies that $\partial_i : \mathcal{S}_p(\mathbb{R}^d) \to \mathcal{S}_{p-1}(\mathbb{R}^d)$ is a bounded linear operator.

For $x \in \mathbb{R}^d$, let $\tau_x$ denote the translation operators on $\mathcal{S}(\mathbb{R}^d)$ defined by $\tau_x \phi(y) := \phi(y - x), \forall y \in \mathbb{R}^d$. This operators can be extended to $\tau_x : \mathcal{S}'(\mathbb{R}^d) \to \mathcal{S}'(\mathbb{R}^d)$ by

$$\langle \tau_x \phi, \psi \rangle := \langle \phi, \tau_{-x} \psi \rangle, \quad \forall \phi, \psi \in \mathcal{S}(\mathbb{R}^d).$$

Lemma 2.1. The translation operators $\tau_x, x \in \mathbb{R}^d$ have the following properties:

(a) ([22] Theorem 2.1) For $x \in \mathbb{R}^d$ and any $p \in \mathbb{R}$, $\tau_x : \mathcal{S}_p(\mathbb{R}^d) \to \mathcal{S}_p(\mathbb{R}^d)$ is a bounded linear map. In particular, there exists a real polynomial $P_k$ of degree $k = 2(|p| + 1)$ such that

$$\|\tau_x \phi\|_p \leq P_k(|x|) \|\phi\|_p, \forall \phi \in \mathcal{S}_p(\mathbb{R}^d),$$

where $|x|$ denotes the standard Euclidean norm of $x$.

(b) For $x \in \mathbb{R}^d$ and any $i = 1, \cdots, d$ we have $\tau_x \partial_i = \partial_i \tau_x$.

(c) Fix $\phi \in \mathcal{S}_p(\mathbb{R}^d)$. Then $x \mapsto \tau_x \phi$ is continuous.
Proof. Part (b) can be verified for elements of $\mathcal{S}(\mathbb{R}^d)$ first and then can be extended to elements of $\mathcal{S}'(\mathbb{R}^d)$ via duality.

Proof of part (c) is contained in the proof of \[23\] Proposition 3.1. □

On $\mathcal{S}(\mathbb{R}^d)$ consider the multiplication operators $M_i, i = 1, \cdots, d$ defined by

$$(M_i\phi)(x) := x_i\phi(x), \phi \in \mathcal{S}(\mathbb{R}^d), x = (x_1, \cdots, x_d) \in \mathbb{R}^d.$$  

By duality these operators can be extended to $M_i : \mathcal{S}'(\mathbb{R}^d) \rightarrow \mathcal{S}'(\mathbb{R}^d)$. Note that $x_i h_n(x) = \sqrt{\frac{n+1}{n}} h_{n+\epsilon_i}(x) + \sqrt{\frac{n}{n+1}} h_{n-\epsilon_i}(x)$ (see \[12\] Appendix A.5, equation (A.26)) and hence $M_i : \mathcal{S}_p(\mathbb{R}^d) \rightarrow \mathcal{S}_{p-\frac{1}{d}}(\mathbb{R}^d)$ is a bounded linear operator, for any $p \in \mathbb{R}$. For dimension $d = 1$, we write $M_x$ instead of $M_1$.

3. Stochastic Differential Equations in $\mathcal{S}'$

We use the following terminology and notation. We say $\{\sigma_n\}$ is a localizing sequence, if each $\sigma_n$ is an $(\mathcal{F}_t)$ stopping time with $\sigma_n \uparrow \infty$. We use stochastic integration in the Hilbert spaces $\mathcal{S}_p(\mathbb{R}^d)$ (as in \[21\]). $\mathcal{S}_p(\mathbb{R}^d)$ valued stochastic integrals $\int_0^t G_s dX_s$ can be defined for $\mathcal{S}_p(\mathbb{R}^d)$ valued predictable, locally norm-bounded processes $\{G_t\}$ and real semimartingales $\{X_t\}$. For any $x \in \mathbb{R}^n$, by $|x|$ we denote the standard Euclidean norm of $x$. The dimension will be clear from the context where this notation is used.

3.1. Random Initial Conditions. Let $\xi$ be an $\mathcal{S}_p(\mathbb{R}^d)$ valued $\mathcal{F}_0$ measurable random variable. Now consider the stochastic partial differential equation

$$d Y_t = A(Y_t) \, dB_t + L(Y_t) \, dt; \quad Y_0 = \xi. \quad (3.1)$$

We want to extend the results of \[21\] Section 3 to the case of $\mathcal{S}_p(\mathbb{R}^d)$ valued random initial conditions. We have the following Itô formula (see \[20\] Theorem 2.3).

Proposition 3.1. Let $p \in \mathbb{R}$ and $\phi \in \mathcal{S}_{-p}(\mathbb{R}^d)$. Let $X = (X^1, \cdots, X^d)$ be an $\mathbb{R}^d$ valued continuous $(\mathcal{F}_t)$ adapted semimartingale. Then we have the following equality in $\mathcal{S}_{-p-1}(\mathbb{R}^d)$, a.s.

$$(3.2) \quad \tau_X \phi = \tau_{X_0} \phi - \sum_{i=1}^d \int_0^t \partial_i \tau_X \phi \, dX^i_s + \frac{1}{2} \sum_{i,j=1}^d \int_0^t \partial_{ij}^2 \tau_X \phi \, d[X^i, X^j]_s, \forall t \geq 0.$$  

We need to extend above result to allow random $\phi$.

Theorem 3.2. Let $p \in \mathbb{R}$. Let $\xi$ be an $\mathcal{S}_p(\mathbb{R}^d)$ valued $\mathcal{F}_0$ measurable random variable with $\mathbb{E}[\|\xi\|_p^2] < \infty$. Let $X = (X^1, \cdots, X^d)$ be an $\mathbb{R}^d$ valued continuous semimartingale. Then we have the following equality in $\mathcal{S}_{-p-1}(\mathbb{R}^d)$, a.s.

$$(3.3) \quad \tau_X \xi = \tau_{X_0} \xi - \sum_{i=1}^d \int_0^t \partial_i \tau_X \xi \, dX^i_s + \frac{1}{2} \sum_{i,j=1}^d \int_0^t \partial_{ij}^2 \tau_X \xi \, d[X^i, X^j]_s, \forall t \geq 0.$$  

Proof. Fix $\phi \in \mathcal{S}(\mathbb{R}^d)$. Then $\phi \in \mathcal{S}_{-p+1}(\mathbb{R}^d)$ and by the previous Proposition, we have in $\mathcal{S}_{-p}(\mathbb{R}^d)$ a.s. for all $t \geq 0$

$$\tau_{-X} \phi = \tau_{-X_0} \phi + \sum_{i=1}^d \int_0^t \partial_i \tau_{-X} \phi \, dX^i_s + \frac{1}{2} \sum_{i,j=1}^d \int_0^t \partial_{ij}^2 \tau_{-X} \phi \, d[X^i, X^j]_s.$$  

Then a.s.
\[
\langle \xi, \tau_{-X_0} \phi \rangle = \langle \xi, \tau_{-X} \phi \rangle + \left\langle \xi, \sum_{i=1}^{d} \int_{0}^{t} \partial_i \tau_{-X} \phi \, dX_s^i \right\rangle \\
+ \left\langle \xi, \frac{1}{2} \sum_{i,j=1}^{d} \int_{0}^{t} \partial_{ij} \tau_{-X} \phi \, d[X^i, X^j]_s \right\rangle, \forall t \geq 0.
\]
(3.4)

Now using \[20\] Proposition 1.3(a) and Lemma 24(b) we can show
\[
\left\langle \xi, \sum_{i=1}^{d} \int_{0}^{t} \partial_i \tau_{-X} \phi \, dX_s^i \right\rangle = \left\langle - \sum_{i=1}^{d} \int_{0}^{t} \partial_i \tau_X \phi \, dX_s^i, \phi \right\rangle
\]
and
\[
\left\langle \xi, \frac{1}{2} \sum_{i,j=1}^{d} \int_{0}^{t} \partial_{ij} \tau_{-X} \phi \, d[X^i, X^j]_s \right\rangle = \left\langle \frac{1}{2} \sum_{i,j=1}^{d} \int_{0}^{t} \partial_{ij} \tau_X \phi \, d[X^i, X^j]_s, \phi \right\rangle.
\]

Using \[33\] we get a \(P\)-null set \(\mathcal{N}\) such that for \(\omega \in \Omega \setminus \mathcal{N}\) and for any multi-index \(n = (n_1, \ldots, n_d)\) we have
\[
\langle \tau_{X_n} \xi, h_n \rangle = \langle \tau_{X_0} \xi, h_n \rangle - \sum_{i=1}^{d} \int_{0}^{t} \partial_i \tau_{X_0} \xi \, dX_s^i, h_n \rangle \\
+ \left\langle \frac{1}{2} \sum_{i,j=1}^{d} \int_{0}^{t} \partial_{ij} \tau_{X_0} \xi \, d[X^i, X^j]_s, h_n \right\rangle, \forall t \geq 0.
\]

where \(h_n\) are the Hermite functions which form a total set in \(\mathcal{S}_{p-1}(\mathbb{R}^d)\). Since \(
\{\tau_{X_n} \xi - \tau_{X_0} \xi + \sum_{i=1}^{d} \int_{0}^{t} \partial_i \tau_{X_0} \xi \, dX_s^i - \frac{1}{2} \sum_{i,j=1}^{d} \int_{0}^{t} \partial_{ij} \tau_{X_0} \xi \, d[X^i, X^j]_s\}\) is an \(\mathcal{S}_{p-1}(\mathbb{R}^d)\) valued process, we have the equality in \(\mathcal{S}_{p-1}(\mathbb{R}^d)\) a.s.
\[
\tau_{X_n} \xi - \tau_{X_0} \xi + \sum_{i=1}^{d} \int_{0}^{t} \partial_i \tau_{X_0} \xi \, dX_s^i - \frac{1}{2} \sum_{i,j=1}^{d} \int_{0}^{t} \partial_{ij} \tau_{X_0} \xi \, d[X^i, X^j]_s = 0, t \geq 0.
\]

This completes the proof. \(\square\)

**Alternative proof of Theorem 3.2** We make two observations, including a property of stochastic integrals, viz. \[3.3\].

