KEYWORDS
Oral hygiene, Oral cancer, Head and neck cancer, Tooth brushing, General population, Longitudinal study
Abstract

Background: In previous case-control and cross-sectional studies, less frequent dental visits, infrequent tooth brushing, presence of periodontal disease, and increased number of tooth loss were shown to be associated with increased risk of head and neck cancer. However, studies regarding the association of periodontal disease and parameters of oral health with occurrence of head and neck cancer have been lacking particularly in longitudinal setting. We aimed to investigate the relationship between parameters of oral health and risk of head and neck cancer in a nationwide general population-based cohort.

Methods: We included 150,774 subjects from the Korean National Health Insurance System-Health Screening Cohort for demographics, past history, and laboratory findings. The presence of periodontal disease and parameters of oral health including frequency of tooth brushings, dental visit for any reason, expertised dental cleaning, and number of tooth loss were investigated. Head and neck cancer was defined as International Statistical Classification of Diseases-10 codes of ‘C00-C14’.

Results: During median 11.1 years of follow-up, 1,155 (0.76%) head and neck cancers occurred. Based on multivariable analysis, after adjusting for demographics, alcohol intake, smoking, regular exercise, body mass index, systolic blood pressure, blood and urinary laboratory findings, and parameters of oral health, frequent tooth brushing (more than three times per day) was related to lower risk of head and neck cancer (hazard ratio, HR: 0.78, 95% confidence interval, CI: 0.66–0.93, p=0.005). Increased number of tooth loss was positively associated with occurrence of head and neck cancer (p value for trend test for HR <0.001).

Conclusions: The occurrence of head and neck cancer was decreased with the more frequent tooth brushing (more than three times per day) and increased with the number of tooth loss. In regards of head and neck cancer prevention, improving oral hygiene may have significant contribution.

Background

Primary head and neck cancers, such as malignancies in the oral cavity, larynx, hypopharynx, and oropharynx, are emerging and troublesome diseases worldwide [1]. Although recent advances in medicine have improved survival rates, the prognosis of head and neck cancer remains poor [2].
Therefore, identifying and controlling the risk factors or causative factors of head and neck cancer is important. To date, although risk factors such as human papillomavirus (HPV) infection, smoking, and alcohol intake were demonstrated [3], there is unknown part about information regarding other risk factors or related factors, which need additional research.

Periodontal disease is closely associated with oral hygiene [4]. Moreover, parameters of oral health such as number of tooth loss, frequency of tooth brushings, and expertised dental cleaning are related to oral hygiene [5–7]. In previous study, insufficient oral sanitation can induce temporary bacteremia or systemic inflammation, and this inflammatory process is a well-known mediator of cancer [8, 9]. Moreover, periodontitis, which is more severe form of periodontal disease, cause inflammation of periodontal ligament, alveolar bone, and gingiva, resulting in tooth loss and systemic inflammation [10, 11]. Chronic inflammatory reaction due to insufficient oral hygiene and periodontal disease lead oral bacteria to invade gingival epithelial cells, avoid the immune system of the host, and inhibit apoptosis, resulting in development of malignancy [12–14].

Recently, studies regarding a relation between parameters of oral health and risk of head and neck cancer are evolving. Previous studies reported that poor oral health, loss of multiple teeth, and infrequent tooth brushing are related to the risk of upper aerodigestive tract cancers including in the lips, oral cavity, oropharynx, hypopharynx, larynx, and esophagus [15, 16]. Moreover, other case-control and cross-sectional studies, less frequent dental visits, having periodontal disease, infrequent tooth brushing, and large number of tooth loss were shown to be associated with increased risk of head and neck cancer [17, 18]. Recent one meta-analysis showed that infrequent dental visits was increased in head and neck cancer patients [19]. However, studies about the relationship between parameters of oral health and periodontal disease and occurrence of head and neck cancer are sparse in longitudinal setting.

