HYDRODYNAMIC LIMIT OF ASYMMETRIC EXCLUSION PROCESSES UNDER DIFFUSIVE SCALING IN \( d \geq 3 \).

C. LANDIM, M. SUED AND G. VALLE

Abstract. We consider the asymmetric exclusion process. We start from a profile which is constant along the drift direction and prove that the density profile, under a diffusive rescaling of time, converges to the solution of a parabolic equation.

1. Introduction

Consider the asymmetric exclusion process evolving on the lattice \( \mathbb{Z}^d \). This dynamics can be informally described as follows: fix a translation invariant transition probability \( p(x, y) = p(0, y - x) = p(y - x) \). Each particle, independently from the others, waits a mean one exponential time, at the end of which being at \( x \) it chooses the site \( x + y \) with probability \( p(y) \). If the chosen site is unoccupied, the particle jumps, otherwise it stays where it is. In both cases, after its attempt, the particle waits a new mean one exponential time.

The configurations of the state space \( \{0, 1\}^{\mathbb{Z}^d} \) are denoted by the Greek letter \( \eta \) so that, for \( x \in \mathbb{Z}^d \), \( \eta(x) \) is equal to 1 or 0, whether site \( x \) is occupied or not. For each density \( 0 \leq \alpha \leq 1 \), the Bernoulli product measure with parameter \( \alpha \), denoted by \( \nu_\alpha \), is invariant.

The macroscopic evolution of the process under Euler rescaling is described \cite{14} by the first order quasilinear hyperbolic equation

\[
\partial_t \rho + q \cdot \nabla F(\rho) = 0,
\]

where \( F(a) = a(1 - a) \) and \( q \in \mathbb{R}^d \) is the mean drift of each particle : \( q = \sum_z \varepsilon p(z) \). Assume that the system starts from a product measure with slowly varying density \( \rho_0(\varepsilon u) \). Under Euler scaling (times of order \( t \varepsilon^{-1} \)) the density has still a slowly varying profile \( \lambda_\varepsilon(t, \varepsilon u) \) which converges weakly (in fact pointwisely at every continuity point, \cite{7}) to the entropy solution of equation (1.1) with initial data \( \rho_0 \).

In the context of asymmetric interacting particle systems the Navier–Stokes equations takes the form

\[
\partial_t \rho + q \cdot \nabla F(\rho) = \varepsilon \sum_{i,j} \partial_{u_i} \left( a_{i,j}(\rho^\varepsilon) \partial_{u_j} \rho^\varepsilon \right),
\]

where \( a \) is a diffusion coefficient. Three different interpretations have been proposed for the Navier–Stokes corrections : 

(a) The incompressible limit \( \cite{3}, \cite{4} \) : Consider a small perturbation of a constant profile \( \alpha_0 : \rho_0^\varepsilon = \alpha_0 + \varepsilon \varphi \). Assuming that this form persists at latter
times \((\rho(t, u) = \alpha_0 + \varepsilon \varphi(t, u))\) we obtain from (1.2) the following equation for \(\varphi_\varepsilon = \varphi(t\varepsilon^{-1}, u)\)

\[
\partial_t \varphi_\varepsilon + \varepsilon^{-1} F'(\alpha_0)q \cdot \varphi_\varepsilon + (1/2) F''(\alpha_0)q \cdot \nabla \varphi_\varepsilon^2 = a_{i,j}(\alpha_0) \sum_{i,j} \partial^2_{u_i,u_j} \varphi_\varepsilon + O(\varepsilon).
\]

A Galilean transformation \(m_\varepsilon(t, u) = \varphi_\varepsilon(t, u + \varepsilon^{-1} t F'(\alpha_0))\) permits to remove the diverging term of the last differential equation and to get a limit equation for \(m = \lim_{\varepsilon \to 0} m_\varepsilon\)

\[
\partial_t m + (1/2) F''(\alpha_0)q \cdot \nabla m^2 = a_{i,j}(\alpha_0) \sum_{i,j} \partial^2_{u_i,u_j} m.
\]

(b) First order correction to the hydrodynamic equation (2, 8) : Fix a smooth profile \(\rho_0: \mathbb{R}^d \to \mathbb{R}_+\) and consider a process starting from a product measure with slowly varying density \(\rho_0(\varepsilon u)\). We have seen that under Euler scaling the density is still a slowly varying profile \(\lambda_\varepsilon(t, \varepsilon u)\) which converges weakly to the entropy solution of equation (1.1) with initial data \(\rho_0\). This second interpretation asserts that the solution of equation (1.2) with initial profile \(\rho_0\) approximates \(\lambda_\varepsilon\) up to the order \(\varepsilon\):

\[
\varepsilon^{-1}(\lambda_\varepsilon - \rho_\varepsilon) \to 0
\]
in a weak sense as \(\varepsilon \downarrow 0\).

(c) Long time behaviour (5, 11) : The third interpretation consists in analyzing the behaviour of the solution of equation (1.2) in time scales of order \(t\varepsilon^{-1}\). Let \(b_\varepsilon(t, u) = \rho(t\varepsilon^{-1}, u)\). From (1.2) we obtain the following equation for \(b_\varepsilon\):

\[
\partial_t b_\varepsilon + \varepsilon^{-1} q \cdot \nabla F(b_\varepsilon) = \sum_{i,j} \partial_{u_i} \left( a_{i,j}(b_\varepsilon) \partial_{u_j} b_\varepsilon \right).
\]

To eliminate the diverging term \(\varepsilon^{-1} q \cdot \nabla F(b_\varepsilon)\), assume that the initial data (and therefore the solution at any fixed time) is constant along the drift direction : \(q \cdot \nabla \rho_0 = 0\). In this case we get the parabolic equation

\[
\partial_t b_\varepsilon = \sum_{i,j} \partial_{u_i} \left( a_{i,j}(b_\varepsilon) \partial_{u_j} b_\varepsilon \right)
\]

which describes the evolution of the system in the hyperplane orthogonal to the drift.

Notice that while the first and the third interpretation concern the behaviour of the system under diffusive rescaling, the second one is a statement on the process under Euler rescaling. Interpretation (a) and (b) have been proved [3], [5] for asymmetric simple exclusion processes in dimensions \(d \geq 3\) and a double variational formula for the diffusion coefficient was deduced. As one would expect, the diffusion coefficients of the two interpretations are the same and may be expressed by a Green–Kubo formula [13]. It was also proved (Corollary 6.2, [2]) that the diffusion coefficient is strictly bounded below in the matrix sense by the diffusion coefficient that governs the evolution of the symmetric process and that it depends smoothly on the density [12].

In contrast with interpretations (a) and (b), the third one is meaningful in dimension \(d \geq 2\). It has been proved in [4] for asymmetric zero range processes. The purpose of this paper is to give a rigorous proof of the third interpretation in the case of asymmetric exclusion processes in dimension \(d \geq 3\). The proof in this
context is much more demanding because the process is nongradient. In particular, we obtain a non-trivial diffusion coefficient.

2. Notation and Results

Fix a finite range probability measure \( p(\cdot) \) on \( \mathbb{Z}^d \). The exclusion process evolving on the discrete torus \( \mathbb{T}_N^d = \{0, \ldots, N-1\}^d \) associated to \( p(\cdot) \) is the Markov process on the state space \( \mathcal{X}_N = \{0,1\}^{\mathbb{T}_N^d} \) whose generator \( L_N \) acts on a local function \( f \) as

\[
(L_N f)(\eta) = \sum_{x,y \in \mathbb{T}_N^d} p(y) \eta(x) \{1 - \eta(x+y)\} [f(\sigma^{x,y} \eta) - f(\eta)],
\]

where \( \sigma^{x,y} \eta \) is the configuration obtained from \( \eta \) by exchanging the occupation variables \( \eta(x), \eta(x+y) \):

\[
(\sigma^{x,y} \eta)(z) = \begin{cases} 
\eta(z) & \text{if } z \neq x, x+y, \\
\eta(x) & \text{if } z = x+y, \\
\eta(x+y) & \text{if } z = x.
\end{cases}
\]

Fix \( \alpha \) in \( (0,1) \) and denote by \( \nu_\alpha^N \) the Bernoulli product measure on \( \mathcal{X}_N \) with density \( \alpha \). Let \( L_N^* \) be the adjoint of \( L_N \) in \( L^2(\nu_\alpha^N) \). This operator is obtained by replacing \( p(y) \) by \( p^*(y) = p(-y) \) in (2.1).

Denote by \( \mathbb{T}^d \) the \( d \)-dimensional torus. Fix a continuous function \( \rho_0 : \mathbb{T}^d \to [0,1] \) and denote by \( \nu_{\rho_0(\cdot)}^N \) the product measure on \( \{0,1\}^{\mathbb{T}_N^d} \) associated to \( \rho_0 \). This is the Bernoulli product measure on \( \{0,1\}^{\mathbb{T}_N^d} \) with marginals given by

\[
\nu_{\rho_0(\cdot)}^N \{ \eta(x) = 1 \} = \rho_0(x/N)
\]

for \( x \) in \( \mathbb{T}_N^d \).

For \( N \geq 1 \) and a configuration \( \eta \), denote by \( \pi^N(\eta) \) the empirical measure associated to \( \eta \). This is the measure on \( \mathbb{T}^d \) obtained by assigning mass \( N^{-d} \) to each particle of \( \eta \):

\[
\pi^N(\eta) = N^{-d} \sum_{x \in \mathbb{T}_N^d} \eta(x) \delta_{x/N},
\]

where \( \delta_u \) stands for the Dirac measure on \( u \). It has been proved in [14] that if particles are initially distributed according to \( \nu_{\rho_0(\cdot)}^N \) for some profile \( \rho_0 : \mathbb{T}^d \to [0,1] \), then \( \pi^N(\eta_{t,N}) \) converges in probability to \( \rho(t, u) du \), where \( \rho \) is the entropy solution of the Burgers equation

\[
\partial_t \rho + q \cdot \nabla F(\rho) = 0,
\]

where \( F(a) = a(1-a) \) and \( q \in \mathbb{R}^d \) is the mean drift of each particle: \( q = \sum_z z p(z) \).

In this article, we investigate the diffusive behavior of the empirical measure \( \pi^N \), that is, its evolution in times of order \( N^2 \).

As time increases, the solution of Burgers equation (1.2) converges to a stationary profile which is constant along the drift direction:

\[
\lim_{t \to \infty} \rho(t, u) = \rho_\infty(u) = \int_0^1 \rho_0(u + rq) \, dr,
\]

provided \( \rho_0 \) stands for the initial data. The limit should be understood pointwisely. In particular, in a time scale of order \( N^2 \), the profile of the empirical measure should immediately become constant along the drift direction.
We shall therefore assume that the initial state is a product measure \( \nu_{\rho_0}(\cdot) \), associated to a profile \( \rho_0 \) constant along the drift direction:

\[
q \cdot \nabla \rho_0(u) = 0 \tag{2.3}
\]

for all \( u \) in \( T^d \). Assume furthermore that the profile is bounded away from 0 and 1:

\[
\delta_0 \leq \rho_0(u) \leq 1 - \delta_0 \tag{2.4}
\]

for some \( \delta_0 > 0 \).