(a) Given any \(\mathcal{F}_0\) measurable set \(F\), an \(\mathcal{S}_p(\mathbb{R}^d)\) valued predictable step process \(\{G_t\}\) and a continuous \(\mathbb{R}^d\) valued semimartingale \(\{X_t\}\), we have a.s.
\[
1_F \int_{0}^{t} G_s \, dX_s = \int_{0}^{t} 1_F G_s \, dX_s, \, t \geq 0.
\]
(3.5)

Above equality can be extended to the case involving norm-bounded \(\mathcal{S}_p(\mathbb{R}^d)\) valued predictable process \(\{G_t\}\).

(b) Given any \(\mathcal{F}_0\) measurable set \(F\), \(\phi \in \mathcal{S}_p(\mathbb{R}^d)\), \(\psi \in \mathcal{S}(\mathbb{R}^d)\) and \(x \in \mathbb{R}^d\) we have
\[
\langle 1_F \tau_X \phi, \psi \rangle = 1_F \langle \tau_X \phi, \psi \rangle = 1_F \langle \phi, \tau_X \psi \rangle
\]
\[
= \langle 1_F \phi, \tau_X \psi \rangle = \langle \tau_X (1_F \phi), \psi \rangle
\]
(3.6)
and hence \(1_F \tau_X \phi = \tau_X (1_F \phi)\). Similarly \(1_F \tau_X \phi = \tau_X (1_F \phi)\).
Using Proposition 3.1 and equations (3.5), (3.6), we can establish Theorem 3.2 when $X$ is bounded and $\xi$ is an $\mathcal{S}_p(\mathbb{R}^d)$ valued simple $\mathcal{F}_0$ measurable function. When $\xi$ is square integrable, the result can be proved by approximating $\xi$ using $\mathcal{S}_p(\mathbb{R}^d)$ valued simple $\mathcal{F}_0$ measurable functions. Finally, via localization under stopping times, we can prove the result for unbounded $X$. \hfill \Box

We need an existence and uniqueness of solution to the following equation:

\begin{equation}
\label{eq:3.7}
dZ_t = \bar{\sigma}(Z_t; \xi). dB_t + \bar{b}(Z_t; \xi) \, dt; \quad Z_0 = \zeta,
\end{equation}

where $\xi$ is an $\mathcal{S}_p(\mathbb{R}^d)$ valued $\mathcal{F}_0$ measurable random variable and $\zeta$ is an $\mathbb{R}^d$ valued $\mathcal{F}_0$ measurable random variable. Unless stated otherwise, we assume that both $\xi, \zeta$ are independent of the Brownian motion $\{B_t\}$. Let $(G_t)$ denote the filtration generated by $\xi, \zeta$ and $\{B_t\}$. Let $G_\infty$ denote the smallest sub-$\sigma$-field of $\mathcal{F}$ containing $G_t$ for all $t \geq 0$. Let $G^p_{\infty}$ be the $P$-completion of $G_\infty$ and let $N^p$ be the collection of all $P$-null sets in $G^p_{\infty}$.

Define

$$
\mathcal{F}^{\xi, \zeta}_t := \bigcap_{s \geq t} \sigma(\mathcal{G}_s \cup N^p), \ t \geq 0
$$

where $\sigma(\mathcal{G}_s \cup N^p)$ denotes the smallest $\sigma$-field generated by the collection $\mathcal{G}_s \cup N^p$. This filtration satisfies the usual conditions. $\mathcal{F}^{\xi, \zeta}_t$ will denote the $\sigma$-field generated by the collection $\bigcup_{t \geq 0} \mathcal{F}^{\xi, \zeta}_t$. If $\zeta$ is a constant, then we write $(\mathcal{F}^\zeta_t)$ instead of $(\mathcal{F}^{\xi, \zeta}_t)$.

**Proposition 3.3.** Suppose the following conditions are satisfied.

(i) $\xi$ is norm-bounded in $\mathcal{S}_p(\mathbb{R}^d)$, i.e. there exists a constant $K > 0$ such that $\|\xi\|_p \leq K$.

(ii) $\mathbb{E}|\xi|^2 < \infty$.

(iii) (Globally Lipschitz in $x$, locally in $y$) For any fixed $y \in \mathcal{S}_p(\mathbb{R}^d)$, the functions $x \mapsto \bar{\sigma}(x; y)$ and $x \mapsto \bar{b}(x; y)$ are globally Lipschitz functions in $x$ and the Lipschitz coefficient is independent of $y$ when $y$ varies over any bounded set $G$ in $\mathcal{S}_p(\mathbb{R}^d)$; i.e. for any bounded set $G$ in $\mathcal{S}_p(\mathbb{R}^d)$ there exists a constant $C(G) > 0$ such that for all $x_1, x_2 \in \mathbb{R}^d, y \in G$,

$$
|\bar{\sigma}(x_1; y) - \bar{\sigma}(x_2; y)| + |\bar{b}(x_1; y) - \bar{b}(x_2; y)| \leq C(G)|x_1 - x_2|.
$$

Then equation \ref{eq:3.7} has a continuous $(\mathcal{F}^{\xi, \zeta}_t)$ adapted strong solution $\{X_t\}$ with the property that $\mathbb{E}\int_0^T |X_t|^2 \, dt < \infty$ for any $T > 0$. Pathwise uniqueness of solutions also holds, i.e. if $\{X^1_t\}$ is another solution, then $P(X_t = X^1_t, t \geq 0) = 1$.

**Proof.** We follow the proof in \cite{19} Theorem 5.2.1 with appropriate modifications. First we show the uniqueness of the strong solution.

Let $\{Z^1_t\}$ and $\{Z^2_t\}$ be two strong solutions of \ref{eq:3.7}. Define two processes $a(t, \omega) := \bar{\sigma}(Z^1_t(\omega); \xi(\omega)) - \bar{\sigma}(Z^2_t(\omega); \xi(\omega))$ and $\gamma(t, \omega) := \bar{b}(Z^1_t(\omega); \xi(\omega)) - \bar{b}(Z^2_t(\omega); \xi(\omega))$. Since $\xi$ is norm-bounded, then by our hypothesis

$$
|a(t, \omega)|^2 \leq C^2 |Z^1_t(\omega) - Z^2_t(\omega)|^2, \ |\gamma(t, \omega)|^2 \leq C^2 |Z^1_t(\omega) - Z^2_t(\omega)|^2
$$

with $C = C(\text{Range}(\xi))$. Using Itô isometry and Cauchy-Schwarz Inequality, we get

\begin{equation}
\label{eq:3.8}
\mathbb{E}|Z^1_t - Z^2_t|^2 \leq 2 \mathbb{E}\int_0^t |a(s)|^2 \, ds + 2t \mathbb{E}\int_0^t |\gamma(s)|^2 \, ds
\end{equation}

\begin{align*}
&\quad \leq 2C^2(1 + t) \int_0^t \mathbb{E}|Z^1_s - Z^2_s|^2 \, ds
\end{align*}
By Gronwall’s inequality, \( E|Z_t^1 - Z_t^2|^2 = 0, \forall t \ge 0 \). This proves the uniqueness.

For the existence of solution we use a Picard type iteration. Set \( Z_t^{(0)} = \zeta \) and then successively define

\[
Z_t^{(k+1)} := \zeta + \int_0^t \tilde{\sigma}(Z_s^k) \, dB_s + \int_0^t \tilde{b}(Z_s^k) \, ds, \forall k \ge 0.
\]

Fix any compact time interval \([0, N]\). For \( k \ge 1, t \in [0, N] \) we have

\[
E|Z_t^{(k+1)} - Z_t^{(k)}|^2 \le 2C^2(1 + N) \int_0^t E|Z_s^k - Z_s^{(k-1)}|^2 \, ds.
\]

Using the Lipschitz continuity for any \( x \in \mathbb{R}^d, y \in \text{Range}(\xi) \) we have, \( |\tilde{\sigma}(x; y) - \tilde{\sigma}(0; y)| + |\tilde{b}(x; y) - \tilde{b}(0; y)| \le C|x| \). But \( |\tilde{\sigma}(0; y)| = ||\sigma||_p \le ||\sigma||_p ||y||_p \) and \( |\tilde{b}(0; y)| = ||b||_p \le ||b||_p ||y||_p \). This shows \( \tilde{\sigma}, \tilde{b} \) has linear growth in \( x \), i.e. there exists a constant \( D = D(G) > 0 \) such that \( |\tilde{\sigma}(x; y)| \le D(1 + |x|), |\tilde{b}(x; y)| \le D(1 + |x|) \) for \( x \in \mathbb{R}^d, y \in \text{Range}(\xi) \). Since \( Z_t^{(0)} = \zeta \) using (3.10) we get

\[
E|Z_t^{(1)} - Z_t^{(0)}|^2 \le 2E \int_0^t |\tilde{\sigma}(\zeta; \xi)|^2 \, ds + 2t E \int_0^t |\tilde{b}(\zeta; \xi)|^2 \, ds
\]

\[
\le 4D^2(1 + N)(1 + E|\zeta|^2)t, \forall t \in [0, N].
\]

Now we use an induction on \( k \) with (3.10) as the recurrence relations and (3.11) as our base step. Then there exists a constant \( R > 0 \) such that

\[
E|Z_t^{(k+1)} - Z_t^{(k)}|^2 \le \frac{(Rt)^{k+1}}{(k+1)!}, \forall k \ge 0, t \in [0, N].
\]