We hypothesized the better oral hygiene would decrease risk of head and neck cancer in a longitudinal study setting. The present study was assessed in a nationwide general population-based cohort to investigate the relation between parameters of oral health and the occurrence of head and neck cancer.
Methods

Database

The National Health Insurance System (NHIS) includes demographics, kinds of covered health insurance, socioeconomic status, database for treatment and diagnosis modalities, and database of medical care institution and a nationwide-supported health examination. This system consists of health information from random sampling of 50 million Koreans [20]. It is the only one insurance provider, provided by the government of Korean. A total of 97% and 3% of the Korean population are provided by the NHIS and the Medical Aid program, respectively. Biannually, members of the system are advised to perform uniformed health examinations from 2002 years [21]. Subjects from the NHIS-Health Screening Cohort (NHIS-HEALS) were enrolled in the present study [22]. The screening program of oral health in NHIS is provided to subscribers ≥40 years of age. The program consists of self-reported surveys including information regarding dental symptoms, oral hygiene behavior, and dental visits during the last year. Subjects are checked by dentists for status of oral health including the number of tooth loss. If oral health is poor, oral hygiene practice is advised to the participants if necessary [23].

Study population

The present study was evaluated on 2003–2004 data from the cohort and included adult subjects 40–79 years of age. In order to rule out the possibility of hidden malignancy, the study was conducted with datasets from 2003 to 2004, taking into account the washout period of one more years from 2003. Among 514,866 total participants, those who had missing data in oral health status (n=343,037), in health examination (n=8,094), or previous history of any malignancy (n=12,961) were excluded. Finally, the complete case dataset of 150,774 subjects were investigated in present study (Fig. 1).

Study variables and definitions

The definition of comorbidity is described in the Supplementary file (Additional file 1). Presence of periodontal disease was defined as when both International Statistical Classification of Diseases-10 (ICD-10) codes (acute periodontitis (K052), chronic periodontitis (K053), periodontosis (K054), other
periodontal disease (K055), and unspecified periodontal disease (K056)) were claimed two or more times by dentist or when subjects were treated periodontal disease (ICD-10 codes K052-56) by dentist based on previous studies [23-25]. Oral hygiene behaviors (expertised dental cleaning, dental visit for any reason, and the frequency of tooth brushings) were acquired from self-reported survey of oral health examination [23]. Frequency of tooth brushings was categorized (more than three times per day, twice per day, and none or one time per day). Expertised dental cleaning and dental visit for any reason were dichotomized (at least one time per year or never). If the subject received expertised dental cleaning or dental visit once every two years, the subject was classified into never group. The number of tooth loss were checked by dentists for oral health examination [23]. The number of tooth loss was classified regardless of the causes (≥15, 8-14, 1-7, and 0). The index date was indicated as the date on examination for the status of oral health. If two or more examinations for oral health were taken between 2003 and 2004, the most recent examination were used for the analysis. The main study outcome was the occurrence of head and neck cancer, which was defined as the presence of ICD-10 codes at least once in the medical treatment database. The ICD-10 code of head and neck cancer was defined as C00-C14 based on previous studies (C00-C06, oral cavity, oral cancer; C07-C08, salivary gland cancer; C09-C14, tonsil and pharynx cancer) [18, 26]. Subjects with a diagnosis of head and neck cancer before the index date were excluded. Diagnosis using ICD-10 codes has already been validated by comparison with the Korean National Cancer Incidence Database. The overall sensitivity of cancer diagnosis using the ICD-10 codes was 92.8% [27].

Statistical analyses

The Chi-square test and independent t-test were conducted to compare categorical and continuous variables, respectively. To compare demographic data of included subjects with that of excluded subjects, because there is a possibility of false positive in large sample size data from Chi-square test and independent t-test, we investigated standardized difference. If the standardized difference is greater than 0.1 with absolute value, it is considered that there is a difference between included subjects and excluded subjects. The cumulative incidence curves analyses by Gray’s Test were conducted to evaluate the relationship of periodontal disease and parameters of oral health with
incidence of head and neck cancer.

Using regression methods of Fine and Gray for competing risk data (death was a competing event for head and neck cancer) were utilized. Hazard ratios (HR) and 95% confidence intervals (CI) were calculated. Multivariable regression models were performed with adjustment for confounding factors which are age, sex, income level, alcohol intake, smoking, body mass index, regular exercise, hypertension, diabetes mellitus, and dyslipidemia in model 1; variables in model 1 as well as systolic blood pressure, laboratory finding in urine and blood in model 2; variables in model 2 as well as frequency of tooth brushing, periodontal disease, expertised dental cleaning, dental visit for any reason, and number of tooth loss in model 3. To investigate trend for HR of number of tooth brushing and tooth loss, p value for trend was estimated. The sensitivity analyses were performed in subjects without alcohol intaken and non-smokers. The subgroup analysis according to location of head and neck cancer (1. oral cavity or oral cancer; 2. salivary gland cancer; 3. tonsil or pharynx cancer) were investigated by a two-sided Wald test in the regression methods of Fine and Gray for competing risk data. All statistical analyses were performed using SAS software (version 9.2, SAS Institute, Cary, NC, USA). A $p$-value <0.05 was considered statistically significant.