**Theorem 2.1.** Assume that the initial state is distributed according to \( \nu_{\rho_0}(\cdot) \), where the profile \( \rho_0 \) satisfies \(2.3, 2.4\). There exists a smooth matrix-valued function \( a(\alpha) = \{a_{i,j}(\alpha), 1 \leq i, j \leq d\} \) with the following property. For each \( t \geq 0 \), \( \pi_N(\eta_{tN^2}) \) converges in probability to \( \rho(t,u)du \), where the density \( \rho \) is the solution of the parabolic equation

\[
\begin{cases}
\partial_t \rho = \sum_{i,j} \partial_{u_i}(a_{i,j}(\rho)\partial_{u_j} \rho), \\
\rho(0,\cdot) = \rho_0(\cdot).
\end{cases} \tag{2.5}
\]

In this theorem, \( a_{i,j}(\alpha) = D_{i,j}(\alpha) + (1/2)(1 - 2\alpha)\sigma_{i,j} \), where \( D_{i,j}(\alpha) \) is the matrix given by \(5.9\) and \( \sigma_{i,j} \) the covariance matrix of the transition probability \( p(\cdot) \):

\[
\sigma_{i,j} = \sum_{y \in \mathbb{Z}^d} p(y)y_iy_j.
\]

Notice that by the maximum principle, \( \delta_0 \leq \rho(t,u) \leq 1 - \delta_0 \) for all \( (t,u) \). Moreover, the solution of the hydrodynamic equation is constant along the drift direction,

\[
\sum_{i=1}^d q_i(\partial_{u_i}\rho)(t,u) = 0
\]

because so is the initial data.

This theorem is an elementary consequence of the following estimate on the relative entropy of the state of the process with respect to a local Gibbs state. For two measures \( \mu, \nu \) on \( \{0,1\}^{T^d} \), denote by \( H_N(\mu|\nu) \) the relative entropy of \( \mu \) with respect to \( \nu \):

\[
H_N(\mu|\nu) = \sup_f \left\{ \int f \, d\mu - \log \int e^f \, d\nu \right\},
\]

where the supremum is carried over all bounded, continuous functions, which in our finite setting coincide with all functions. For \( t \geq 0 \), denote by \( S^N_t \) the semigroup associated to the Markov process with generator \(2.1\) speeded up by \( N^2 \).

**Theorem 2.2.** Under the assumptions of Theorem 2.1 on the initial profile \( \rho_0 \), let \( \{\mu_N, N \geq 1\} \) be a sequence of probability measures on \( \{0,1\}^{T^d} \) whose entropy with respect to \( \nu_{\rho_0}(\cdot) \) is of order \( o(N^d) \):

\[
H_N(\mu_N|\nu_{\rho_0}(\cdot)) = o(N^d).
\]

Then, for every \( t \geq 0 \), the relative entropy of the state of the process at time \( tN^2 \) with respect to \( \nu_{\rho(t,\cdot)}(\cdot) \) is also of order \( o(N^d) \):

\[
H_N(\mu_NS^N_{tN^2}|\nu_{\rho(t,\cdot)}(\cdot)) = o(N^d),
\]

provided \( \rho(t,u) \) is the solution of \(2.5\).
In view of this result, we can weaken the assumptions of Theorem 2.1 and assume only that the initial state has relative entropy of order \(o(N^d)\) with respect to \(\nu_{\rho_0(\cdot)}\).

3. Relative entropy estimates

We introduce in this section some auxiliary measures which will play a central role in the proof of Theorem 2.1. The statements presented here appeared essentially in the same form in [4] and [8]. We include their proof in sake of completeness.

Fix a profile \(\rho_0\) constant along the drift direction and bounded away from 0 and 1 as in (2.4). Denote by \(\rho(t,u)\) the smooth solution of the parabolic equation (2.4). Fix \(0 < \alpha < 1\). For \(N \geq 1\), denote by \(f_t^N\) the density of \(\mu^N S_t^N\) with respect to \(\nu_\alpha^N\).

An elementary computation shows that \(f_t^N\) is the solution of

\[
\partial_t f_t^N = N^2 L_N^* f_t^N,
\]

where \(L_N^*\) is the adjoint of the generator \(L_N\) in \(L^2(\nu_\alpha^N)\).

Denote by \(\mathfrak{F}\) the space of functions \(f: [0,1] \times \{0,1\}^{zd} \rightarrow \mathbb{R}\) such that

1. There exists a finite set \(\Lambda\) such that for each \(\beta\) in \([0,1]\) the support of \(f(\beta,\cdot)\) is contained in \(\Lambda\).
2. For each configuration \(\eta\), \(f(\cdot, \eta)\) is a smooth function.
3. For each density \(\beta\), the cylinder functions \(f(\beta,\cdot)\), \(f_1(\beta,\cdot)\) have zero mean with respect to \(\nu_\beta\). Here, \(f_1(\beta,\cdot)\) stands for the derivative of \(f(\beta,\cdot)\) with respect to the first coordinate.

Let \(\lambda: \mathbb{R}_+ \times \mathbb{T}^d \rightarrow \mathbb{R}\) be defined by

\[
\lambda(t,u) = \log \frac{\rho(t,u)(1-\alpha)}{\alpha[1-\rho(t,u)]},
\]

\(\lambda(t,u)\) is well defined because the solution \(\rho(t,u)\) of the hydrodynamic equation (2.4) is bounded away from 0 and 1. Denote by \(\psi_i^N(\eta)\) the density of \(\nu_{\rho_0(\cdot)}^N\) with respect to \(\nu_\alpha^N\):

\[
\psi_i^N(\eta) = \frac{1}{Z_i^N} \exp \left\{ \sum_{x \in \mathbb{T}^d_N} \lambda(t,x/N)\eta(x) \right\},
\]

where \(Z_i\) is a renormalizing constant.

For functions \(f_i\) in \(\mathfrak{F}\), \(1 \leq i \leq d\), a time \(t \geq 0\) and integers \(\ell \ll M \ll N\), define the density \(\psi_{i,N}(\eta) = \psi_{i,N}^M(\eta)\) with respect to the reference measure \(\nu_\alpha^N\) by

\[
\psi_{i,N}(\eta) = \frac{1}{Z_i^N} \exp \left\{ \sum_{x \in \mathbb{T}^d_N} \lambda(t,x/N)\eta(x) \right\} \times
\]

\[
\times \exp \left\{ - \frac{1}{N-1} \sum_{i=1}^d \sum_{x \in \mathbb{T}^d_N} \partial_{u_i} \lambda(t,x/N) \frac{1}{|\Lambda_{\ell'}|} \sum_{y \in \Lambda_{\ell'}} f_i(\eta^M(x),\tau_{x,y}) \right\},
\]

where \(Z_i^N\) is a renormalizing constant, \(\Lambda_K = \{-K,\ldots,K\}^d\) is a cube of length \(2K+1\) centered at the origin, \(\eta^K(x)\) is the mean density of particles in \(x + \Lambda_K\):

\[
\eta^K(x) = \frac{1}{|\Lambda_K|} \sum_{y \in x + \Lambda_K} \eta(y)
\]

and \(\ell' = \ell - A\) for a finite constant \(A\) chosen for the support of \(f_i(\beta,\tau_{y})\) to be contained in \(\Lambda_{\ell}\) for all \(1 \leq i \leq d\), \(|y| \leq \ell - A\). Throughout this article, \(A\) stands
for a finite integer related to the support of the transition probability \( p(\cdot) \) or to the support of some local function.

In the following, we will need to take \( M \) as a function of \( N \) and \( \ell \) as an independent integer which increases to \( \infty \) after \( N \). In fact we will require \( M \) to be such that

\[
\lim_{N \to \infty} \frac{|\Lambda_M|}{N} = 0, \quad \lim_{N \to \infty} \frac{N}{M|\Lambda_M|} = 0. \tag{3.2}
\]

We present three elementary results which illustrate some properties of the density \( \psi^\alpha_N(\eta) \). Denote by \( s_i \) the smallest integer \( m \) with the property that the common support of the local functions \( f_i(\beta, \cdot) \), \( 1 \leq i \leq d, \ 0 \leq \beta \leq 1 \), is contained in \( \Lambda_m \).

**Lemma 3.1.** Assume that \( s_i \leq \ell \leq M \) and that \( \lim_{N \to \infty} |\Lambda_M|/N = 0 \). Fix a density \( f \) with respect to the reference measure \( \nu_N^\alpha \). There exists a finite constant \( C \), depending only on \( \ell \) and \( \rho(t, u) \), such that

\[
\left| H_N(f | \nu_N^\alpha |) - H_N(f | \psi^\alpha_N) \right| \leq CN^{d-1}
\]

for all \( N \geq 1 \).

In the statement of this result and frequently in this article, if measures \( \mu, \nu \) have density \( f, g \) with respect to the reference measure \( \nu^\alpha_N \), to keep notation simple, we denote by \( H_N(f | g) \) the entropy of \( f \nu^\alpha_N \) with respect to \( g \nu^\alpha_N \) and by \( E_f(\cdot) \) the expectation with respect to \( f \nu^\alpha_N \).

**Proof.** Fix a density \( f \). By the explicit formula for the entropy, the difference \( H_N(f | \nu_N^\alpha) - H_N(f | \psi_N^\alpha) \) is equal to

\[
\int f \log \frac{\psi_N^\alpha}{\psi^\alpha_N} d\nu_N^\alpha = O(N^{d-1}) - \log \frac{Z^\ell_1}{Z^\ell},
\]

In particular, we just need to show that the second term on the right hand side is absolutely bounded by \( CN^{d-1} \). By definition of the renormalizing constant \( Z^\ell_1, Z^\ell \), the logarithm is equal to

\[
\log E_{\nu_N^\alpha}(\exp \left\{ -N^{-1} \sum_{i=1}^d \sum_{x \in \mathbb{T}_N^d} \partial u_i \lambda(t, x/N)(A_{t, \ell, i}) (\nu^\alpha_N) \right\}), \tag{3.3}
\]

where, for a function \( \mathfrak{f} \) in \( \mathfrak{F} \) and a positive integer \( \ell \),

\[
(A_{t, \ell, i}) (\beta, \eta) = \frac{1}{|\Lambda_{\ell'}|} \sum_{y \in \Lambda_{\ell'}} \mathfrak{f}(\beta, \tau_{y} \eta).
\]

By Jensen inequality, \( (3.3) \) is bounded below by \( -CN^{d-1} \). On the other hand, since \( \ell \leq M \), \( A_{t, \ell, i}(\nu^\alpha_M(0), \eta) \) depends on the configuration \( \eta \) only through \( \eta(z) \) for \( z \) in \( \Lambda_M \). In particular, since \( \nu^\alpha_N \) is a product measure, by Hölder inequality, \( (3.3) \) is bounded above by

\[
\frac{1}{d|\Lambda_M|} \sum_{i=1}^d \sum_{x \in \mathbb{T}_N^d} \log E_{\nu_N^\alpha}(\exp \left\{ -d|\Lambda_M|N^{-1} \partial_u \lambda(t, x/N)(A_{t, \ell, i}) (\nu^\alpha_N) \right\}).
\]

Since by assumption \( |\Lambda_M|N^{-1} \) vanishes as \( N \uparrow \infty \), we may expand the exponential up to the second order to show that this expression is less than or equal to \( CN^{d-1} \). This concludes the proof of the lemma. \( \square \)
Taking \( f = \psi^N_{t,i} \) in Lemma 3.1 we obtain a bound on the entropy of \( \psi^N_{t,i} \) with respect to \( \nu^N_{\rho(t,i)} \).