Let \( \lambda \) denote the Lebesgue measure on \([0, N]\). We are going to show that the iteration converges in \( L^2(\lambda \times P) \) and the limit satisfy (3.7). As in [19, Theorem 5.2.1] we can show

\[
\|Z^{(m)} - Z^{(n)}\|_{L^2(\lambda \times P)} = \sum_{k=n}^{m-1} \frac{(RN)^{k+2}}{(k+2)!} \]

where \( m, n \) are positive integers with \( m > n \). Observe that \( \|Z^{(m)} - Z^{(n)}\|_{L^2(\lambda \times P)} \to 0 \) as \( m, n \to \infty \). Using completeness of \( L^2(\lambda \times P) \) we have a limit, which we denote by \( \{ X_t \}_{t \in [0, N]} \). Using (3.12), we also have \( \lim_{n \to \infty} Z_t^{(n)} \overset{L^2(P)}{=} X_t \) for each \( t \in [0, N] \). This \( \{ X_t \} \) is measurable and \( (\mathcal{F}_t^{x, \zeta}) \) adapted. Now using the linear growth of \( x \mapsto \tilde{\sigma}(x; y) \) (for every fixed \( y \in \mathcal{S}_p(R^d) \)) we have

\[
E \int_0^N |\tilde{\sigma}(X_s; \xi)|^2 \, ds \le D^2 E \int_0^N (1 + |X_s|^2)^2 \, ds
\]

\[
\le 2D^2 E \int_0^N (1 + |X_s|^2) \, ds = 2D^2 N + 2D^2 \|X\|_{L^2(\lambda \times P)}^2 < \infty.
\]

For Brownian motion, we can define stochastic integrals for adapted integrands satisfying the above integrability condition (see [17, Chapter 3, Remark 2.11]). Hence \( \{ \int_0^t \tilde{\sigma}(X_s; \xi) \, dB_s \}_{t \in [0, N]} \) exists. Since \( E\int_0^N |X_s|^2 \, ds < \infty \), we have \( \int_0^N |X_s|^2 \, ds < \infty \) almost surely. Using the linear growth of \( x \mapsto \tilde{b}(x; y) \) (for every fixed \( y \in \mathcal{S}_p(R^d) \))
and Cauchy-Schwarz inequality, the existence of the process \( \{ \int_0^t \tilde{b}(X_s; \xi) \, d\xi \}_{t \in [0, N]} \)
can be established. Using Itô isometry and Lipschitz continuity of \( \tilde{\sigma} \) we get
\[
\mathbb{E} \left| \int_0^t \tilde{\sigma}(Z_s^{(k)}; \xi) \, dB_s - \int_0^t \tilde{\sigma}(X_s; \xi) \, dB_s \right|^2 \leq C^2 \mathbb{E} \int_0^N |Z_s^{(k)} - X_s|^2 \, ds.
\]
Using Jensen’s inequality and the Lipschitz property of \( \tilde{b} \) we get
\[
\mathbb{E} \left| \int_0^t \tilde{b}(Z_s^{(k)}; \xi) \, ds - \int_0^t \tilde{b}(X_s; \xi) \, ds \right|^2 \leq C^2 N \mathbb{E} \int_0^N |Z_s^{(k)} - X_s|^2 \, ds.
\]
Using above estimates, for each \( t \in [0, N] \) we have
\[
\int_0^t \tilde{\sigma}(Z_s^{(k)}; \xi) \, dB_s \overset{\mathcal{L}^2(P)}{\underset{k \to \infty}{\longrightarrow}} \int_0^t \tilde{\sigma}(X_s; \xi) \, dB_s,
\]
and
\[
\int_0^t \tilde{b}(Z_s^{(k)}; \xi) \, dB_s \overset{\mathcal{L}^2(P)}{\underset{k \to \infty}{\longrightarrow}} \int_0^t \tilde{b}(X_s; \xi) \, dB_s.
\]
From (3.9) we conclude that for each \( t \in [0, N] \), a.s.
\[
X_t = \zeta + \int_0^t \tilde{\sigma}(X_s; \xi) \, dB_s + \int_0^t \tilde{b}(X_s; \xi) \, ds.
\]
The integral \( \int_0^t \tilde{\sigma}(X_s; \xi) \, dB_s \) has a continuous version (see [19, Theorem 3.2.5]).
We denote the continuous version of \( \{ \zeta + \int_0^t \tilde{\sigma}(X_s; \xi) \, dB_s + \int_0^t \tilde{b}(X_s; \xi) \, ds \}_{t \in [0, N]} \) by \( \{ \tilde{X}_t \}_{t \in [0, N]} \). Then for each \( t \in [0, N] \), a.s.
\[
\tilde{X}_t = \zeta + \int_0^t \tilde{\sigma}(\tilde{X}_s; \xi) \, dB_s + \int_0^t \tilde{b}(\tilde{X}_s; \xi) \, ds = X_t, \text{ a.s.}
\]
In particular, for all \( t \in [0, N] \) we have \( \mathbb{E}|X_t - \tilde{X}_t|^2 = 0 \). Then using the Lipschitz property of \( \tilde{\sigma} \), \( \int_0^t \tilde{\sigma}(X_s; \xi) \, dB_s = \int_0^t \tilde{\sigma}(\tilde{X}_s; \xi) \, dB_s \) a.s. We can also show \( \int_0^t \tilde{b}(X_s; \xi) \, dB_s = \int_0^t \tilde{b}(\tilde{X}_s; \xi) \, dB_s \) a.s. for each \( t \in [0, N] \). Then for each \( t \in [0, N] \), a.s.
\[
\tilde{X}_t = \zeta + \int_0^t \tilde{\sigma}(\tilde{X}_s; \xi) \, dB_s + \int_0^t \tilde{b}(\tilde{X}_s; \xi) \, ds, \text{ a.s.}
\]
Since \( \{ \tilde{X}_t \} \) is continuous, we have, a.s.
\[
\tilde{X}_t = \zeta + \int_0^t \tilde{\sigma}(\tilde{X}_s; \xi) \, dB_s + \int_0^t \tilde{b}(\tilde{X}_s; \xi) \, ds, \text{ a.s.}
\]
So we have obtained a continuous \( (\mathcal{F}_t^{\mathcal{C}}) \) adapted solution for time interval \([0, N]\) for any positive integer \( N \). The uniqueness of this continuous solution follows from the proof of uniqueness given at the beginning of this proof.
Let \( \{ X_t^{(N)} \} \) and \( \{ X_t^{(N+1)} \} \) be the solutions up to time \( N \) and \( N + 1 \) respectively. Then \( \{ X_t^{(N+1)} \} \) is also a continuous solution up to time \( N \) and hence by the uniqueness, is indistinguishable from \( \{ X_t^{(N)} \} \) on \([0, N]\). Using this consistency, we can patch up the solutions \( \{ X_t^{(N)} \} \) to obtain the solution of (3.7) on the time interval \([0, \infty)\).

We now come to a main result regarding the existence and uniqueness of solutions of (3.7).
Theorem 3.4. Suppose the following are satisfied.

(i) $\mathbb{E}[|\xi|^2] < \infty$.
(ii) $\xi = c$, where $c$ is some element in $\mathbb{R}^d$.
(iii) (Globally Lipschitz in $x$, locally in $y$) For any fixed $y \in S_p(\mathbb{R}^d)$, the functions $x \mapsto \bar{\sigma}(x; y)$ and $x \mapsto \bar{b}(x; y)$ are globally Lipschitz functions in $x$ and the Lipschitz coefficient is independent of $y$ when $y$ varies over any bounded set $G$ in $S_p(\mathbb{R}^d)$; i.e. for any bounded set $G$ in $S_p(\mathbb{R}^d)$ there exists a constant $C(G) > 0$ such that for all $x_1, x_2 \in \mathbb{R}^d, y \in G$

$$\left| \bar{\sigma}(x_1; y) - \bar{\sigma}(x_2; y) \right| + \left| \bar{b}(x_1; y) - \bar{b}(x_2; y) \right| \leq C(G) |x_1 - x_2|.$$

Then equation (3.7) has a continuous ($\mathcal{F}_t^\xi$) adapted strong solution $\{X_t\}$ such that there exists a localizing sequence of stopping times $\{\eta_n\}$ with $\mathbb{E} \int_0^{T \wedge \eta_n} |X_t|^2 \, dt < \infty$ for any $T > 0$. Pathwise uniqueness of solutions also holds, i.e. if $\{\tilde{X}_t\}$ is another solution, then $P(X_t = \tilde{X}_t, t \geq 0) = 1$.

Remark 3.5. Theorem 3.4 is also true if $\zeta$ is an $\mathbb{R}^d$ valued $\mathcal{F}_0$ measurable square integrable random variable, which is also independent of the Brownian motion $\{B_t\}$. However, we only need the version for $\zeta = 0$ (see Theorem 3.12).

Proof of Theorem 3.4. For all positive integers $k$, define $\xi^{(k)} := \xi 1_{(\|\xi\|_p \leq k)}$. Note that $\xi^{(k)} \xrightarrow{k \to \infty} \xi$ and the convergence is also almost sure. Also, $1_{(\|\xi\|_p \leq k)} \xi^{(k+1)} = \xi^{(k)}$. By (3.16), we have for any $x \in \mathbb{R}^d, y \in S_p(\mathbb{R}^d), F \in \mathcal{F}$

$$\begin{align*}
1_F \bar{\sigma}(x; y) = \bar{\sigma}(x; 1_F y) = \bar{\sigma}(1_F x; 1_F y) \\
1_F \bar{b}(x; y) = \bar{b}(x; 1_F y) = \bar{b}(1_F x; 1_F y)
\end{align*}$$

By Proposition 3.3 we have the $(\mathcal{F}_t^{\xi^{(k)}})$ adapted (and hence $(\mathcal{F}_t^\xi)$ adapted) strong solution denoted by $\{Z_t^{(k)}\}$, satisfying a.s.

$$Z_t^{(k)} = c + \int_0^t \bar{\sigma}(Z_{s}^{(k)}; \xi^{(k)}) \, dB_s + \int_0^t \bar{b}(Z_{s}^{(k)}; \xi^{(k)}) \, ds, \ t \geq 0.$$ 

Using (3.5) and (3.13), we have a.s. for all $t \geq 0$

$$1_{(\|\xi\|_p \leq k)} Z_t^{(k)} = 1_{(\|\xi\|_p \leq k)} c + \int_0^t \bar{\sigma}(1_{(\|\xi\|_p \leq k)} Z_{s}^{(k)}; \xi^{(k)}) \, dB_s + \int_0^t \bar{b}(1_{(\|\xi\|_p \leq k)} Z_{s}^{(k)}; \xi^{(k)}) \, ds.$$

and

$$1_{(\|\xi\|_p \leq k)} Z_t^{(k+1)} = 1_{(\|\xi\|_p \leq k)} c + \int_0^t \bar{\sigma}(1_{(\|\xi\|_p \leq k)} Z_{s}^{(k+1)}; 1_{(\|\xi\|_p \leq k)} \xi^{(k+1)}) \, dB_s + \int_0^t \bar{b}(1_{(\|\xi\|_p \leq k)} Z_{s}^{(k+1)}; 1_{(\|\xi\|_p \leq k)} \xi^{(k+1)}) \, ds.$$

Equality (4.14) for $k = 0$ completes the proof.