**Results**

When comparing demographics, elderly people, women and subjects with lower income level were more frequently observed in excluded subjects (Table S1). The mean ± standard deviation age of participants was 52.2 ± 8.7 years; 60.9% were males, 39.3% had hypertension, 9.0% had diabetes mellitus, and 25.3% were current smokers. Approximately 13.1% and 24.1% of included subjects had periodontal disease and one or more tooth loss, respectively. Based on self-reported survey, 40.6% of the participants brushed teeth with $\geq 3$ times/day. Approximately 23.8% of subjects had at least once expertised dental cleaning per year (Table 1).

After a median 11.1 years of follow-up, 1,155 head and neck cancers had occurred. The estimated 10-year event rate for head and neck cancer was 0.76%. The cumulative incidence curves for head and neck cancer are presented in Fig. 2 based on frequency of tooth brushing, expertised dental cleaning, dental visit for any reason, and number of tooth loss. The risk of head and neck cancer was lower...
when a subject had better oral hygiene, for example frequent tooth brushing, frequent dental visits, and expertised dental cleaning. In contrast, poor oral health status including a greater number of tooth loss was associated with a higher risk of head and neck cancer.

Based on multivariable regression, frequent tooth brushing (more than three times per day) was significantly associated with lower risk of head and neck cancer (HR: 0.75, 95% CI: 0.64–0.89, p=0.001, p for trend <0.001 in model 1; HR: 0.76, 95% CI: 0.64–0.90, p=0.002, p for trend=0.001 in model 2; HR: 0.79, 95% CI: 0.66–0.94, p=0.007, p for trend=0.005 in model 3) (Table 2). Increased number of tooth loss was positively related to occurrence of head and neck cancer based on multivariable analysis (p <0.001 in model 1, 2, and 3). More than 15 tooth loss was positively associated with risk of head and neck cancer (HR: 1.71, 95% CI: 1.26–2.31, p=0.001 in model 1; HR: 1.68, 95% CI: 1.24–2.28, p<0.001 in model 2; HR: 1.66, 95% CI: 1.22–2.25, p=0.001 in model 3) (Table 2). However, adjusting for confounding factors, the statistical significance of the relation between expertised dental cleaning and dental visit for any reason and future occurrence risk of head and neck cancer was diminished in models 1–3 (Table 2).

In sensitivity analyses, the association of frequent tooth brushing and number of tooth loss with occurrence risk of head and neck cancer was consistently noted in subjects without alcohol intake and non-smokers (Table S2 and S3). In subgroup analysis, the relationship of frequent tooth brushing and number of tooth loss with occurrence risk of head and neck cancer was consistently noted in oral cavity or oral cancer (Table S4). The number of tooth loss (≥15) was associated with future occurrence risk of salivary gland cancer (Table S5). In contrast, periodontal disease and parameters of oral health were not related to occurrence of tonsil or pharynx cancer (Table S6).

**Discussion**

Our findings from the present study are frequent tooth brushing may lower the occurrence of head and neck cancer even after adjusting for important confounding factors. In addition, poor oral health evidenced by a greater number of tooth loss was independently related to future occurrence of head and neck cancer.

In previous studies, infrequent tooth brushing was associated with head and neck malignancies,
particularly in tongue, gum, and other areas of the mouth [6, 28, 29]. Tooth brushing less than once a day was also associated with risk of tongue cancer (odds ratio: 2.1) and cancer in other parts of the mouth (odds ratio: 2.4) [30]. In a case-control study of Chinese subjects, the risk of oral cancer was 6.9-fold greater for males and 2.5-fold for females in subjects who infrequently brushed their teeth [31]. Results in another European study indicated daily brushing was a protective factor against developing oral cancer (odds ratio: 0.41) [32]. The results from the present study are in agreement with the above-mentioned studies and provide additional information for longitudinal relationship of tooth brushing with decreased occurrence of head and neck cancer.