**Corollary 3.2.** Under the assumptions of Lemma 3.1, there exists a finite constant \( C \), depending only on \( f \) and \( \rho(t,u) \), such that

\[
H_N(\psi^N_{t,i} | \nu^N_{\rho(t,i)}) \leq C N^{d-1}
\]

for all \( N \geq 1 \).

**Corollary 3.3.** Fix a smooth function \( H : \mathbb{T}^d \to \mathbb{R} \) and a function \( g \) in \( \mathcal{F} \). There exists a finite constant \( C_0 \), depending only on \( f \), \( g \), \( H \) and \( \rho(t,u) \), such that

\[
\left| E_{\psi^N_{t,i}} \left[ N^{-d} \sum_{x \in \mathbb{T}^d_N} H(x/N)(A_t g)(\eta^M(x), \tau_x \eta) \right] - E_{\nu^N_{\rho(t,i)}} \left[ N^{-d} \sum_{x \in \mathbb{T}^d_N} H(x/N)(A_t g)(\eta^M(x), \tau_x \eta) \right] \right| \leq C_0 \sqrt{\frac{|\Lambda_M|}{N}}.
\]

**Proof.** By the entropy inequality

\[
H_N(\psi^N_{t,i} | \nu^N_{\rho(t,i)}) \leq \gamma N^{d-1} + \frac{1}{\gamma N^{d-1}} \log E_{\nu^N_{\rho(t,i)}} \left[ \exp \left\{ \gamma N^{-1} \sum_{x \in \mathbb{T}^d_N} H(x/N)(A_t g)(\eta^M(x), \tau_x \eta) \right\} \right]
\]

for every \( \gamma > 0 \). By Corollary 3.2, the first term is bounded by \( C \gamma^{-1} \). On the other hand, repeating the argument presented in the proof of Lemma 3.1 we show that the second term is less than or equal to

\[
E_{\nu^N_{\rho(t,i)}} \left[ N^{-d} \sum_{x \in \mathbb{T}^d_N} H(x/N)(A_t g)(\eta^M(x), \tau_x \eta) \right] + \frac{C \gamma |\Lambda_M|}{N} E_{\nu^N_{\rho(t,i)}} \left[ N^{-d} \sum_{x \in \mathbb{T}^d_N} H(x/N)^2(A_t g)(\eta^M(x), \tau_x \eta)^2 \right]
\]

provided that \( \gamma |\Lambda_M| N^{-1} \) vanishes as \( N \uparrow \infty \). In this formula, \( C \) is a finite constant which depends on \( g \) and \( H \). In particular, the difference appearing inside the absolute value in the statement of the corollary is less than or equal to

\[
\frac{C}{\gamma} + \frac{C \gamma |\Lambda_M|}{N}.
\]

Taking \( \gamma = \sqrt{N/|\Lambda_M|} \), we show that this expression is bounded by \( C \sqrt{\frac{|\Lambda_M|}{N}} \). Replacing \( H \) by \(-H\), we conclude the proof of the corollary. \( \square \)
4. Proof of Theorem \ref{thm:main}

We prove in this section Theorem \ref{thm:main}. In view of Lemma \ref{lem:main} Theorem \ref{thm:main} is a consequence of the following result.

**Proposition 4.1.** Fix a measure \(\mu^N\) such that \(H_N(\mu^N | \nu^N_{\rho(t)}) = o(N^d)\). Assume that the profile \(\rho_0\) satisfies \ref{eq:rho0}, \ref{eq:rho02}. There exist sequences \(\{f_{i,n}, n \geq 1\}, 1 \leq i \leq d\), of functions in \(\mathcal{N}\) such that

\[
\lim_{n \to \infty} \limsup_{t \to \infty} \limsup_{N \to \infty} N^{-d}H_N(\mu^N S^N_t | \psi^N_{i,f_n}) = 0
\]

for every \(t \geq 0\). In this formula, \(f_n = (f_{1,n}, \ldots, f_{d,n})\).

The proof of Proposition \ref{prop:4.1} is divided in several steps. To keep notation simple, denote by \(H^\ell_N(t)\) the relative entropy of \(\mu^N S^N_t\) with respect to \(\psi^N_{i,f}\):

\[
H^\ell_N(t) = H_N(\mu^N S^N_t | \psi^N_{i,f}).
\]

In view of Lemma \ref{lem:main} and of Gronwall inequality, it is enough to show that for every \(t \geq 0\),

\[
H^\ell_N(t) \leq o(N^d, f) + \gamma^{-1} \int_0^t ds H_N(\mu^N S^N_s | \nu^N_{\rho(s,.)})
\]

for some \(\gamma > 0\). Here, \(o(N^d, f)\) stands for a finite constant such that

\[
\lim_{n \to \infty} \limsup_{t \to \infty} \limsup_{N \to \infty} N^{-d}o(N^d, f_n) = 0.
\]

The sequence \(\{f_{i,n}, n \geq 1\}\) is given by Theorem \ref{thm:approximation}. To keep notation simple, we perform all computations for a single function \(f = (f_1, \ldots, f_d)\) and then replace it by the sequence \(f_n\).

Recall that \(M\) depends on \(N\) through the relations \ref{eq:M} and that \(\ell\) is an integer independent of \(N\) which increases to infinity after \(N\). To prove \ref{prop:4.1}, we start computing the time derivative of the entropy \(H^\ell_N(t)\). On the one hand, a celebrated estimate of \ref{est:entropy} gives that

\[
\frac{d}{dt} H^\ell_N(t) \leq \int f^N_i \left\{ \frac{N^2L_\alpha^N \psi^N_{i,f}}{\psi^N_{i,f}} - \partial_t \log(\psi^N_{i,f}) \right\} d\nu^N_{\alpha}.
\]

On the other hand, a straightforward computation, presented in section \ref{sec:proof}, shows that the expression inside braces in the previous integral is equal to

\[
N \sum_{i=1}^d \sum_{x \in \mathcal{T}^d_N} (\partial_{u_i}) \lambda(t, x/N) \left\{ \tau_x W^*_i - L^*_N(A_x f_i)(\eta^M(x), \tau_x \eta) \right\}
\]

\[
+ (1/2) \sum_{i,j=1}^d \sum_{x \in \mathcal{T}^d_N} (\partial^2_{u_i u_j}) \lambda(t, x/N) \tau_x G_{i,j}(\eta)
\]

\[
+ (1/2) \sum_{i,j=1}^d \sum_{x \in \mathcal{T}^d_N} (\partial_{u_i}) \lambda(t, x/N) (\partial_{u_j}) \lambda(t, x/N) \tau_x H_{i,j}(\eta)
\]

\[
- \sum_{x \in \mathcal{T}^d_N} (\partial_{x}) \lambda(t, x/N) \eta(x) + E_{\psi_{i,f}} \left[ \sum_{x \in \mathcal{T}^d_N} (\partial_{x}) \lambda(t, x/N) \eta(x) \right] + o(N^d).
\]
In this formula, \( o(N^d) \) is a term of order \( N^d \ell M^{-1} \ll N^d \), \( E_\psi \) stands for the expectation with respect to \( \psi_t^N dv^N_\alpha \), \( W^*_i \) is the current in the \( i \)-th direction for the adjoint process and \( G_{i,j}(\eta) \), \( H_{i,j}(\eta) \) are local functions given by:

\[
W^*_i = \sum_{y \in \mathbb{Z}^d} p^*(y) y_i \eta(0)[1 - \eta(y)], \quad G_{i,j}(\eta) = \sum_{y \in \mathbb{Z}^d} p^*(y) y_i y_j \eta(0)[1 - \eta(y)],
\]

\[
H_{i,j}(\eta) = \sum_{y \in \mathbb{Z}^d} p^*(y) \eta(0)[1 - \eta(y)] \{ y_i - \nabla_{0,y} \Gamma_{f_i(\eta^N(x), \cdot)} \} \times \{ y_j - \nabla_{0,y} \Gamma_{f_j(\eta^N(x), \cdot)} \}.
\]

Here and below, \( \nabla_{x, h} \) is the operator defined by

\[
(\nabla_{x, y} f)(\eta) = f(\sigma^{x-y} \eta) - f(\eta)
\]

and, for a local function \( h \), \( \Gamma_h \) is the formal sum

\[
\Gamma_h = \sum_{x \in \mathbb{Z}^d} \tau_x h.
\]

Since \( h \) is a local function, even if the sum of translations is not defined, the gradient \( \nabla_{0,y} \Gamma_h \) makes sense because only a finite number of terms do not vanish.

We consider separately the sums in (4.3). The goal is to replace each one by a simpler expression and a remainder denoted by \( o(N^d) \). The remainder \( o(N^d) \) stands for an expression which may depend on time and on the configuration but such that

\[
\lim_{t \to \infty} \lim_{N \to \infty} N^{-d} \left| \int_0^t ds o(N^d) f^*_s dv^N_\alpha \right| = 0
\]

for every \( t > 0 \). If the remainder vanishes only after taking the limit in \( f_n \), we denote it by \( o(f_n, N^d) \) and we require

\[
\lim_{n \to \infty} \lim_{t \to \infty} \lim_{N \to \infty} N^{-d} \left| \int_0^t ds o(f_n, N^d) f^*_s dv^N_\alpha \right| = 0
\]

for every \( t > 0 \).

We start with the last term of (4.3). By Corollary (3.3) we may replace the expectation with respect to \( \psi_t^N dv^N_\alpha \) with an expectation with respect to \( \nu^N_\rho(t, \cdot) \) paying a price of order \( N^d(\sqrt{|A_M|}/N) \). After this modification, the last line of (4.3), becomes

\[
- \sum_{x \in \mathbb{Z}^d} (\partial_t \lambda)(t, x/N) \{ \eta(x) - \rho(t, x/N) \} + o(N^d).
\]

Since \( \partial_t \lambda \) is a smooth function, we may further replace \( \eta(x) \) by \( \eta^N(x) \) paying a price absolutely bounded by \( C\ell^2 N^{-d-2} \) for some finite constant \( C \).

To estimate the order \( N^{d+1} \) of (4.3), we first take advantage of the assumption that the solution \( \rho(t, u) \) is constant along the drift direction.