STATIONARY SOLUTIONS 9
Using the uniqueness obtained in Proposition 3.3 (applied to \( F_t^c \) adapted processes), we have a.s.

\[
I_{\{\|\xi\|_p \leq k\}} Z_t^{(k+1)} = I_{\{\|\xi\|_p \leq k\}} Z_t^{(k)}, \quad t \geq 0
\]

with the null set possibly depending on \( k \). Let \( \tilde{\Omega}_k \) be the set of probability 1 where the above relation holds. Then on \( \Omega' := \bigcap_{k=1}^{\infty} \tilde{\Omega}_k \), which is a set of probability 1, \( \Omega' \) holds for all \( k \). Note that \( \{\|\xi\|_p < \infty\} = \Omega \) and hence for any \( \omega \in \Omega \), there exists a positive integer \( k \) such that \( \|\xi(\omega)\|_p \leq k \). Then we can write \( \Omega' = \bigcup_{k=1}^{\infty} (\Omega' \cap (\|\xi\|_p \leq k)) \). Now \( \Omega' \) is an element of \( \mathcal{F} \) with probability 1 and hence \( (\Omega')^c \) is a null set in \( \mathcal{F} \). Since \( (\mathcal{F}_t) \) satisfies the usual conditions, we have \( (\Omega')^c \in \mathcal{F}_0 \) and hence \( \Omega' \in \mathcal{F}_0 \).

We define a process \( \{X_t\} \) as follows: for any \( t \geq 0 \)

\[
X_t(\omega) := \begin{cases} 
Z_t^{(k)}(\omega), & \text{if } \omega \in \Omega' \cap (\|\xi\|_p \leq k), \quad k = 1, 2, \ldots \\
0, & \text{if } \omega \in (\Omega')^c
\end{cases}
\]

From equation (3.14), \( Z_t^{(k+1)} = Z_t^{(k)}, \quad \forall t \geq 0 \) on \( \Omega' \cap (\|\xi\|_p \leq k) \) and hence \( \{X_t\} \) is well-defined. Furthermore \( \{X_t\} \) is \( (\mathcal{F}_t^c) \) adapted and has continuous paths. We now show that \( \{X_t\} \) solves equation (3.7). On \( \Omega' \) we have

\[
I_{\{\|\xi\|_p \leq k\}} X_t = I_{\{\|\xi\|_p \leq k\}} Z_t^{(k)}, \quad \forall t \geq 0, \quad k = 1, 2, \ldots
\]

i.e. above relation holds almost surely. Then for each \( k = 1, 2, \ldots \), a.s. \( t \geq 0 \)

\[
I_{\{\|\xi\|_p \leq k\}} X_t = I_{\{\|\xi\|_p \leq k\}} Z_t^{(k)} \\
= I_{\{\|\xi\|_p \leq k\}} c + \int_0^t \bar{\sigma}(I_{\{\|\xi\|_p \leq k\}} Z_s^{(k)}; \xi^{(k)}).dB_s \\
+ \int_0^t \bar{b}(I_{\{\|\xi\|_p \leq k\}} Z_s^{(k)}; \xi^{(k)})\,ds \\
= I_{\{\|\xi\|_p \leq k\}} c + \int_0^t \bar{\sigma}(I_{\{\|\xi\|_p \leq k\}} X_s; \xi^{(k)}).dB_s \\
+ \int_0^t \bar{b}(I_{\{\|\xi\|_p \leq k\}} X_s; \xi^{(k)})\,ds, \quad (\text{using (3.15)}) \\
= I_{\{\|\xi\|_p \leq k\}} c + \int_0^t I_{\{\|\xi\|_p \leq k\}} \bar{\sigma}(X_s; \xi).dB_s \\
+ \int_0^t I_{\{\|\xi\|_p \leq k\}} \bar{b}(X_s; \xi)\,ds, \quad (\text{using (3.13)}) \\
= I_{\{\|\xi\|_p \leq k\}} c + I_{\{\|\xi\|_p \leq k\}} \int_0^t \bar{\sigma}(X_s; \xi).dB_s \\
+ I_{\{\|\xi\|_p \leq k\}} \int_0^t \bar{b}(X_s; \xi)\,ds, \quad (\text{using (3.13)})
\]

Let \( \bar{\Omega}_k \) denote the set of probability 1 where the above relation holds. Then \( \bar{\Omega} := \bigcap_{k=1}^{\infty} \bar{\Omega}_k \) is also a set of probability 1 and on \( \bar{\Omega} \), for all \( k = 1, 2, \ldots \) and for all \( t \geq 0 \)

\[
I_{\{\|\xi\|_p \leq k\}} X_t = I_{\{\|\xi\|_p \leq k\}} \left( c + \int_0^t \bar{\sigma}(X_s; \xi).dB_s + \int_0^t \bar{b}(X_s; \xi)\,ds \right).
\]
Then on $\tilde{\Omega} \cap (\|\xi\|_p \leq k)$ we have for all $t \geq 0$
\[ X_t = c + \int_0^t \tilde{\sigma}(X_s;\xi).\,dB_s + \int_0^t \tilde{b}(X_s;\xi)\,ds. \]

But $\tilde{\Omega} \cap (\|\xi\|_p \leq k) \uparrow \tilde{\Omega}$ and hence on $\tilde{\Omega}$ above relation holds for all $t \geq 0$. So $\{X_t\}$ is a solution of (3.7).

Taking $\eta_n := \inf\{t \geq 0 : |X_t| \geq n\}$ it follows that $\mathbb{E}\int_0^{\eta_n} |X_s|^2\,dt < \infty$ for any $t > 0$.

To prove the uniqueness, let $\{\tilde{X}_t\}$ be a continuous ($F_t^\xi$) adapted strong solution of (3.7). Then a.s. for all $t \geq 0$
\[
\mathbb{1}_{\{\|\xi\|_p \leq k\}} \tilde{X}_t
= \mathbb{1}_{\{\|\xi\|_p \leq k\}} \left( c + \int_0^t \tilde{\sigma}(\tilde{X}_s;\xi).\,dB_s + \int_0^t \tilde{b}(\tilde{X}_s;\xi)\,ds \right)
= \mathbb{1}_{\{\|\xi\|_p \leq k\}} \left( c + \int_0^t \tilde{\sigma}(\mathbb{1}_{\{\|\xi\|_p \leq k\}} \tilde{X}_s;\xi).\,dB_s + \int_0^t \tilde{b}(\mathbb{1}_{\{\|\xi\|_p \leq k\}} \tilde{X}_s;\xi)\,ds \right)
\]

From the uniqueness obtained in Proposition 3.3 and equation (3.15), we now conclude a.s. for all $t \geq 0$, $\mathbb{1}_{\{\|\xi\|_p \leq k\}} \tilde{X}_t = \mathbb{1}_{\{\|\xi\|_p \leq k\}} Z_t^{(k)} = \mathbb{1}_{\{\|\xi\|_p \leq k\}} X_t$. Since $\{|\|\xi\|| \leq k\} \uparrow \Omega$, this proves $P(X_t = \tilde{X}_t, t \geq 0) = 1$.

In Theorem 3.4 we can assume locally Lipschitz nature of the coefficients $\tilde{\sigma}, \tilde{b}$ instead of those being globally Lipschitz. This extension from globally Lipschitz to locally Lipschitz is a well-known technique (see [13] Theorem 18.3 and the discussion in page 340 about explosion, [24] Chapter IX, Exercise 2.10, [13] Theorem 2.3 and 3.1). The one point compactification of $\mathbb{R}^d$ is denoted by $\hat{\mathbb{R}}^d := \mathbb{R}^d \cup \{\infty\}$. We state the next result without proof.

Theorem 3.6. Suppose the following are satisfied.

(i) $\mathbb{E}|\xi|^2 < \infty$.

(ii) $\zeta = 0$.

(iii) (Locally Lipschitz in $x$, locally in $y$) for any fixed $y \in \mathcal{S}_p(\mathbb{R}^d)$ the functions $x \mapsto \tilde{\sigma}(x; y)$ and $x \mapsto \tilde{b}(x; y)$ are locally Lipschitz functions in $x$ and the Lipschitz coefficient is independent of $y$ when $y$ varies over any bounded set $G$ in $\mathcal{S}_p(\mathbb{R}^d)$; i.e. for any bounded set $G$ in $\mathcal{S}_p(\mathbb{R}^d)$ and any positive integer $n$ there exists a constant $C(G, n) > 0$ such that for all $x_1, x_2 \in B(0, n), y \in G$
\[ |\tilde{\sigma}(x_1; y) - \tilde{\sigma}(x_2; y)| + |\tilde{b}(x_1; y) - \tilde{b}(x_2; y)| \leq C(G, n)|x_1 - x_2|, \]
where $B(0, n) = \{x \in \mathbb{R}^d : |x| \leq n\}$.