In the present study, a positive association between loss of multiple teeth and the occurrence of head and neck cancer was observed. These association has been consistently reported in previous studies. In a meta-analysis of case-control and cross-sectional studies, the odds ratio for tooth loss more than 5 of head and neck malignancy was 2.0 [33]. In addition, in a dose-response meta-analysis of prospective cohort studies, tooth loss was significantly related to a higher occurrence of head and neck cancer [34]. Tooth loss may be closely related to failure of maintaining oral hygiene (infrequent tooth brushing, dental visits, and expertised dental cleaning), exposure to cancer-inducing factors such as smoking, nitrosamines, or alcohol, and secondary inflammation or infection of the oral cavity [35, 36]. Because these factors may promote malignancy [37, 38], our hypothesis is plausible.

To investigate of which site head and neck cancer is more associated with oral hygiene, we analyzed the site specific risk according to oral disease and hygiene. For the oral cavity cancers, the results were quite similar to the main result of present study. On the other hand, for the tonsil or pharynx cancer, risk of cancer occurrence was not associated with oral health and oral hygiene, statistically significantly. This result seems supportive of the hypothesis that, poor oral hygiene can mediate cancer mainly in oral cavity.

In the present study, visiting the dentist and expertised dental cleaning were associated with decreased occurrence of head and neck cancer. However, infrequent dental visits was related to an increased occurrence of head and neck cancer based on univariable analysis. These results are consistent with previous studies [6, 7, 39, 40]. Conversely, after adjusting for various important
confounding factors, the association between dental visits and expertised dental cleaning and occurrence of malignancy was not statistically significant. These results may be due to other factors, which are more likely associated with malignancy than dental visits and expertised dental cleaning. Paradoxically, the presence of periodontal disease was decreased occurrence of head and neck cancer. Subjects with periodontal disease visit hospitals more often than subjects without periodontal disease and receive more frequent health care. Moreover, in our study, definition of periodontal disease using the ICD-10 code does not apply recently published classification criteria and definitions of case for periodontal disease [41]. In addition, the discrepancy of age, sex, income level between the included subjects and excluded those may explain these results.

The present study had several limitations. First, although this was a longitudinal study and the cohort was retrospectively analyzed without intervention, therefore, the information bias could not be excluded and causal relationships were not confirmative. Second, many subjects were excluded before analysis due to the missing value in the oral health status data. Because the oral examination was not a mandatory test item, this exclusion may lead to a selection bias, leaving the subjects with healthier behavior in the study dataset. Third, although we used a wash-out period of one year before the index date, a hidden malignancy at baseline remains a possibility. Fourth, the frequency of tooth brushings and expertised dental cleanings were assessed based on a self-reported survey, which may be subject to recall bias. Fifth, although parameters of oral health can be altered during follow up, our study did not take into account these time-varying factors. Sixth, although HPV infection and their treatment were important covariates for occurrence of head and neck cancer, because treatment for HPV infections was not covered by national insurance, our health claim data could not adjust the HPV-related parameters. Seventh, the NHIS-HEALS cohort dataset does not supply information about the education or occupations of the subjects. Therefore, income level was the only adjusted variable that reflects socioeconomic status. Finally, because this is a cohort study with a large number of subjects without a sample-size calculation, we cannot completely rule out the possibility that the association between oral health and the occurrence of head and neck cancer is statistically significant only due to the large sample size. Nevertheless, the present study had several strengths. Contrary to previous
studies, which were mostly case-control studies, this was a nationwide, general population-based longitudinal study. In addition, this study included a relatively large sample size. Distinct from previous studies, various risk factors were included such as comorbidities, laboratory findings, alcohol intake, smoking status, and oral hygiene, and adjusted in multivariable analysis in this study.

Conclusions
The better oral hygiene behavior, particularly brushing teeth ≥ 3 times a day, was associated with a reduced risk of head and neck cancer. Poor oral hygiene, especially the greater number of tooth loss, was increased risk of head and neck cancer. Therefore, improving oral hygiene may have significant contribution to lower the risk of head and neck cancer.