By paying a price of order \( O(\ell^d N^{-d-1}) \), we may replace the current \( W^*_i \) by an average \( |A_\ell|^{-1} \sum_{y \in A_\ell} \tau_y W^*_i \). Here again one should keep in mind, that the average is in fact carried over a cube of length slightly smaller than \( 2\ell + 1 \) to ensure that all local functions \( \tau_y W^*_i \) have support contained in \( A_\ell \).
Recall that \( q = (q_1, \ldots, q_d) \) denotes the drift of particles. The average of the current \( W_i^* \) can be written as

\[
\frac{1}{|A_{\ell_i}|} \sum_{z \in A_{\ell_i}} \tau_z W_i^* = q_i \left\{ \eta^\ell(0) - 2\eta^\ell(0)\eta^\ell(0) + \eta^\ell(0)^2 \right\} + \frac{1}{|A_{\ell_i}|} \sum_{z \in A_{\ell_i}} w_i^*(\eta^\ell(0), \tau_z \eta),
\]

where \( q_i^* = -q_i \) and

\[
w_i^*(\alpha, \eta) = - \sum_{y \in \mathbb{Z}^d} p^\ast(y) y_i [\eta(0) - \alpha] [\eta(y) - \alpha] - \alpha \sum_{y \in \mathbb{Z}^d} p^\ast(y) y_i [\eta(y) - \eta(0)].
\]

The first term of the current gives no contribution since for any function \( J \),

\[
N \sum_{i=1}^{d} \sum_{x \in \mathbb{T}_N} (\partial_{u_i} \lambda)(t, x/N) q_i J(\eta^\ell(0), \eta^\ell(x)) = 0
\]

because \( \sum_{1 \leq i \leq d} q_i (\partial_{u_i} \lambda)(t, u) = \{ \rho(t, u)[1 - \rho(t, u)] \}^{-1} \sum_{1 \leq i \leq d} q_i (\partial_{u_i} \rho)(t, u) \) vanishes for all \((t, u)\). The first term of (13) becomes therefore

\[
N \sum_{i=1}^{d} \sum_{x \in \mathbb{T}_N} (\partial_{u_i} \lambda)(t, x/N) \tau_x \left\{ (A_{\ell_i} w_i^*)(\eta^\ell(0), \eta) - L^*_N(A_{\ell_i})(\eta^M(0), \eta) \right\}.
\]

To ensure that the function which appears in \( A_{\ell_i} w_i^* \) has mean zero with respect to the all canonical measures on the cube \( A_{\ell_i} \), we further replace \( A_{\ell_i} w_i^* \) by \( A_{\ell_i}^0 w_i^* \), where

\[
(A_{\ell_i}^0 w_i^*)(\alpha, \eta) = (A_{\ell_i} w_i^*)(\alpha, \eta) + q_i \frac{\alpha(1 - \alpha)}{|A_{\ell_i}| - 1}.
\]

This replacement is permitted because \( \sum_i q_i \partial_{u_i} \rho = 0 \).

Following the nongradient method, we add and subtract \( \sum_{1 \leq j \leq d} d_{i,j}(\eta^\epsilon_N(0)) - \eta^\epsilon_N(0) \). Since the diffusion coefficient is smooth, this expression is equal to \( \sum_{1 \leq j \leq d} \{ d_{i,j}(\eta^\epsilon_N(0)) - d_{i,j}(\eta^\epsilon_N(0)) \} + (\epsilon_N)^{-2} \), where \( d_{i,j} \) stands for the integral of \( D_{i,j} \). In particular, after a summation by parts, the first line of (13), maybe rewritten as

\[
N \sum_{i=1}^{d} \sum_{x \in \mathbb{T}_N} (\partial_{u_i} \lambda)(t, x/N) \tau_x V_{i}^{\epsilon_N,M,\ell}(\eta) \tag{4.4}
\]

\[
+ \sum_{i,j=1}^{d} \sum_{x \in \mathbb{T}_N} (\partial_{u_i u_j}^2 \lambda)(t, x/N) d_{i,j}(\eta^\epsilon_N(x)) + O(N^{d-1}),
\]

where

\[
V_{i}^{K, M, \ell}(\eta) = (A_{\ell_i}^0 w_i^*)(\eta^\ell(0), \eta) + \sum_{j=1}^{d} D_{i,j}(\eta^K(0)) [\eta^K(e_j) - \eta^K(0)] - L^*_N(A_{\ell_i})(\eta^M(0), \eta).
\]

It is not difficult to see that there exists a finite constant \( C(\alpha) \) such that

\( H(\mu_N | \nu_N) \leq C(\alpha) N^d \) for every probability measure \( \mu_N \) on \( \{0, 1\}^{T_2} \). In particular, by the usual two blocks estimate, since \( d_{i,j} \) is Lipschitz continuous, for
By the non-gradient method, the first line can be shown to be of order \( \ell \). This means that we suppress all jumps from \( \Lambda^\ell \). In particular, this generator leaves \( \eta^\ell(0) \) invariant and it is acting in fact only on the second coordinate. This replacement is one of the main technical points of the article. It is here that the special form of \( \psi^\ell_\star \) plays an important role, that we need the spatial averages and the particular size of \( M \) and \( \ell \) presented in (3.2).

Up to this point, we transformed the first line of (1.3) in

\[
N \sum_{i=1}^{d} \sum_{x \in \mathbb{T}_N} (\partial_{u_i} \lambda)(t, x/N) \tau_x V_i^\ell (\eta)
\]

(4.5)

\[
+ \sum_{i,j=1}^{d} \sum_{x \in \mathbb{T}_N} (\partial^2_{u_i,u_j} \lambda)(t, x/N) d_{i,j}(\eta^\ell(x)) + o(N^d),
\]

where

\[
V_i^\ell (\eta) = (A_i^\ell w_i^\ell)(\eta^\ell(0), \eta) + \sum_{j=1}^{d} D_{i,j}(\eta^\ell(0)) [\eta^\ell(e_j) - \eta^\ell(0)] - \Lambda^{\star \ell}(A_{\ell f_i})(\eta^\ell(0), \eta).
\]

By the non-gradient method, the first line can be shown to be of order \( o(f, N^d) \). Details are given in subsection 3.3.

It remains to consider the second and third line of (1.3). By the one block estimate the second line of (1.3) is equal to

\[
(1/2) \sum_{i,j=1}^{d} \sum_{x \in \mathbb{T}_N} (\partial^2_{u_i,u_j} \lambda)(t, x/N) \sigma_{i,j} \tau_x F(\eta^\ell(0)) + o(N^d),
\]

where \( \sigma_{i,j} \) is the symmetric matrix defined just after (2.5) and \( F(a) = a(1-a) \).

For \( 1 \leq i,j \leq d \), let

\[
J_{i,j}(\beta) = 2\beta(1-\beta) \{ D_{i,j}(\beta) - \beta \sigma_{i,j} \}.
\]

(4.6)
In particular, in formula (4.7), we may replace the terms

\[ \partial_i \lambda(t, x/N)(\partial_{u_j} \lambda)(t, x/N) \sigma_{i,j} F(\eta^f(x)) \]

\[ + (1/2) \sum_{i,j=1}^{d} \sum_{x \in \mathcal{T}_N^d} (\partial_i \lambda)(t, x/N)(\partial_{u_j} \lambda)(t, x/N) J_{i,j}(\eta^f(x)) + o(f_n, N^d). \]

In conclusion, we proved that (4.3) is equal to

\[ \leq G_{i,j}^m(t, x/N) H_{i,j}^m(\eta^f(x)) \]

\[ - \sum_{x \in \mathcal{T}_N^d} (\partial_i \lambda)(t, x/N) \{ \eta^f(x) - \rho(t, x/N) \} + o(f_n, N^d). \]

where

\[ G_{i,j}^1(t, u) = (\partial^2_{u_i u_j} \lambda)(t, u), \quad H_{i,j}^1(\beta) = d_{i,j}(\beta) + (1/2) \sigma_{i,j} F(\beta), \]

\[ G_{i,j}^2(t, u) = (\partial_i \lambda)(t, u)(\partial_{u_j} \lambda)(t, u), \quad H_{i,j}^2(\beta) = (1/2) \{ J_{i,j}(\beta) + \sigma_{i,j} F(\beta) \}. \]

An integration by parts shows that

\[ \int_{\mathbb{T}_N^d} du G_{i,j}^m(t, u) H_{i,j}^m(\rho(t, u)) = 0. \]

In particular, in formula (4.7), we may replace the terms \( H_{i,j}^m(\eta^f(x)) \) by \( H_{i,j}^m(\eta^f(x)) - H_{i,j}^m(\rho(t, x/N)) \) paying a price of order \( o(N^d) \). A further elementary computation gives that

\[ \sum_{m=1}^{2} \sum_{i,j=1}^{d} \int_{\mathbb{T}_N^d} du G_{i,j}^m(t, u)(H_{i,j}^m)'(\rho(t, u)) = (\partial_i \lambda)(t, u) \]

for every \( t \) and \( u \), where \( (H_{i,j}^m)' \) stands for the derivative of \( H_{i,j}^m \). Therefore, (4.7) becomes

\[ \sum_{m=1}^{2} \sum_{i,j=1}^{d} G_{i,j}^m(t, x/N) B_{i,j}^m(\eta^f(x), \rho(t, x/N)) + o(f_n, N^d), \]

where

\[ B_{i,j}^m(a, b) = H_{i,j}^m(a) - H_{i,j}^m(b) - (H_{i,j}^m)'(b) [a - b]. \]

At this point we may repeat the standard arguments of the relative entropy method do conclude. We refer to Chap. 6 of [10] for details.

5. Hilbert space of variances

We prove in this section the existence of functions \( f_1, \ldots, f_d \) in \( \mathfrak{g} \) which approximate the current in the Hilbert space of variances. We rely on recent results based on general duality presented in [10], [12].

For \( 0 \leq \alpha \leq 1 \), denote by \( \mathcal{G}_\alpha \) the space of cylinder functions \( g \) such that \( E_{\nu_\alpha}[g] = \partial_\alpha E_{\nu_\alpha}[g] = 0 \):

\[ \hat{g}(\alpha) = E_{\nu_\alpha}[g] = 0 \quad \text{and} \quad \hat{g}'(\alpha) = \frac{d}{d\beta} E_{\nu_\beta}[g] \bigg|_{\beta = \alpha} = 0. \]
For each function $g$ in $G_\alpha$ we define $\|g\|_\alpha$ by
\[
\|g\|_\alpha^2 = |g|_\alpha^2 + \|g\|_{-1,\alpha}^2,
\]
where
\[
|g|_\alpha^2 = \sup_{a \in \mathbb{R}^d} \left\{ 2 \sum_{i=1}^d a_i \sum_{x \in \mathbb{Z}^d} x_i < g; \eta(x) > \alpha - \frac{\chi(\alpha)}{2} a \cdot \sigma a \right\},
\]
\[
\|g\|_{-1,\alpha}^2 = \sup_{h \in \mathcal{G}_\alpha} \left\{ 2 < g, h > \alpha - < h, (-L^*)h > \alpha \right\}.
\]
In this formula, $\chi(\alpha) = \alpha(1 - \alpha)$, $a \cdot b$ stands for the inner product in $\mathbb{R}^d$ and $< \cdot, \cdot >_\alpha$ for the inner product in $G_\alpha$ given by
\[
< g, h >_\alpha = \sum_{x \in \mathbb{Z}^d} < g; \tau_x h >_\alpha,
\]
where $< f_1; f_2 >_\alpha$ denotes the covariance of $f_1, f_2$ with respect to $\nu_\alpha$. Notice that in the sums which appear in the formulas above, all but a finite number of terms vanish because $\nu_\alpha$ is a product measure. Theorem [5.1] is the main result of this section.