Then there exists an ($F_t^\xi$) stopping time $\eta$ and an ($F_t^\xi$) adapted $\hat{\mathbb{R}}^d$ valued process $\{X_t\}$ such that

(a) $\{X_t\}$ solves (3.7) upto $\eta$ i.e. a.s.
\[ X_t = \int_0^t \tilde{\sigma}(X_s;\xi).\,dB_s + \int_0^t \tilde{b}(X_s;\xi)\,ds, 0 \leq t < \eta \]
and $X_t = \infty$ for $t \geq \eta$.

(b) $\{X_t\}$ has continuous paths on the interval $[0, \eta)$.

(c) $\eta = \lim \tau_m \theta_m$ where $\{\theta_m\}$ are ($F_t^\xi$) stopping times defined by $\theta_m := \inf\{t \geq 0 : |X_t| \geq m\}$. 
This is also pathwise unique in this sense: if \( \{X_i^t, \eta_i^t\} \) is another solution satisfying (a), (b), (c), then \( P(X_t = X_i^t, 0 \leq t < \eta \wedge \eta_i) = 1 \).

In Proposition 3.8 we show that stronger assumption on \( \xi \) implies a 'local Lipschitz' condition. We use this result to obtain Theorem 3.9 which is a version of Theorem 3.6. Fix \( p > d + \frac{1}{2} \) and \( y \in \mathcal{S}_p(\mathbb{R}^d) \). Note that \( \delta_x \in \mathcal{S}_{-p}(\mathbb{R}^d) \), \( \forall x \in \mathbb{R}^d \) (see [23, Theorem 4.1]). Hence \( x \mapsto \langle \delta_x, y \rangle : \mathbb{R}^d \to \mathbb{R} \) is well-defined. Abusing notation, we denote this function by \( y \). Next result is about the continuity and differentiability of the function \( y \).

**Proposition 3.7.** Let \( p, q \) be as above. Then the first order partial derivatives of function \( y \) exist and the distribution \( y \) is given by the differentiable function \( y \). Furthermore, the first order distributional derivatives of \( y \) are given by the first order partial derivatives of \( y \), which are continuous functions.

**Proof.** The tempered distribution \( y \) can be expressed as \( y \mathcal{S}_p(\mathbb{R}^d) = \sum_{k=0}^{\infty} \sum_{|n|=k} y_n h_n \) for some \( y_n \in \mathbb{R} \). Note that

1. The Hermite functions \( h_n \) are uniformly bounded (see [23]).
2. From \( \|y\|_p^2 = \sum_{k=0}^{\infty} \sum_{|n|=k} (2k + d)2^p y_n^2 \), we get \( |y_n| \leq \|y\|_p \|2^{n} + d\|^{-p} \).
3. By [23] Chapter II, Section 5], the cardinality \( \# \{ n \in \mathbb{Z}^d_+ : |n| = (k+d-1) \} \). Hence \( \# \{ n \in \mathbb{Z}^d_+ : |n| = k \} \leq C'(2k + d)^{d-1} \) for some \( C' > 0 \).

Using these estimates we can show the convergences of \( \sum_{k=0}^{\infty} \sum_{|n|=k} y_n h_n(x) \) and \( \sum_{k=0}^{\infty} \sum_{|n|=k} y_n \partial h_n(x) \) are uniform in \( x \). The required continuity and differentiability follows from properties of uniform convergence.

**Proposition 3.8.** Let \( p > d + \frac{1}{2} \) and \( \sigma \in \mathcal{S}_{-p}(\mathbb{R}^d) \). Then for any bounded set \( G \) in \( \mathcal{S}_{p+\frac{1}{2}}(\mathbb{R}^d) \) and any positive integer \( n \) there exists a constant \( C(G,n) > 0 \) such that for all \( x_1, x_2 \in B(0, n), y \in G \)

\[
|\bar{\sigma}(x_1; y) - \bar{\sigma}(x_2; y)| \leq C(G,n)|x_1 - x_2|,
\]

where \( B(0,n) = \{ x \in \mathbb{R}^d : |x| \leq n \} \).

**Proof.** Let \( x^1 = (x_1^1, \cdots, x_1^d), x^2 = (x_2^1, \cdots, x_2^d) \in B(0, n) \). Then for any \( y \in \mathcal{S}_p(\mathbb{R}^d) \),

\[
|\bar{\sigma}(x_1; y) - \bar{\sigma}(x_2; y)| \leq \|\sigma\|_{-p}\|\tau_{x_1} y - \tau_{x_2} y\|_p.
\]

The target of the subsequent computations is to obtain an estimate of \( \|\tau_{x_1} y - \tau_{x_2} y\|_p \).

Note that the first order distributional derivatives of \( y \) are given by the first order partial derivatives of \( y \), which are continuous functions (see Proposition 3.7). For any \( 1 \leq i \leq d \) and \( t = \lambda_i x^1_i + (1 - \lambda_i) x^2_i \) with \( \lambda_i \in [0,1] \) we can show

\[
|(x^1_1, \cdots, x^1_{i-1}, t, x^2_{i+1}, \cdots, x^2_d)| \leq 2n.
\]

Let \( y \in \mathcal{S}_{p+\frac{1}{2}}(\mathbb{R}^d) \). Then by Lemma 2.1 there exist constants \( C_n > 0, \tilde{C}_n > 0 \) independent of \( i \) such that

\[
\|\tau(x^1_i, \cdots, x^1_{i-1}, t, x^2_{i+1}, \cdots, x^2_d)\|_p = \|\partial_t \tau(x^1_i, \cdots, x^1_{i-1}, t, x^2_{i+1}, \cdots, x^2_d)\|_p \\
\leq C_n \|\tau(x^1_i, \cdots, x^1_{i-1}, t, x^2_{i+1}, \cdots, x^2_d)\|_p + \frac{1}{2} \leq \tilde{C}_n \|y\|_p + \frac{1}{2}
\]

\[\|\tau(x^1_i, \cdots, x^1_{i-1}, t, x^2_{i+1}, \cdots, x^2_d)\|_p \leq \tilde{C}_n \|y\|_p + \frac{1}{2}\]
The following is an equality of continuous functions.

\[ \tau(x_1^{1}, \ldots, x_{d-1}^{1}, x_{d+1}^{2}, \ldots, x_d^{2}) y(t) - \tau(x_1^{1}, \ldots, x_{d-1}^{1}, x_{d+1}^{2}, \ldots, x_d^{2}) y(t) = \int_{x_1^{1}}^{x_1^{1}} \tau(x_1^{1}, \ldots, x_{d-1}^{1}, t, x_{d+1}^{2}, \ldots, x_d^{2}) \, dt \]

In view of (3.17), we have the equality of distributions in \( S_p(\mathbb{R}^d) \)

\[ \tau(x_1^{1}, \ldots, x_{d-1}^{1}, x_{d+1}^{2}, \ldots, x_d^{2}) y - \tau(x_1^{1}, \ldots, x_{d-1}^{1}, x_{d+1}^{2}, \ldots, x_d^{2}) y = \int_{x_1^{1}}^{x_1^{1}} \tau(x_1^{1}, \ldots, x_{d-1}^{1}, t, x_{d+1}^{2}, \ldots, x_d^{2}) \, dt \]

and

\[ \| \tau(x_1^{1}, \ldots, x_{d-1}^{1}, x_{d+1}^{2}, \ldots, x_d^{2}) y - \tau(x_1^{1}, \ldots, x_{d-1}^{1}, x_{d+1}^{2}, \ldots, x_d^{2}) y \|_p \leq \left( \int_{x_1^{1}}^{x_1^{1}} \| \tau(x_1^{1}, \ldots, x_{d-1}^{1}, t, x_{d+1}^{2}, \ldots, x_d^{2}) \|_p \, dt \right) \leq \hat{C}_n \|y\|_{p+\frac{1}{2}} |x_1^{1} - x_1^{2}|. \]

Now

\[ \tau_{x_1} y - \tau_{x_2} y = \tau(x_1^{1}, \ldots, x_{d-1}^{1}, x_d^{2}) y - \tau(x_1^{1}, \ldots, x_{d-1}^{1}, x_d^{2}) y \]

\[ + \tau(x_1^{1}, \ldots, x_{d-1}^{1}, x_d^{2}) y - \tau(x_1^{1}, \ldots, x_{d-1}^{1}, x_d^{2}) y \]

\[ + \cdots \]

\[ + \tau(x_1^{1}, \ldots, x_{d-1}^{1}, x_d^{2}) y - \tau(x_1^{1}, \ldots, x_{d-1}^{1}, x_d^{2}) y \]

and hence \( \| \tau_{x_1} y - \tau_{x_2} y \|_p \leq \hat{C}_n \|y\|_{p+\frac{1}{2}} \sum_{i=1}^{d} |x_i^{1} - x_i^{2}| \leq d \hat{C}_n \|y\|_{p+\frac{1}{2}} |x_1 - x_2| \). Using this estimate in (3.10), we have \( \hat{\sigma}(x; y) - \hat{\sigma}(x; y) \leq d \hat{C}_n \|\hat{\sigma}\|_{-p} \|y\|_{p+\frac{1}{2}} |x_1 - x_2| \).

In particular, if G is a bounded set in \( S_p(\mathbb{R}^d) \), then for any \( y \in G \)

\[ \| \tau_{x_1} y - \tau_{x_2} y \|_p \leq \hat{C}_n \|\hat{\sigma}\|_{-p} \sup_{y \in G} (\|y\|_{p+\frac{1}{2}} |x_1 - x_2|), \]

i.e. the function \( x \mapsto \hat{\sigma}(x; y) \) is locally Lipschitz in \( x \) for any \( y \in G \) and that the Lipschitz constant can be taken uniformly in \( y \in G \).

Using Proposition 3.8, we get the following version of Theorem 3.6.

**Theorem 3.9.** Let \( p > d + \frac{1}{2} \). Suppose the following are satisfied.

1. \( \sigma, b \in S_{-p}(\mathbb{R}^d) \).
2. \( \xi \) is \( S_{p+\frac{1}{2}}(\mathbb{R}^d) \) valued and \( E\|\xi\|^2_{p+\frac{1}{2}} < \infty \).
3. \( \xi = 0 \).