Tables

**Table 1.** Baseline characteristics of the study population.

| Characteristics                        | Total |
|----------------------------------------|-------|
| Number of subjects                     | 150,774 |
| Age (years)                            | 52.2 ± 8.7 |
| Male sex                               | 91,855 (60.9) |
| Income levels                          |       |
| Fifth quintile (highest)               | 59,339 (39.4) |
| Fourth quintile                        | 30,701 (20.4) |
| Third quintile                         | 20,871 (13.8) |
| Second quintile                        | 18,962 (12.6) |
| First quintile (lowest)                | 20,665 (13.7) |
| Covered by medical aid                 | 236 (0.2) |
| Alcohol intake                         | 71,800 (47.6) |
| Smoking status                         |       |
| Never smoker                           | 97,037 (64.4) |
| Former smoker                          | 15,590 (10.3) |
| Current smoker                         | 38,147 (25.3) |
| Regular physical activity              | 14,570 (9.7) |
| Anthropometric measurements            |       |
| Body mass index (kg/m^2)               | 23.9 ± 2.9 |
| Systolic blood pressure (mmHg)         | 126.4 ± 17.2 |
| Diastolic blood pressure (mmHg)        | 79.4 ± 11.2 |
| Comorbidities                          |       |
| Hypertension                           | 59,234 (39.3) |
| Diabetes mellitus                      | 13,609 (9.0) |
Dyslipidaemia

Laboratory findings
- Total cholesterol (mg/dL): 198.2 ± 36.4
- Fasting blood sugar (mg/dL): 97.0 ± 29.0
- Aspartate aminotransferase (U/L): 26.0 ± 16.0
- Alanine aminotransferase (U/L): 25.4 ± 19.8
- Gamma glutamyl transferase (U/L): 38.3 ± 53.0
- Proteinuria (≥1+ in dipstick test): 4,495 (3.0)

Oral hygiene care
- Tooth brushing (times/day)
  - 0-1: 22,111 (14.7)
  - 2: 67,502 (44.8)
  - ≥3: 61,161 (40.6)
- Dental visit for any reason: 63,506 (42.1)
- Expertised dental cleaning: 35,859 (23.8)

Oral health status
- Periodontal disease: 19,861 (13.1)
- Number of tooth loss
  - 0: 114,459 (75.9)
  - 1-7: 32,545 (21.6)
  - 8-14: 2,235 (1.5)
  - ≥15: 1,535 (1.0)

Data are expressed as the mean ± SD, or n (%).

Table 2. Risk of head and neck cancer based on periodontal disease and parameters of oral health.

| No. of subjects | No. of events | Follow-up duration (person-years) | Age-adjusted incidence rate (per 1000 person-yrs, 95% CI) | Unadjusted model | Age, sex-adjusted model |
|-----------------|---------------|---------------------------------|----------------------------------------------------------|-----------------|------------------------|
|                 |               |                                 | Age-adjusted incidence rate (per 1000 person-yrs, 95% CI) |                 |                        |
| Periodontal disease |               |                                 |                                                          |                 |                        |
| No              | 130913        | 1036                            | 14991 00                                                  | 0.52 (0.49, 0.56) | 1 (ref)                |
| Yes             | 19861         | 119                             | 22524 7                                                   | 0.39 (0.33, 0.47) | 0.76 (0.63, 0.92)     |

Frequency of tooth

---
| brushing (times/day) | Multivariable model 1 was adjusted for age, sex, income level, alcohol intake, smoking status, regular exercise, body mass index (kg/m²), hypertension, diabetes, and dyslipidemia. | Multivariable model 2 was adjusted for the variables listed above as well as systolic blood pressure, total cholesterol, fasting blood sugar, aspartate aminotransferase, alanine aminotransferase, gamma glutamyl transpeptidase, and proteinuria. | Multivariable model 3 was adjusted for the variables listed above as well as periodontal disease, frequency of tooth brushing, dental visit for any reason, expertised dental cleaning, and number of tooth loss. |

CI, confidence interval; HR, hazard ratio.

*: The trend test for hazard ratios

Multivariable analysis was performed by using regression methods of Fine and Gray for competing risk data (death is a competing event for head and neck cancer).

Figures

![Flowchart of Study Subjects](image)

Figure 1

Flow chart of the study subjects.
Figure 2

The cumulative incidence curves which analyzed by Gray's Test for the association of parameters of oral health with occurrence of head and neck cancer. Cumulative incidence curves show that risk of head and neck cancer depends on the frequency of tooth brushings (A) \((p < 0.001)\), dental visit for any reason (B) \((p = 0.040)\), expertised dental cleaning (C) \((p < 0.001)\), and number of tooth loss (D) \((p < 0.001)\).