**Theorem 5.1.** There exist a smooth matrix-valued function $D(\alpha) = \{D_{i,j}(\alpha), 1 \leq i, j \leq d\}$ and a sequence of functions $\{f_{i,n}, n \geq 1\}$ in $\mathfrak{H}$, $1 \leq i \leq d$, such that
\[
\lim_{n \to \infty} \sup_{\alpha \in [0,1]} \|w_i^+(\alpha, \eta) + \sum_{j=1}^d D_{i,j}(\alpha)[\eta(e_j) - \eta(0)] - L^*f_{i,n}(\alpha, \eta)\|_\alpha = 0
\]
for $1 \leq i \leq d$. Moreover, for any vector $v$ in $\mathbb{R}^d$,
\[
\lim_{n \to \infty} \sum_{x \in \mathbb{Z}^d} < \sum_{j=1}^d v_j f_{j,n}(\alpha, \eta), (-L^*)\tau_x \sum_{j=1}^d v_j f_{j,n}(\alpha, \eta) >_\alpha = \chi(\alpha) v \cdot \{D(\alpha) - \alpha \sigma\} v
\]
uniformly in $\alpha$.

This result is a slight generalization of Corollary 10.1 and Lemma 10.4 in [8], proved in [7] using results presented in [13]. We have the advantage here to obtain uniformity up to the boundary. In sake of completeness, we present a simpler proof relying on the generalized duality developed in [10], [12].

To keep notation simple, we prove Theorem [5.1] for the current $w_i$ obtained from $w_i^*$ by replacing $p^*(\cdot)$ by $p(\cdot)$ and for the generator $L$ in place of $L^*$.

**Duality.** For each $n \geq 0$, denote by $\mathcal{E}_n$ the subsets of $\mathbb{Z}^d$ with $n$ points and let $\mathcal{E} = \cup_{n \geq 0} \mathcal{E}_n$ be the class of finite subsets of $\mathbb{Z}^d$. For each $A$ in $\mathcal{E}$, let $\Psi_A$ be the local function
\[
\Psi_A = \prod_{x \in A} \frac{\eta(x) - \alpha}{\sqrt{\chi(\alpha)}}.
\]
By convention, $\Psi_\emptyset = 1$. It is easy to check that $\{\Psi_A, A \in \mathcal{E}\}$ is an orthonormal basis of $L^2(\nu_\alpha)$. For each $n \geq 0$, denote by $\mathcal{D}_n$ the subspace of $L^2(\nu_\alpha)$ generated by $\{\Psi_A, A \in \mathcal{E}_n\}$, so that $L^2(\nu_\alpha) = \oplus_{n \geq 0} \mathcal{D}_n$. Functions in $\mathcal{D}_n$ are said to have degree $n$. 
Consider a local function \( f \). Since \( \{ \Psi_A : A \in \mathcal{E} \} \) is a basis of \( L^2(\nu_\alpha) \), we may write
\[
f = \sum_{n \geq 0} \sum_{A \in \mathcal{E}_n} f(\alpha, A) \Psi_A .
\]

Note that the coefficients \( f(\alpha, A) \) depend not only on \( f \) but also on the density \( \alpha \). Since \( f \) is a local function, \( \mathcal{f} : \mathcal{E} \to \mathbb{R} \) is a function of finite support.

Fix a local function \( f \) and denote by \( f(\alpha, A) \) its Fourier coefficients. \( f \) has zero mean with respect to \( \nu_\alpha \) if and only if \( f(\alpha, \phi) = 0 \). It belongs to \( \mathcal{G}_\alpha \) if and only if \( f(\alpha, \phi) = 0 \) and the degree one part is such that
\[
\sum_{z \in \mathbb{Z}^d} f(\alpha, \{ z \}) = 0 .
\]

In this case, we may rewrite the degree one piece as
\[
\sqrt{\chi(\alpha)} \sum_{z \in \mathbb{Z}^d} f(\alpha, \{ z \})[\eta(z) - \eta(0)] .
\]

In conclusion, all functions \( f \) in \( \mathcal{G}_\alpha \) may be written as
\[
\sqrt{\chi(\alpha)} \sum_{z \in \mathbb{Z}^d} f(\alpha, \{ z \})[\eta(z) - \eta(0)] + \sum_{n \geq 2} \sum_{A \in \mathcal{E}_n} f(\alpha, A) \Psi_A .
\]

For \( n \geq 0 \), denote by \( \pi_n \) the projection on \( \mathcal{D}_n \) so that \( f = \sum_{n \geq 1} \pi_n f \) for \( f \) in \( \mathcal{G}_\alpha \). In the formula above, the first term corresponds to \( \pi_1 f \), the piece of \( f \) which has degree one, and the second term corresponds to \( (I - \pi_1) f \), the piece of degree greater or equal to 2.

It is clear that a local function of type \( h - \pi_x h \) belongs to the kernel of the inner product \( \ll \cdot, \cdot \gg_\alpha \) defined above. This is the case of \( \eta(z) - \eta(0) \) so that \( \| f \|_{-1, \alpha} = \| (I - \pi_1) f \|_{-1, \alpha} \). In contrast, any function \( h \) of degree greater or equal to 2 is such that
\[
\sum_{x \in \mathbb{Z}^d} x_i < h ; \eta(x) \gg_\alpha = 0
\]
for all \( i \) so that \( |h|_\alpha = 0 \). Therefore, \( |f|_\alpha = |\pi_1 f|_\alpha \) and
\[
\| f \|^2_\alpha = |\pi_1 f|^2_\alpha + \| (I - \pi_1) f \|^2_{-1, \alpha}
\]
for every local function \( f \) in \( \mathcal{G}_\alpha \).

**The generator on the Fourier coefficient.** Let \( \mathcal{E}_s \) be the class of all finite subsets of \( \mathbb{Z}^d = \mathbb{Z}^d \setminus \{0\} \) and let \( \mathcal{E}_{s,n} \) be the class of all subsets of \( \mathbb{Z}^d \) with \( n \) points. For a local function \( f \) in \( \mathcal{G}_\alpha \), define \( \mathfrak{f} : [0, 1] \times \mathcal{E}_s \to \mathbb{R} \) by
\[
(\mathfrak{f})(\alpha, A) = \sum_{z \in \mathbb{Z}^d} f(\alpha, [A \cup \{0\}] + z) ,
\]
where \( f(\alpha, \eta) \) belongs to \( \mathcal{G}_\alpha \) if and only if \( f(\alpha, \phi) = (\mathfrak{f})(\alpha, \phi) = 0 \). It has been in proved in \([12]\) that for every zero-mean local functions \( f, g \)
\[
\ll f, g \gg_\alpha = \ll (\mathfrak{f})(\alpha), (\mathfrak{f})(\alpha) \gg = \sum_{n \geq 0} \frac{1}{n + 1} \sum_{A \in \mathcal{E}_{s,n}} (\mathfrak{f})(\alpha, A) (\mathfrak{f})(\alpha, A) . \quad (5.3)
\]

For functions in \( \mathcal{G}_\alpha \), this sum starts from 1 because \( (\mathfrak{f})(\alpha, \phi) = (\mathfrak{f})(\alpha, \phi) = 0 \).

Observe that not every function \( f : [0, 1] \times \mathcal{E}_s \to \mathbb{R} \) is the image by \( \mathfrak{f} \) of some local function \( f \) since
\[
(\mathfrak{f})(\alpha, A) = (\mathfrak{f})(\alpha, S_z A) \quad (5.4)
\]
for all $z$ in $A$. Here, $S_z A$ is the set defined by

$$S_z A = \begin{cases} A - z & \text{if } z \notin A, \\ (A - z)_{0, -z} & \text{if } z \in A. \end{cases}$$

Let $f_* : [0, 1] \times E_* \to \mathbb{R}$ be a finitely supported function satisfying \( f_* \). Define $f : [0, 1] \times E \to \mathbb{R}$ by

$$f(\alpha, B) = \begin{cases} |B|^{-1} f_*(\alpha, B \setminus \{0\}) & \text{if } B \ni 0 \\ 0 & \text{otherwise}. \end{cases} \quad (5.5)$$

An elementary computations shows that $\mathcal{F} f(\alpha, \eta) = f_*$, if $f(\alpha, \eta)$ is the local function whose Fourier coefficients are $f(\alpha, A)$. Notice that $f(\alpha, \eta)$ belongs to $\mathcal{G}_\alpha$ if $f_*(\alpha, \phi) = 0$.

For any local function $f$, $\mathcal{L}(L f) = \mathcal{L}_\alpha \mathcal{F} f$, provided

$$\mathcal{L}_\alpha = \mathcal{L}_* + (1 - 2\alpha) \mathcal{L}_d + \sqrt{\chi(\alpha)} \{ \mathcal{L}_+ + \mathcal{L}_- \}$$

and, for $A \in E_*$, $\nu : E_* \to \mathbb{R}$ a finitely supported function,

$$(\mathcal{L}_* \nu)(B) = (1/2) \sum_{x, y \in E_*} s(y - x) [\nu(B_x, y) - \nu(B)] + \sum_{y \notin B} s(y) [\nu(S_y B) - \nu(B)],$$

$$\mathcal{L}_d(\nu)(A) = \sum_{x, y \in A : x, y \notin A} a(y - x) [\nu(A_x, y) - \nu(A)] + \sum_{y \notin A : y \notin 0} a(y) [\nu(S_y A) - \nu(A)],$$

$$\mathcal{L}_+(\nu)(A) = 2 \sum_{x \in A : y \notin A} a(y - x) \nu(A \setminus \{y\}) + 2 \sum_{x \in A : y \notin A} a(x) [\nu(A \setminus \{x\}) - \nu(S_x [A \setminus \{x\}]),$$

$$\mathcal{L}_-(\nu)(A) = 2 \sum_{x \notin A : y \notin A} a(y - x) \nu(A \cup \{y\}).$$

In this formula, $A_{x,y}$ is the set defined by

$$A_{x,y} = \begin{cases} (A \setminus \{x\}) \cup \{y\} & \text{if } x \in A, y \notin A, \\ (A \setminus \{y\}) \cup \{x\} & \text{if } y \in A, x \notin A, \\ A & \text{otherwise}. \end{cases}$$