Then there exists an \( (\mathcal{F}_t^\xi) \) stopping time \( \eta \) and an \( (\mathcal{F}_t^\xi) \) adapted \( \hat{\mathbb{R}}^d \) valued process \( \{X_t\} \) such that

(a) \( \{X_t\} \) solves (3.7) upto \( \eta \) i.e. a.s.

\[ X_t = \int_0^t \hat{\sigma}(X_s; \xi) \, dB_s + \int_0^t \hat{b}(X_s; \xi) \, ds, \quad 0 \leq t < \eta \]

and \( X_t = \infty \) for \( t \geq \eta \).

(b) \( \{X_t\} \) has continuous paths on the interval \([0, \eta)\).

(c) \( \eta = \lim_{m \to \infty} \theta_m \) where \( \{\theta_m\} \) are \( (\mathcal{F}_t^\xi) \) stopping times defined by \( \theta_m := \inf \{ t \geq 0 : |X_t| \geq m \} \).
This is also pathwise unique in this sense: if \((X'_t, \eta')\) is another solution satisfying (a), (b), (c), then \(P(X_t = X'_t, 0 \leq t < \eta \land \eta') = 1\).

We are ready to prove the main result of this section. We make two definitions extending \cite[Definition 3.1]{21} and Definition 3.3. Note that \(\xi\) is assumed to be independent of the Brownian motion \(\{B_t\}\) and \(\hat{S}_p(\mathbb{R}^d) = \mathcal{S}_p(\mathbb{R}^d) \cup \{\delta\}\), where \(\delta\) is an isolated point (see Section 1).

**Definition 3.10.** (A) We say \(\{Y_t\}\) is an \(\mathcal{S}_p(\mathbb{R}^d)\) valued strong solution of equation (3.1), if \(\{Y_t\}\) is an \(\mathcal{S}_p(\mathbb{R}^d)\) valued \((\mathcal{F}_t^\xi)\) adapted continuous process such that a.s. the following equality holds in \(\mathcal{S}_{p-1}(\mathbb{R}^d)\),

\[
Y_t = \xi + \int_0^t A(Y_s). dB_s + \int_0^t L(Y_s) \, ds; \, t \geq 0.
\]

(B) By an \(\hat{S}_p(\mathbb{R}^d)\) valued strong local solution of equation (3.1), we mean a pair \((\{Y_t\}, \eta)\) where \(\eta\) is an \((\mathcal{F}_t^\xi)\) stopping time and \(\{Y_t\}\) an \(\hat{S}_p(\mathbb{R}^d)\) valued \((\mathcal{F}_t^\xi)\) adapted continuous process such that

1. for all \(\omega \in \Omega\), the map \(Y(\omega) : [0, \eta(\omega)) \to \mathcal{S}_p(\mathbb{R}^d)\) is continuous and \(Y_t(\omega) = \delta, \, t \geq \eta(\omega)\).
2. a.s. the following equality holds in \(\mathcal{S}_{p-1}(\mathbb{R}^d)\),

\[
Y_t = \xi + \int_0^t A(Y_s). dB_s + \int_0^t L(Y_s) \, ds; \, 0 \leq t < \eta.
\]

**Definition 3.11.** (A) We say strong solutions to equation (3.1) are pathwise unique, if given any two \(\mathcal{S}_p(\mathbb{R}^d)\) valued strong solutions \(\{Y^1_t\}\) and \(\{Y^2_t\}\), we have \(P(Y^1_t = Y^2_t, t \geq 0) = 1\).

(B) We say strong local solutions to equation (3.1) are pathwise unique, if given any two \(\hat{S}_p(\mathbb{R}^d)\) valued strong solutions \((\{Y^1_t\}, \eta^1)\) and \((\{Y^2_t\}, \eta^2)\), we have \(P(Y^1_t = Y^2_t, 0 \leq t < \eta^1 \land \eta^2) = 1\).

Now we prove the existence and uniqueness of solutions to (3.1).

**Theorem 3.12.** Suppose the following conditions are satisfied.

(i) \(\mathbb{E}[|\xi|^2_p] < \infty\).

(ii) (Globally Lipschitz in x, locally in y) For any fixed \(y \in \mathcal{S}_p(\mathbb{R}^d)\), the functions \(x \mapsto \sigma(x; y)\) and \(x \mapsto \bar{b}(x; y)\) are globally Lipschitz functions in \(x\) and the Lipschitz coefficient is independent of \(y\) when \(y\) varies over any bounded set \(G\) in \(\mathcal{S}_p(\mathbb{R}^d)\); i.e. for any bounded set \(G\) in \(\mathcal{S}_p(\mathbb{R}^d)\) there exists a constant \(C(G) > 0\) such that for all \(x_1, x_2 \in \mathbb{R}^d, y \in G\)

\[
|\sigma(x_1; y) - \sigma(x_2; y)| + |\bar{b}(x_1; y) - \bar{b}(x_2; y)| \leq C(G)|x_1 - x_2|.
\]

Then equation (3.1) has an \((\mathcal{F}_t^\xi)\) adapted continuous strong solution. The solutions are pathwise unique.

First we need a characterization of the solution of equation (3.1). This is an extension of \cite[Lemma 3.6]{21} to random initial condition \(\xi\). The arguments are similar and we state the result without proof.

**Lemma 3.13.** Let \(\xi, \bar{\sigma}, \bar{b}\) be as in Theorem 3.12. Let \(\{Y_t\}\) be an \((\mathcal{F}_t^\xi)\) adapted \(\mathcal{S}_p(\mathbb{R}^d)\) valued strong solution of (3.1). Define a process \(\{Z_t\}\) as follows:

\[
Z_t := \int_0^t \langle \bar{\sigma}, Y_s \rangle \, dB_s + \int_0^t \langle b, Y_s \rangle \, ds, \, t \geq 0.
\]
Then a.s. $Y_t = \tau^*_t \xi$ for $t \geq 0$ and consequently $Z$ solves equation (3.7) with $Z_0 = 0$.

Proof of Theorem 3.12: The proof is similar to that of [21, Theorem 3.4]. By Theorem 3.1 we have a solution \{Z_t\} of (3.7) with initial condition $Z_0 = 0$. Then using the Itô formula in Theorem 3.2 we observe that the process \{$\tau^*_t \xi$\} is a solution. To prove the uniqueness, let \{Y^1_t\}, \{Y^2_t\} be two solutions. Then define \{Z^1_t\} and \{Z^2_t\} corresponding to \{Y^1_t\}, \{Y^2_t\} as in Lemma 3.13. The uniqueness part in Theorem 3.4 implies a.s. $Z^1_t = Z^2_t, \forall t \geq 0$ and hence a.s. $Y^1_t = Y^2_t, \forall t \geq 0$. \(\square\)

Since $Y_t = \tau^*_t \xi$ solves (3.1) (notations as in Theorem 3.12), we have $E\|Y_0\|_p^2 = E\|\xi\|_p^2 < \infty$. Now we prove estimates on $Y_t$ using two different techniques.

**Proposition 3.14.** There exists a localizing sequence \{\eta_n\} such that

$$E \sup_{t \geq 0} \|Y^{\eta_n}_t\|^2 \leq C_n E\|Y_0\|^2,$$

where the constant $C_n$ depends only on $n$.

**Proof.** Consider the process \{Z_t\} as in Lemma 3.13. Define a localizing sequence \{\eta_n\} as follows: $\eta_n := \inf \{t \geq 0 : |Z_t| \geq n\}, n \geq 1$. Now using Lemma 2.1(a) there exists a polynomial $Q$ of degree 2(|p| + 1) such that

$$\|Y^{\eta_n}_t\|^p \leq \|\xi\|^p Q(|Z^{\eta_n}_t|) \leq \|\xi\|^p \sup_{|x| \leq n} Q(|x|).$$

Hence $\sup_{t \geq 0} \|Y^{\eta_n}_t\|^p \leq C_n \|\xi\|^2$ with $C_n = (\sup_{|x| \leq n} Q(|x|))^2$. This implies the required estimate. \(\square\)

Following [21, Lemma 1], we get the next estimate.

**Proposition 3.15.** There exists a localizing sequence \{\eta_n\} such that for any positive real number $T$,

$$E \sup_{t \leq T} \|Y^{\eta_n}_t\|^2_{p-1} \leq C. E\|Y_0\|^2_{p-1},$$

where the constant $C$ depends only on $n$ and $T$.

**Proof.** Define three localizing sequences. For any positive integer $n$, consider

$$\tilde{\eta}_n := \inf \{t \geq 0 : \|Y_t - Y_0\|_p \geq n\},$$

and

$$\eta'_n := \inf \{t \geq 0 : \|\sigma, Y_t\| \geq n, \text{ or } \|b, Y_t\| \geq n\},$$

and $\eta_n := \eta_n \land \eta'_n$. Now using Itô formula for $\|\cdot\|_{p-1}$ we obtain a.s. $t \geq 0$

$$\|Y^{\eta_n}_t\|^2_{p-1} = \|Y_0\|^2_{p-1} + \int_0^{t \wedge \eta_n} 2 \sum_{i=1}^d \langle Y^{\eta_n}_s, A_i Y^{\eta_n}_s \rangle_{p-1} dB_s^{(i)}$$

$$+ \int_0^{t \wedge \eta_n} [2 \langle Y^{\eta_n}_s, L Y^{\eta_n}_s \rangle_{p-1} + \sum_{i=1}^d \|A_i Y^{\eta_n}_s\|^2_{p-1}] ds,$$

where $\{\int_0^{t \wedge \eta_n} 2 \sum_{i=1}^d \langle Y^{\eta_n}_s, A_i Y^{\eta_n}_s \rangle_{p-1} dB_s^{(i)}\}$ is a continuous martingale and $B_t^{(i)}$ denotes the $i$-th component of $B_t$. Then using the Monotonicity inequality ([21, Theorem 2.1 and Remark 3.1]) and taking expectation in (3.18)

$$E\|Y^{\eta_n}_t\|^2_{p-1} \leq E\|Y_0\|^2_{p-1} + \gamma \int_0^t E\|Y^{\eta_n}_s\|^2_{p-1} ds$$
where the constant $\gamma$ depends only on $\eta_n$. Then Gronwall’s inequality implies
\begin{equation}
E\|Y_t^{\eta_n}\|_{p-1}^2 \leq e^{\gamma t}E\|Y_0\|_{p-1}^2, \ t \geq 0.
\end{equation}

Let $\{M_t\}$ and $\{V_t\}$ respectively denote the martingale term and the finite variation term on the right hand side of (3.18). Then using the Monotonicity inequality and (3.19), we get
\begin{equation}
E\sup_{t \leq T} V_t \leq \gamma E\sup_{t \leq T} \int_0^t \|Y_s^{\eta_n}\|_{p-1}^2 \, ds = \gamma \int_0^T E\|Y_s^{\eta_n}\|_{p-1}^2 \, ds \leq \bar{C} E\|Y_0\|_{p-1}^2
\end{equation}
for some constant $\bar{C}$ depending only on $\eta_n$ and $T$.

By [1, Theorem 2.5], for each $1 \leq i \leq d$, there exists a bounded operator $T_i : S_{p-1}(\mathbb{R}^d) \to S_{p-1}(\mathbb{R}^d)$ such that
\begin{equation}
|2 \langle Y_t^{\eta_n}, A_t Y_t^{\eta_n} \rangle_{p-1}| = \left| -2 \sum_{j=1}^d \langle \sigma_{ji}, Y_t^{\eta_n} \rangle \langle Y_t^{\eta_n}, \partial_j Y_t^{\eta_n} \rangle_{p-1} \right| = \sum_{j=1}^d \langle \sigma_{ji}, Y_t^{\eta_n} \rangle \langle Y_t^{\eta_n}, T_j Y_t^{\eta_n} \rangle_{p-1} \leq n \sum_{j=1}^d |\langle Y_t^{\eta_n}, T_j Y_t^{\eta_n} \rangle_{p-1}| \leq \beta \|Y_t^{\eta_n}\|_{p-1}^2
\end{equation}
where $\beta = nd \max\{\|T_j\|_{S_{p-1}(\mathbb{R}^d) \to S_{p-1}(\mathbb{R}^d)} \mid 1 \leq j \leq d\}$. Using (3.21), we can obtain (as in [1, Lemma 1])
\begin{equation}
E\sup_{t \leq T} |M_t| \leq \frac{1}{2} E\sup_{t \leq T} \|Y_t^{\eta_n}\|_{p-1}^2 + C E\|Y_0\|_{p-1}^2.
\end{equation}
for some $C > 0$ depending only on $\eta_n$ and $T$. Using (3.18), (3.20) and (3.22) we get the desired estimate. \hfill \square

The counterpart of Theorem 3.12 involving locally Lipschitz coefficients is as follows. This result is an extension of [21, Theorem 3.4].

**Theorem 3.16.** Suppose the following conditions are satisfied.

(i) $E\|\xi\|_p^2 < \infty$.

(ii) (Locally Lipschitz in $x$, locally in $y$) for any fixed $y \in S_p(\mathbb{R}^d)$ the functions $x \mapsto \bar{\sigma}(x; y)$ and $x \mapsto \bar{b}(x; y)$ are locally Lipschitz functions in $x$ and the Lipschitz coefficient is independent of $y$ when $y$ varies over any bounded set $G$ in $S_p(\mathbb{R}^d)$; i.e. for any bounded set $G$ in $S_p(\mathbb{R}^d)$ and any positive integer $n$ there exists a constant $C(G, n) > 0$ such that for all $x_1, x_2 \in B(0, n), y \in G$
\begin{align}
|\bar{\sigma}(x_1; y) - \bar{\sigma}(x_2; y)| + |\bar{b}(x_1; y) - \bar{b}(x_2; y)| & \leq C(G, n)|x_1 - x_2|,
\end{align}
where $B(0, n) = \{x \in \mathbb{R}^d : |x| \leq n\}$.

Then an $(\mathcal{F}_t^X)$ adapted continuous strong local solution of (3.11) exists. The solutions are also pathwise unique.
4. Stationary Solutions

In this section, we investigate existence of stationary solutions of (3.1). Our approach is to use stationary solutions, if any, of the finite dimensional stochastic differential equation (3.7). Assume that

1. \( f : \mathbb{R}^d \to \mathbb{R}^{d \times d}, g : \mathbb{R}^d \to \mathbb{R}^d \) are measurable functions such that the stochastic differential equation

   \[ dZ_t = f(Z_t)dB_t + g(Z_t)dt, \forall t \geq 0 \quad (4.1) \]

   has a stationary solution and we denote the corresponding invariant measure by \( \nu \). Let \( f = (f_{ij}), g = (g_i), 1 \leq i, j \leq d \) be the component functions of \( f, g \).

2. \( \sigma_{ij}, b_i \) (for \( i, j = 1, \cdots, d \)) are tempered distributions given by continuous functions.

Remark 4.1. Typically, \( f, g \) will be locally Lipschitz functions such that explosions do not happen in finite time. This non-explosion is guaranteed by a 'Liapunov' type criteria (see [25, 7.3.14 Corollary]).

Note that there exists a \( p > 0 \) such that \( \sigma_{ij}, b_i \in \mathcal{S}_p(\mathbb{R}^d) \) for all \( i, j \). Fix such a \( p > 0 \). Consider the following subset of \( \mathcal{S}_p(\mathbb{R}^d) \),

\[ C = \{ \psi \in \mathcal{S}_p(\mathbb{R}^d) : \int_{\mathbb{R}^d} \sigma_{ij}(y + x)\psi(y) \, dy = f_{ij}(x), \forall x \in \mathbb{R} \} \]

\[ \int_{\mathbb{R}^d} b_i(y + x)\psi(y) \, dy = g_i(x), \forall x \in \mathbb{R}, i, j = 1, \cdots, d \} \quad (4.2) \]

Note that \( C \) is a convex set. The motivation behind above conditions requires clarification. Firstly, we want to choose a subset \( C \) of \( \mathcal{S}_p(\mathbb{R}^d) \) such that the resultant equation (4.1) is the same for all deterministic initial conditions \( \psi \) as \( \psi \) varies over the set \( C \). This allows us to think of \( \bar{\sigma}(x; \psi) \) and \( \bar{b}(x; \psi) \) as just \( \bar{\sigma}(x) \) and \( \bar{b}(x) \). Secondly, we want \( \bar{\sigma} = f \) and \( \bar{b} = g \) which is a choice that allows us to use the invariant measure \( \nu \) of (4.1). The set \( C \) considered above provides exactly those conditions, which is pointed out in the next result.

Lemma 4.2. Let \( \psi \in C \). Then \( \bar{\sigma}(x; \psi) = f(x) \) and \( \bar{b}(x; \psi) = g(x) \) for all \( x \in \mathbb{R}^d \).

We show the existence of stationary solutions.

Theorem 4.3. Let \( \xi \) be a \( C \)-valued \( \mathcal{F}_0 \) measurable random variable with \( \mathbb{E}\|\xi\|^2_p < \infty \) and independent of \( \{B_t\} \). Then \( Y_t := \tau_{Z_t}\xi \) is a stationary process and solves

\[ dY_t = A(Y_t) \, dB_t + L(Y_t) \, dt; \quad Y_0 = \tau_{Z_0}\xi \quad (4.3) \]

where \( \{Z_t\} \) is the stationary solution of (4.1).

Proof. We give the proof for dimension \( d = 1 \). The case \( d > 1 \) is similar. Using Lemma 1.2 and the Itô formula in Theorem 3.2 we can show that \( Y_t = \tau_{Z_t}\xi \) solves (4.3).

Let \( \xi \) denote equality in law. Since \( \{Z_t\} \) is a stationary solution to (4.1), for time points \( s, t_1, t_2, \cdots, t_n \geq 0 \) we have

\[(Z_{t_1}, Z_{t_2}, \cdots, Z_{t_n}) \overset{\xi}{=} (Z_{s+t_1}, Z_{s+t_2}, \cdots, Z_{s+t_n}).\]
Let $\psi \in \mathcal{C}$. Then $x \mapsto \tau_x \psi$ is continuous and hence measurable (see [23] proof of Proposition 3.1). Using this fact and the stationarity of $\{Z_i\}$, for Borel sets $G_1, \ldots, G_n$ in $\mathcal{S}_p$, we have

\begin{equation}
\begin{aligned}
P((\tau_{Z_1} \psi, \tau_{Z_2} \psi, \ldots, \tau_{Z_n} \psi) \in G_1 \times G_2 \times \cdots \times G_n) \\
= P((\tau_{Z_{i+1}} \psi, \tau_{Z_{i+2}} \psi, \ldots, \tau_{Z_{2n}} \psi) \in G_1 \times G_2 \times \cdots \times G_n)
\end{aligned}
\end{equation}

Let $\mu_\xi$ denote the law of $\xi$ on $\mathcal{S}_p$. Then using conditional probability and the independence of $\{Z_i\}$ and $\xi$, we have

\begin{align*}
P((\tau_{Z_1} \xi, \tau_{Z_2} \xi, \ldots, \tau_{Z_n} \xi) \in G_1 \times G_2 \times \cdots \times G_n) \\
= \int_{\mathcal{S}_p} P((\tau_{Z_1} \xi, \tau_{Z_2} \xi, \ldots, \tau_{Z_n} \xi) \in G_1 \times G_2 \times \cdots \times G_n | \xi = \psi) \mu_\xi(d\psi) \\
= \int_{\mathcal{C}} P((\tau_{Z_1} \psi, \tau_{Z_2} \psi, \ldots, \tau_{Z_n} \psi) \in G_1 \times G_2 \times \cdots \times G_n) \mu_\xi(d\psi)
\end{align*}

Similarly,

\begin{align*}
P((\tau_{Z_{i+1}} \xi, \tau_{Z_{i+2}} \xi, \ldots, \tau_{Z_{2n}} \xi) \in G_1 \times G_2 \times \cdots \times G_n) \\
= \int_{\mathcal{C}} P((\tau_{Z_{i+1}} \psi, \tau_{Z_{i+2}} \psi, \ldots, \tau_{Z_{2n}} \psi) \in G_1 \times G_2 \times \cdots \times G_n) \mu_\xi(d\psi).
\end{align*}

Using [44] we have

\begin{equation}
P((\tau_{Z_1} \xi, \tau_{Z_2} \xi, \ldots, \tau_{Z_n} \xi) \in G_1 \times G_2 \times \cdots \times G_n) \\
= P((\tau_{Z_{i+1}} \xi, \tau_{Z_{i+2}} \xi, \ldots, \tau_{Z_{2n}} \xi) \in G_1 \times G_2 \times \cdots \times G_n)
\end{equation}

i.e. $\{Y_i\}$ is stationary.