**Hilbert spaces.** For two local functions $f, g$, let

$$\langle f, g \rangle_{\alpha, 1} = \langle f, (-L^*) g \rangle_{\alpha}$$

and let $H_1(\alpha)$ be the Hilbert space generated by local functions $f$ and the inner product $\langle \cdot, \cdot \rangle_{\alpha, 1}$. Denote by $\langle \cdot, \cdot \rangle_{\alpha}$ the scalar product on $E_*$ defined by

$$\langle f, g \rangle_{\alpha} = \sum_{n \geq 0} \frac{1}{n + 1} \sum_{A \in E_n} f(\alpha, A)(\mathcal{L}_* g)(\alpha, A)$$

and by $\mathcal{H}_n$ the Hilbert space generated by the finite supported functions endowed with the previous scalar product. From the previous definitions, for every local function $f, g$,

$$\langle f, g \rangle_{1, \alpha} = \langle \mathcal{F} f, \mathcal{F} g \rangle_{1}$$
Let \( w_\alpha \) \( z_\eta \) denote the first piece, which has degree 2, by \( \lambda > 0 \) for every \( \alpha \). Let \( H_{-1} \) the Hilbert space generated by the local functions and the semi-norm \( \| \cdot \|_{-1} \). In the same way, for a finitely supported function \( f : \mathcal{E}_* \to \mathbb{R} \), let

\[
\| f \|_{-1}^2 = \sup_g \left\{ 2 < f, g > - < g, g >_{1,\alpha} \right\},
\]

where the supremum is carried over all local functions \( g \). Denote by \( \mathcal{H}_{-1} \) the Hilbert space induced by the finitely supported functions \( f : \mathcal{E}_* \to \mathbb{R} \) and the semi-norm \( \| \cdot \|_{-1} \). By the identities for the \( L^2 \) and the \( H_1 \) norms, we obtain that

\[
\| f(\alpha, \eta) \|_{-1,\alpha}^2 = \| (\mathcal{I} f)(\alpha, \cdot) \|_{-1}^2 \tag{5.6}
\]

**The currents.** Recall the definition of the current \( w_i(\alpha, \eta) \) given in section 4. \( w_i \) is obtained from \( w_i^* \) by replacing \( p^*(\cdot) \) by \( p(\cdot) \) and can be expressed as

\[
w_i = -\alpha(1 - \alpha) \sum_{y \in \mathbb{Z}^d} p(y) y_i \Psi_{0,0} - \alpha \sum_{y \in \mathbb{Z}^d} p(y) y_i \{ \eta(y) - \eta(0) \}.
\]

Denote the first piece, which has degree 2, by \( \alpha(1 - \alpha)w_i^0 \). On the other hand, since \( \eta(e_k) - \eta(0) = \eta(e_k + x) - \eta(x) \) for the norm \( \| \cdot \|_\alpha \) for any \( x \), the piece which has degree one is equal to \( \alpha \sum_{y \in \mathbb{Z}^d} \sum_{1 \leq j \leq d} p(y) y_i y_j \{ \eta(e_j) - \eta(0) \} \). Then

\[
w_i = \alpha(1 - \alpha)w_i^0 - \alpha \sum_{j=1}^d \sigma_{i,j} [\eta(e_j) - \eta(0)].
\]

Let \( \mathfrak{w}_i = \mathcal{I} w_i^0 \). An straightforward computation gives that

\[
\mathfrak{w}_i(\alpha, \{ z \}) = -2 z_i a(z)
\]

for \( z \neq 0 \) and \( \mathfrak{w}_i(\alpha, A) = 0 \) otherwise. Notice that \( \mathfrak{w}_i \) does not depend on \( \alpha \). We have now all elements to prove the main result of this section.

**Proof of Theorem 5.1.** Fix \( 1 \leq i \leq d \). By Theorem 4.1 in [12], \( \mathfrak{w}_i \) belongs to \( \mathcal{H}_{-1} \) because \( \mathfrak{w}_i(\alpha, \phi) = 0 \) and we are in \( d \geq 3 \).

It has been proved in Lemma 4.3 of [12] that for each \( \lambda > 0 \) there exists a solution \( \mathfrak{f}_i(\alpha, A) \) of the resolvent equation

\[
\lambda \mathfrak{f}_i - \mathcal{L}_\alpha \mathfrak{f}_i = \mathfrak{w}_i
\]

satisfying (5.5) and such that \( \mathfrak{f}_i(\alpha, \phi) = 0 \).

By Theorem 4.4 in [12], for any \( k \geq 1 \), there exists a finite constant \( C_k \) independent of \( \alpha \) and \( \lambda \) such that

\[
\lambda \sum_{n \geq 0} (1 + n)^k < \pi_n \mathfrak{f}_i, \lambda, \pi_n \mathfrak{f}_i, \lambda >_n + \sum_{n \geq 0} (1 + n)^k < \pi_n \mathfrak{f}_i, \lambda, (-\mathcal{L}_\alpha) \pi_n \mathfrak{f}_i, \lambda >_n \leq C_k
\]

for every \( \lambda > 0 \) and \( \alpha \) in \( [0,1] \). In this formula, \( \pi_n \) stands for the projection on \( \mathcal{E}_{\alpha,n} : (\pi_n f)(\alpha, A) = f(\alpha, A) \mathbf{1}\{A \in \mathcal{E}_{\alpha,n}\} \), and \( < \cdot, \cdot >_n \) for the inner product in \( \mathcal{E}_{\alpha,n} \).
with respect to the counting measure:

\[ <f, g>_n = \sum_{A \in \mathcal{E}_n} f(\alpha, A)g(\alpha, A). \]

The estimate is uniform in \( \alpha \) because the current \( w_i \) does not depend on \( \alpha \).

By section 6 of [12], for each \( z \) in \( \mathbb{Z}^d \), \( f_{i,\lambda}(\cdot, \{z\}) \) is a smooth function in \([0, 1] \) and there exists a subsequence \( \lambda_k \downarrow 0 \) such that \( f_{i,\lambda_k}(\alpha, \{z\}) \) converges uniformly, as well as its derivatives, to some smooth function \( f_i(\alpha, \{z\}) \).

By the proof of Lemma 2.8 of [11], taking a further subsequence, we may assume that \( -(\mathcal{L}_\alpha f_{i,\lambda_k})(\alpha, \cdot) \) converges weakly to \( w_i \) in \( \mathcal{H}_-1 \) for a countable dense subset of densities \( \alpha \) in \([0, 1] \). By Lemma 5.2 below, \( -(\mathcal{L}_\alpha f_{i,\lambda_k})(\alpha, \cdot) \) converges weakly to \( w_i \) in \( \mathcal{H}_-1 \) for all \( \alpha \) in \([0, 1] \).

Our goal is to replace the sequence \( f_{i,\lambda_k} \) by a sequence \( h_{i,n} \) of finite supported functions with all the above properties of \( f_{i,\lambda_k} \) and for which \( -(\mathcal{L}_\alpha h_{i,n})(\alpha, \cdot) \) converges strongly to \( w_i \) in \( \mathcal{H}_-1 \), uniformly in \( \alpha \).

For each \( \alpha \) fixed, we may take convex combinations of the functions \( f_{i,\lambda_k} \) to obtain a new sequence \( h_{i,n} \) such that \( -(\mathcal{L}_\alpha h_{i,n}) \) converges strongly to \( w_i \) in \( \mathcal{H}_-1 \). Lemma 5.2 below shows that the procedure can be made uniform in \( \alpha \). Indeed, fix \( \varepsilon > 0 \) and a finite set \( \{\alpha_j, 1 \leq j \leq m\} \) in \([0, 1] \). The standard procedure to derive a strong converging sequence from a weak, bounded converging sequence shows that there exist \( M \geq 1 \) and a probability \( \{\theta_1, \ldots, \theta_M\} \) in \( \{1, \ldots, M\} \), such that

\[ \max_{1 \leq j \leq m} \|\mathcal{L}_\alpha g(\alpha_j, \cdot) + w_i\|_{-1} \leq \varepsilon, \]

where

\[ g(\alpha, \cdot) = \sum_{l=1}^M \theta_l f_{i,\lambda_l}(\alpha_j, \cdot). \]

Notice that we are taking the same convex combination for all densities \( \alpha_j \). If \( m \) is equal to \( \delta^{-1} \), given by Lemma 5.2 below, and \( \alpha_j = j\delta \), by Lemma 5.2

\[ \sup_{\alpha \in [0,1]} \|\mathcal{L}_\alpha g(\alpha, \cdot) + w_i\|_{-1} \leq 2\varepsilon, \]

where \( g(\alpha, \cdot) \) is obtained from \( f_{i,\lambda}(\alpha, \cdot) \) through the same convex combination. We have thus constructed a convex combination which guarantees the strong convergence in \( \mathcal{H}_-1 \) for all values of \( \alpha \). That is, there exists a sequence \( h_{i,n}(\alpha, \cdot) \) such that

- For each \( n \geq 1 \), and each \( z \) in \( \mathbb{Z}^d \), \( g_{i,n}(\cdot, \{z\}) \) is a smooth function of \( \alpha \) which converges uniformly, as well as all its derivatives, to some smooth function \( f_i(\alpha, \{z\}) \).
- Each \( g_{i,n} \) satisfies (5.4) and \( g_{i,n}(\alpha, \phi) = 0 \) because the functions \( f_{i,\lambda_k} \) have this property.
- The sequence converges uniformly to \( w_i \) in \( \mathcal{H}_-1 \):

\[ \lim_{n \to \infty} \sup_{\alpha \in [0,1]} \|\mathcal{L}_\alpha g_{i,n}(\alpha, \cdot) + w_i\|_{-1} = 0. \]

It remains to replace the functions \( g_{i,n} \) by finite supported functions. Fix two integer \( m, \ell \) and let \( h_{i,n}(\alpha, A) = g_{i,n}(\alpha, A)1\{|A| \leq m, A < \Lambda_\ell\} \). The integers \( m, \ell \) which depend on \( n \) and increase to infinity with \( n \), will be chosen later. Here, \( A < \Lambda_\ell \) if there exists \( z \) in \( A \) such that \( S_z A \subset \Lambda_\ell \). In this way, \( h_{i,n} \) satisfies (5.4).
The sequence $h_{i,n}$ just defined has the first two properties of the sequence $g_{i,n}$ enumerated above because $m$ and $\ell$ increase to infinity as $n \uparrow \infty$. To prove the third one, recall from the computations performed after (4.12) in [9] that
\[
\mathcal{L}_\alpha g_{i,n}(\alpha, \cdot) - \mathcal{L}_\alpha h_{i,n}(\alpha, \cdot) \leq C_0 \sum_{k=1}^{m+1} (1+k) \| \pi_k g_{i,n}(\alpha, \cdot) - \pi_k h_{i,n}(\alpha, \cdot) \|_{g_k}^2 + \sum_{k \geq m} (1+k)^2 < \pi_k g_{i,n}(\alpha, \cdot), (\mathcal{L}_0 \pi_k g_{i,n})(\alpha, \cdot) >_k
\]
for some finite constant $C_0$ independent of $\alpha$. Here, $\| \cdot \|_{0,k}$ stands for the norm associated to the scalar product $< \cdot, \cdot >_k$ defined above. By (5.7), the second term on right hand side can be made uniformly small in $\alpha$ by choosing $m$ large enough because each function $g_{i,n}$ is obtained as convex combinations of the solution of the resolvent equation. For a fixed finite set $\alpha_1, \ldots, \alpha_r$, we may turn the first term as small as one wishes for $\{ \alpha_i \mid 1 \leq i \leq r \}$ by taking $\ell$ large enough. By Lemma 5.2 below, we may turn the estimate uniform in $\alpha$ because the functions $g_{i,n}$ are convex combinations of the solution of the resolvent equation.

For each fixed $n$, the functions $h_{i,n}(\alpha, \cdot)$ has a uniform support. Since $h_{i,n}(\alpha, \phi) = 0$, the local functions $f_{i,n}(\alpha, \eta)$ obtained from $h_{i,n}$ through (5.1) are in $\mathcal{F}$. We claim that the sequence $-\chi(\alpha)f_{i,n}(\alpha, \eta)$ has the properties required in the statement of the theorem. In view of the decomposition of the current $w_i$, by (5.1),
\[
\left\| w_i(\alpha, \eta) + \sum_{j=1}^{d} D_{i,j}(\alpha)[\eta(e_j) - \eta(0)] + \chi(\alpha)L f_{i,n}(\alpha, \eta) \right\|_{\alpha}^2 = \left\| \chi(\alpha)w_i^0 + \chi(\alpha)(I - \pi_1)L f_{i,n}(\alpha, \eta) \right\|_{-1,\alpha}^2 + \left\| \sum_{j=1}^{d} \{ D_{i,j}(\alpha) - \alpha \sigma_{i,j} \} [\eta(e_j) - \eta(0)] + \chi(\alpha)\pi_1 L f_{i,n}(\alpha, \eta) \right\|_{\alpha}^2.
\]
Since functions of degree 1 are in the kernel of the scalar product $\ll \cdot, \cdot \gg_\alpha$, we may replace $(I - \pi_1)L f_{i,n}$ by $L f_{i,n}$ on the first term on the right hand side. On the other hand, by definition of $D_{i,j}(\alpha)$, by identity (5.10) and since $\mathbb{F} w_i^0 = w_i$, the first term on the right hand side of (5.13) is equal to
\[
\chi(\alpha)^2 \left\| w_i + \mathcal{L}_\alpha h_{i,n}(\alpha, \cdot) \right\|_{-1}^2.
\]
This expression vanishes, as $n \uparrow \infty$, uniformly in $\alpha$, by construction of the sequence $h_{i,n}$.

On the other hand, an elementary computation, presented just after (5.4) in [12], shows that
\[
\pi_1 L f_{i,n}(\alpha, \eta) = \sum_{z \in \mathbb{Z}^d} a(z) h_{i,n}(\alpha, z)[\eta(z) - \eta(0)].
\]
Since $\eta(z) - \eta(0) = \sum_{1 \leq j \leq d} z_j [\eta(e_j) - \eta(0)]$ for the norm $| \cdot |_\alpha$, the second expression on the right hand side of (5.13) is equal to
\[
\left\| \sum_{j=1}^{d} \{ D_{i,j}(\alpha) - \alpha \sigma_{i,j} + h_{i,j,n}(\alpha) \} [\eta(e_j) - \eta(0)] \right\|_{\alpha}^2.
\]
where
\[ h_{i,j,n}(\alpha) = \chi(\alpha) \sum_{z \in \mathbb{Z}^d} a(z) z_j h_{i,n}(\alpha, \{z\}) . \]

By construction, \( h_{i,n}(\alpha, \{z\}) \) converges to \( f_i(\alpha, \{z\}) \) uniformly, as \( n \uparrow \infty \). In particular, if we define \( D_{i,j}(\alpha) \) as
\[ D_{i,j}(\alpha) = \alpha \sigma_{i,j} - \chi(\alpha) \sum_{z \in \mathbb{Z}^d} a(z) z_j f_i(\alpha, \{z\}) , \]

it is not difficult to show from the variational formula for the norm \( | \cdot |_\alpha \) that the second term on the right hand side of (5.8) also vanishes as \( n \uparrow \infty \), uniformly in \( \alpha \). This proves the first statement of the theorem.

Notice that \( D_{i,j}(\cdot) \) inherits the smoothness of \( f_i(\cdot, \{z\}) \).

It remains to check identity (5.2). By definition of the scalar product \( \langle \cdot, \cdot \rangle_\alpha \) and by identity (5.3), for any vector \( v \in \mathbb{R}^d \), the left hand side of (5.2) with the sequence \( -\chi(\alpha) f_{i,n}(\alpha, \eta) \) in place of \( h_{i,n}(\alpha, \eta) \), is equal to
\[ -\chi(\alpha)^2 < \sum_{j=1}^d v_j h_{j,n}(\alpha, \cdot), \sum_{j=1}^d v_j \mathfrak{Z}_a h_{j,n}(\alpha, \cdot) > . \]

Since \(-\mathfrak{Z}_a h_{j,n}\) converges to \( \mathfrak{w}_j \) in \( \mathfrak{F}_{-1} \), uniformly in \( \alpha \), and since \( h_{j,n} \) is \((n, \alpha)\)-uniformly bounded in \( \mathfrak{F}_1 \), the limit of the previous expression is equal to the limit of
\[ \chi(\alpha)^2 \sum_{j,k=1}^d v_j v_k \langle h_{j,n}(\alpha, \cdot), \mathfrak{w}_k \rangle = -\chi(\alpha)^2 \sum_{j,k=1}^d v_j v_k \sum_{z \in \mathbb{Z}^d} h_{j,n}(\alpha, \{z\}) z_k a(z) . \]

The last identity follows from the explicit formula for \( \mathfrak{w}_k \). Notice that a factor 1/2 appeared because in the definition of the inner product \( \langle \cdot, \cdot \rangle \), there is the term \((n+1)^{-1}\). By construction, \( h_{j,n}(\alpha, \{z\}) \) converges uniformly in \( \alpha \) to \( f_j(\alpha, \{z\}) \). In particular, the previous sum converges uniformly to
\[ -\chi(\alpha)^2 \sum_{j,k=1}^d v_j v_k \sum_{z \in \mathbb{Z}^d} f_j(\alpha, \{z\}) z_k a(z) . \]

By definition (5.9) of the diffusion coefficient \( D_{i,j}(\alpha) \), the previous expression is equal to
\[ \chi(\alpha) v \cdot \{ D(\alpha) - \alpha \sigma \} v . \]

This concludes the proof of the theorem. \( \blacksquare \)

We conclude this section with a technical lemma needed above.

**Lemma 5.2.** For each \( \varepsilon > 0 \) and \( k \geq 1 \), there exists \( \delta > 0 \) such that
\[ \sup_{|\alpha - \beta| \leq \delta} \| \mathfrak{Z}_a f_i(\alpha, \cdot) - \mathfrak{Z}_b f_i(\beta, \cdot) \|_{-1} \leq \varepsilon \]
and
\[ \sup_{|\alpha - \beta| \leq \delta} \lambda \sum_{n \geq 1} (1 + n)^k \sum_{A \in \mathcal{E}, n} \{ f_i(\alpha, A) - f_i(\beta, A) \}^2 \leq \varepsilon \]
for all \( 0 < \lambda < 1 \).
The proof of this lemma is implicit in the proof of the regularity of \( f_{\lambda}(.; A) \) presented in Theorem 5.1 and Lemma 5.2 of [10]. We just need to write the equation for \( f_{\lambda}(\alpha, \cdot) - f_{\lambda}(\beta, \cdot) \) as a resolvent equation with a right hand side which is a function in \( \mathbb{H}_{\lambda-1} \) times \( O(\alpha - \beta) \). Details are left to the reader.

6. Technical bounds

We present in this section some technical lemmas and some computations omitted in section 3.

6.1. Computation of \( N^2 L_N^* \psi_{t, t}^N / \psi_{t, t}^N \). Since \( L_N^* \) is the generator of the exclusion process associated to the transition probability \( p^*(y) = p(-y) \),

\[
\frac{N^2 L_N^* \psi_{t, t}^N(\eta)}{\psi_{t, t}^N(\eta)} = N^2 \sum_{x, y \in \Lambda^d_N} \eta(x)[1 - \eta(x + y)] p^*(y) \left( \frac{\psi_{t, t}^N(\sigma^{x, x+y} \eta)}{\psi_{t, t}^N(\eta)} - 1 \right).
\]

For each fixed bond \((x, y), \psi_{t, t}^N(\sigma^{x, x+y} \eta)/\psi_{t, t}^N(\eta)\) is an expression of order \( N^{-1} \) because \( \psi_{t, t}(\cdot, \eta) \) is a smooth function for each fixed configuration \( \eta \). We may therefore expand the exponential up to the second order. The order one term is exactly \( N^2 L_N^* \log \psi_{t, t}^N \) and is responsible for the first two lines of (4.3) plus a remainder of order \( N^{d-1} \). The second order term is equal to

\[
(1/2) \sum_{x, y \in \Lambda^d_N} \eta(x)[1 - \eta(x + y)] p^*(y) \left\{ \lambda(t, x + y/N) - \lambda(t, x/N) \right\}^2
- \sum_{i=1}^d \sum_{z \in \Lambda^d_N} (\partial_{u_i} \lambda)(t, z/N) \nabla_{x, x+y}(A_t f_i)(\eta^M(z), \tau_z \eta) \right\}^2.
\]

Since \( \ell + s_t + A \leq M \), the gradient \( \nabla_{x, x+y} \) acts either on the first coordinate or on the second but never on both. \( f_i(\cdot, \eta) \) being a smooth function, the contribution of the gradient \( \nabla_{x, x+y} \) applied on the first coordinate is at most of order \( M^{-d} \). Since there are \( O(M^{d-1}) \) boundary sites \( z \) for which \( \nabla_{x, x+y} \eta^M(z) \) does not vanish, the total contribution of the gradient \( \nabla_{x, x+y} \) acting on the first coordinate of \( A_t f_i \) is of order \( M^{-1} \).

We consider now the set of sites \( z \) for which the gradient \( \nabla_{x, x+y} \) acts on the second coordinate of \( A_t f_i \). In this case, \( z \) should be at a distance smaller than \( \ell + A \) from \( x \) and we may replace \( (\partial_{u_i} \lambda)(t, z/N) \) by \( (\partial_{u_i} \lambda)(t, x/N) \) paying a price of order \( \ell^{d+1} N^{-1} \). At this point, for a fixed \( i \), after a change of variables \( z' = z - x \), we may rewrite the sum appearing inside braces in the previous formula as

\[
(\partial_{u_i} \lambda)(t, x/N) \tau_x \nabla_{0,y} \sum_{z \in A_{\ell+A}} \frac{1}{|A_{\ell}|} \sum_{w \in A_{\ell}} f_i(\eta^M(z), \tau_z \eta).
\]

Since the summation over \( z \) takes place on \( A_{\ell+A} \), we may replace \( \eta^M(z) \) by \( \eta^M(0) \) paying a price of order \( \ell/M \). In this case the previous sum becomes

\[
(\partial_{u_i} \lambda)(t, x/N) \tau_x \nabla_{0,y} \sum_{z \in \mathbb{Z}^d} f_i(\eta^M(0), \tau_z \eta) = (\partial_{u_i} \lambda)(t, x/N) \tau_x \nabla_{0,y} \Gamma_{f_i(\eta^M(0), \cdot)}
\]

because the contribution of each fixed \( w \) is the same after replacing \( \eta^M(z) \) by \( \eta^M(0) \).