The next result will be used in Example 4.5.

**Lemma 4.4.** The tempered distribution $x$ given by the function $x \in \mathbb{R} \mapsto x$ belongs to $\mathcal{S}_{-p}$ for any $p > \frac{3}{4}$. The tempered distribution given by the function $b(x) := x^3$, $x \in \mathbb{R}$ belongs to $\mathcal{S}_{-p}$ for any $p > \frac{7}{4}$.

**Proof.** First we show that the tempered distribution 1 given by the constant function 1 belongs to $\mathcal{S}_{-p}$ for any $p > \frac{1}{4}$. The Hermite-Sobolev spaces $\mathcal{S}_p(\mathbb{R}; \mathbb{C})$ can be defined corresponding to the Schwartz space $\mathcal{S}(\mathbb{R}; \mathbb{C})$, where the functions are complex valued. The Fourier transform $\hat{\cdot} : \mathcal{S}(\mathbb{R}; \mathbb{C}) \rightarrow \mathcal{S}(\mathbb{R}; \mathbb{C})$ defined by

$$
\hat{\phi}(x) := \frac{1}{\sqrt{2\pi}} \int_{\mathbb{R}} e^{-ixy} \phi(y) \, dy, \quad \forall \phi \in \mathcal{S}(\mathbb{R}; \mathbb{C})
$$

can be extended to $\hat{\cdot} : \mathcal{S}'(\mathbb{R}; \mathbb{C}) \rightarrow \mathcal{S}(\mathbb{R}; \mathbb{C})$ via duality. Since $\hat{\mu}_n = (-i)^n \mu_n$ (see Appendix A.5, equation (A.27)), this gives an isometry $\hat{\cdot} : \mathcal{S}_p(\mathbb{R}; \mathbb{C}) \rightarrow \mathcal{S}_p(\mathbb{R}; \mathbb{C})$. If $T \in \mathcal{S}'(\mathbb{R}; \mathbb{C})$ is such that $\langle T, \phi \rangle \in \mathbb{R}$, $\forall \phi \in \mathcal{S}(\mathbb{R})$ then we have $\|T\|_{\mathcal{S}_p(\mathbb{R}; \mathbb{C})} = \|T\|_{\mathcal{S}_p(\mathbb{R}; \mathbb{C})} = \|T\|_{\mathcal{S}_p(\mathbb{R}; \mathbb{C})}$. Since $\delta_0 \in \mathcal{S}_{-p}$ for any $p > \frac{1}{4}$ (see [23] Theorem 4.1(a)), we have $1 \in \mathcal{S}_{-p}$ for any $p > \frac{1}{4}$.

The operator $M_x$ was defined in Section 2. Observe that for any $\phi \in \mathcal{S}$ and $p > \frac{1}{4}$,

$$
|\langle x, \phi \rangle| = |\langle 1, M_x \phi \rangle| \leq \|1\|_{-p} \|M_x \phi\|_p \leq \|1\|_{-p} \|M_x\|_{\mathcal{S}_{-p} \rightarrow \mathcal{S}_p} \|\phi\|_{p + \frac{1}{4}}.
$$

This implies $x \in \mathcal{S}_{-p}$ for $p > \frac{3}{4}$. Proof for $b$ is similar. \hfill $\square$
Example 4.5. We present two examples where the stationary solutions of (1.1) can be lifted to stationary solutions of (1.3) via Theorem 4.3.

1. Take $d = 1, f(x) \equiv 1, g(x) = -x, \forall x, \sigma = f, b = g$. It is well-known that (1.1) (the Ornstein-Uhlenbeck diffusion) has a stationary solution with the following initial condition:

$$dZ_t = dB_t - Z_t \, dt; \quad Z_0 \sim N(0, \frac{1}{2}),$$

where $N(0, \frac{1}{2})$ denotes the law of a Gaussian random variable with mean 0 and variance $\frac{1}{2}$ (see 15, Example 6.8). Note that $\sigma \in S_{-p}$ for $p > \frac{3}{2}$ (see Lemma 4.4). Take $p > \frac{3}{2}$. It is easy to check that $C = \{ \psi \in S_p : \int R \psi = 1, \int R t^2 \psi(t) dt = 0 \}$. $C$ is non empty since (centered) Gaussian densities satisfy such conditions.

2. We take $\Omega = \phi([0, \infty), \mathbb{R})$ and use the setup of 25, Chapter VII, Sections 3 and 5. Consider $f(x) \equiv 1, g(x) = -x^3, \forall x \in \mathbb{R}, \sigma = f, b = g$. Then (1.1) has an invariant measure, say $\nu$, given by

$$\nu(B) := c \int_B \exp \left( -\frac{x^4}{4} \right) \, dx$$

for any Borel set $B$ in $\mathbb{R}$, where $c = 2^{\frac{7}{4}} (\Gamma(\frac{1}{4}))^{-1}$ is the normalization constant. Take $p > \frac{7}{2}$ so that $\sigma, b \in S_{-p}$ (see Lemma 4.4). Then

$$C = \{ \psi \in S_p : \int R \psi = 1, \int R t \psi(t) dt = 0, \int R t^2 \psi(t) dt = 0, \int R t^3 \psi(t) dt = 0 \}.$$

$C$ is non-empty since $\psi_1, \psi_2 \in C$ where

$$\psi_1(t) = \exp(-t^2) \left[ \frac{3}{2\sqrt{\pi}} - \frac{1}{\sqrt{\pi}} t^2 \right], \psi_2(t) = \exp \left( -\frac{t^4}{4} \right) \left[ \frac{3}{2\sqrt{2\pi}} - \frac{1}{\sqrt{2\pi}} t^2 \right].$$

We now prove an estimate of a stationary solution $\{Y_t\}$.

Proposition 4.6. Let $\xi, \{Z_t\}, \{Y_t\}$ be as in Theorem 4.3. In addition assume that $\xi$ is norm-bounded and $Z_t$ has moments of orders upto $4(|p| + 1)$. Then

(a) $\mathbb{E}\|Y_0\|^2_p = \mathbb{E}\|\tau_{Z_0}\xi\|^2_p < \infty$.

(b) $\mathbb{E}\sup_{t \leq T} \|Y_t\|^2_p \leq C (\mathbb{E}\|Y_0\|^2_p)^{\frac{1}{2}}$, where $C$ is a positive constant depending only on $f, g$ and $T$.

Proof. For any norm-bounded $C$ valued random variable $\xi$, we have $\mathbb{E}\|\tau_{Z_0}\xi\|^2_p < R E P(|Z_0|)$ where $R > 0$ and $P$ is a polynomial of degree $4(|p| + 1)$ (see Lemma 2.1). Then by our assumption, $\mathbb{E}\|\tau_{Z_0}\xi\|^2_p < \infty$.

Observe that $Y_t = \tau_{Z_t} \xi = \tau_{Z_t - Z_0} \tau_{Z_0} \xi = \tau_{Z_t - Z_0} Y_0$. Using Lemma 2.1(a) we have

$$\|Y_t\|^2_p \leq \|Y_0\|^2_p P_k(|Z_t - Z_0|),$$

where $P_k$ is some real polynomial of degree $k = 2(|p| + 1)$ with non-negative coefficients. We use the following estimate to establish the result.

$$\mathbb{E}\sup_{t \leq T} \|Y_t\|^2_p \leq (\mathbb{E}\|Y_0\|^2_p)^{\frac{1}{2}} (\mathbb{E}\sup_{t \leq T} P_k(|Z_t - Z_0|)^2)^{\frac{1}{2}}$$

Now a.s. $Z_t - Z_0 = \int_0^t f(Z_s) \, dB_s + \int_0^t g(Z_s) \, ds$, $t \geq 0$. Using stationarity of $Z$ and the BDG inequalities (15, Proposition 15.7), we can show $\mathbb{E}\sup_{t \leq T} P_k(|Z_t - Z_0|)^2$ is bounded. In this estimate we use the assumption on the moments of $Z_0$. This completes the proof. □
Remark 4.7. We make a few observations.

1. If the convex set $C$ (as in equation (4.2)) has more than one element, then we can consider probability measures on $C$ which are convex combinations of Dirac measures on $C$. By Theorem 4.3, we have the existence of infinitely many stationary solutions corresponding to each of these probability measures. To rationalize, this may be happening due to $C$ being not translation invariant.

2. The set $C$ may be non-compact. Consider the special case $d = 1, f(x) \equiv 1, g(x) = -x, \sigma = f, b = g$ and take $p$ sufficiently large so that the tempered distribution given by the function $x \mapsto x^2$ is in $S_{-p}$. Then the image of $C$ under this tempered distribution (a continuous linear functional on $S_p$) contains $(0, \infty)$, the variances of centered Gaussian densities. So $C$ is unbounded and non-compact.

Remark 4.8. Existence of invariant measure of finite dimensional diffusions and Markov processes has been studied by many authors (to cite only a few see [2, 5, 10, 11, 18], [25, Chapter VII, Section 5]).

Acknowledgement: The author would like to thank Professor B. Rajeev, Indian Statistical Institute, Bangalore for valuable suggestions during the work.