To obtain the third line of (4.3) and the correct order of the remainder, it remains to expand \( N\lambda(t, x + y/N) - \lambda(t, x/N) \) and to develop the square.
6.2. Replacement of $L^*(A_t f_1)(\eta^M(0), \eta)$ by $L^*_M(A_t f_1)(\eta^I(0), \eta)$. Observe initially that the generator acts either on the first coordinate or on the second but never on both because we assumed that $s_1 + \ell \leq M$. Hence, we have to show that the action of the generator on the first coordinate is negligible. This is the content of the next result.

Lemma 6.1. Fix a function $f$ in $\mathcal{F}$, a smooth function $G : \mathbb{R}_+ \times \mathbb{T}^d \rightarrow \mathbb{R}$ and assume that $M$ satisfies conditions (6.2). For every $T > 0$,

$$\lim_{\ell \to \infty} \limsup_{N \to \infty} \left| \int_0^T dt \int_{\mathbb{T}^d_N} G(t, z/N) \tau_z (L^* - L^*_M)(A_t f_1)(\eta^M(0), \eta) f^N_t dv^N_\alpha \right| = 0 .$$

Notice that in $L^*_M(A_t f_1)(\eta^M(0), \eta)$, the generator is acting only on the second coordinate because $\ell \leq M$.

Proof. Let $f_1(\alpha, \eta) = (\partial_\alpha f)(\alpha, \eta)$. Since $f(\alpha, \cdot)$ is a smooth function, the contribution of $(L^* - L^*_M)(A_t f_1)(\eta^M(0), \eta)$ is equal to

$$N^{1-d}M^{-d} \sum_{x \in \mathbb{T}^d} G(t, z/N) \tau_z \sum_{x \in \Lambda_M} \eta(x)(1 - \eta(x + y))p^*(y)(A_t f_1)(\eta^M(0), \eta) + o_N(1)$$

(6.1)

plus a similar term with a negative sign and $x + y$ in $\Lambda_M$, $x$ not in $\Lambda_M$. Here the remainder $o_N(1)$ is of order $N/M^{d+1}$. From this point, the proof is divided in several steps.

Step 1. The first one consists in translating the local functions $\eta(x)(1 - \eta(x + y))$, which lies at the boundary of $\Lambda_M$, by few steps in order to have their support contained in $\Lambda_M$. For this purpose, it is enough to show that for every fixed $y$,

$$N^{1-d}M^{-d} \sum_{x \in \mathbb{T}^d} G(t, z/N) \tau_z \sum_{x \in \Lambda_M} \tau_x W(A_t f_1)(\eta^M(0), \eta)$$

(6.2)

is negligible if $W = h - \tau_{\varepsilon_1} h$ for some local function $h$. Here and below, a function $H(t, \eta)$ is said to be negligible if

$$\lim_{\ell \to \infty} \limsup_{N \to \infty} \left| \int_0^T dt \int H_N(t, \eta) f^N_t dv^N_\alpha \right| = 0$$

for all $T > 0$. Since there exists a finite constant $C_0$ such that $H_N(\mu^N | \nu^N) \leq C_0 N^d$ for all measure $\mu^N$, by the entropy inequality, Feynman-Kac formula and the variational formula for the largest eigenvalue of a symmetric operator, to prove that a function is negligible, it is enough to show that

$$\lim_{\ell \to \infty} \limsup_{N \to \infty} \int_0^T dt \sup_f \left\{ \int H(t, \eta) f dv^N_\alpha - \varepsilon N^{2-d} D_N(f) \right\} \leq 0$$

(6.3)

for every $\varepsilon > 0$. Here, the supremum is carried over all densities $f$ and $D_N(f)$ is the Dirichlet form given by $D_N(f) = \langle -L_N \sqrt{f} , \sqrt{f} \rangle$, where $\langle \cdot, \cdot \rangle$ stands for the inner product in $L^2(\nu^N_\alpha)$.

Since the local function $W$ has mean zero with respect to all canonical invariant states, $W = L^*_\Lambda w$ for some finite set $\Lambda$ and some local function $w$, where $L^*_\Lambda$ stands
for the symmetric part of the generator $L$ restricted to the set $\Lambda$. In particular, we need only to show that

$$N^{1-d}M^{-d} \sum_{z \in \mathbb{T}_N^d} G(t, z/N) \tau_z \sum_{x \in \Lambda_M^{0}} \tau_x(\nabla_b w)(A\ell f_1)(\eta^M(0), \eta)$$

is negligible for a fixed bond $b = (b_1, b_2)$ and a fixed local function $w$. Fix $0 \leq t \leq T$, a density $f$ with respect to $\nu_0^N$ and consider the linear term in variational formula (6.1):

$$N^{1-d}M^{-d} \sum_{z \in \mathbb{T}_N^d} G(t, z/N) \sum_{x \in \Lambda_M^{0}} \int \tau_x(\nabla_b w)(A\ell f_1)(\eta^M(0), \eta) \tau_{-z}f \, d\nu_0^N,$$

where we performed a change of variables $\xi = \tau_z \eta$. Since $\tau_x \nabla_b = \nabla_{b+x} \tau_x$, performing a change of variables $\xi = \sigma^{b+z} \eta$, we may rewrite the previous expression as

$$N^{1-d}M^{-d} \sum_{z \in \mathbb{T}_N^d} G(t, z/N) \sum_{x \in \Lambda_M^{0}} \int \tau_x w(A\ell f_1)(\eta^M(0), \eta) \nabla_{b+\tau_z} f \, d\nu_0^N$$

plus a term of order $NM^{-1-d}$. This term appears when taking the difference $\nabla_{b+x}(A\ell f_1)(\eta^M(0), \eta)$ which is absolutely bounded by $CM^{-d}$.

Rewrite the difference $a - b = \tau_{-z}f(\sigma^b \eta) - \tau_{-z}f(\eta)$ as $(\sqrt{a} - \sqrt{b})(\sqrt{a} + \sqrt{b})$ and apply the elementary inequality $2ab \leq \gamma a^2 + \gamma^{-1}b^2$, which holds for every $\gamma > 0$ to estimate the previous expression by $Ce^{-1}M^{-2} + \varepsilon N^{2-d}D_N(f)$. This proves that (6.2) is negligible, concluding the first step.

**Step 2.** Once that all functions have been translated to have its support contained in $\Lambda_M$, we take advantage of the fact that each function which appears in (6.1) at one side of the boundary, appears also at the other side with reversed sign. In particular, adding the intermediary terms to complete a telescopic sum, after (6.2), (6.1) can be rewritten as

$$N^{1-d}M^{-d} \sum_{j=1}^m \sum_{z \in \mathbb{T}_N^d} G(t, z/N) \tau_z \sum_{x \in \Lambda_M^{0}} (\tau_x h_j)(\eta)(A\ell f_1)(\eta^M(0), \eta)$$

for a family of local functions $h_j = g_j - \tau_{-z}g_j$ for some $1 \leq i \leq d$. Here $m$ is a finite integer which depends on $p(\cdot)$ only. In particular, the local functions $h_j$ have mean zero with respect to all canonical invariant measures. Here again, $A$ is taken large enough for the support of each local function $\tau_x h_j$ to be contained in $\Lambda_M$.

We claim that such a term is negligible.

Since all local functions $h$ which have mean zero with respect to all canonical invariant measures can be expressed as $L_A^*h_0$ for some finite set $\Lambda$ and some local function $h_0$, fix a bond $b$, a local function $h_0$ and consider the linear term in (6.3):

$$N^{1-d}M^{-d} \sum_{z \in \mathbb{T}_N^d} G(t, z/N) \sum_{x \in \Lambda_M^{0}} \int \tau_x(\nabla_b h_0)(A\ell f_1)(\eta^M(0), \eta) \tau_{-z}f \, d\nu_0^N.$$
Since \( \tau_x \nabla_b = \nabla_{b+x} \tau_x \), a change of variables \( \xi = \sigma^{b+x} \eta \), similar to the one performed in the first part of the proof, permits to write the previous expression as

\[
\frac{N^{1-d}}{M^d} \sum_{z \in \mathbb{T}_N \setminus \Lambda} G(t, z/N) \sum_{x \in \Lambda_{M-A}} \int \tau_x h_0 (A_t f_1)(\eta^M(0), \sigma^{b+x} \eta) \nabla_{b+x} \tau_z f \, d\nu^N_{\alpha} \quad (6.4)
\]

\[
+ \frac{N^{1-d}}{M^d} \sum_{z \in \mathbb{T}_N \setminus \Lambda} G(t, z/N) \sum_{x \in \Lambda_{M-A}} \int \tau_x h_0 \nabla_{b+x} (A_t f_1)(\eta^M(0), \eta) \tau_z f \, d\nu^N_{\alpha}.
\]

We claim that both terms can be estimated by \( \varepsilon N^{2-d} D_N(f) \) and an expression which vanishes as \( N \uparrow \infty \) and then \( \ell \uparrow \infty \). Notice that in the second term, the gradient \( \nabla_{b+x} \) is acting only on the second coordinate.

Consider the first line of (6.4). Repeating the arguments presented at the end of the first step, we may bound this integral by the sum of \( \varepsilon N^{2-d} D_N(f) \) and

\[
\frac{C_\varepsilon^{-1}}{N^d M^d} \sum_{z \in \mathbb{T}_N \setminus \Lambda} \sum_{x \in \Lambda_{M-A}} \int (A_t f_1)(\eta^M(0), \sigma^{b+x} \eta)^2 \left\{ \tau_z \tilde{f}(\eta) + \tau_x f(\sigma^{b+x} \eta) \right\} \, d\nu^N_{\alpha}
\]

for some finite constant \( C \). Notice that we got an extra factor \( N^{-1} \) in this passage and that we included \( G \) and \( h_0 \) in the constant. We perform a change of variables \( \xi = \sigma^{b+x} \eta \) and denote by \( \tilde{f} \) the average of the translations of \( f \): \( \tilde{f} = N^{-d} \sum_{z \in \mathbb{T}_N} \tau_z f \) to rewrite the previous sum as

\[
C_\varepsilon^{-1} \int (A_t f_1)(\eta^M(0), \eta)^2 \tilde{f}(\eta) \, d\nu^N_{\alpha} \quad + \quad O(\ell^d M^{-d}).
\]

Here we took advantage of the fact that \( (A_t f_1)(\eta^M(0), \sigma^{b+x} \eta) = (A_t f_1)(\eta^M(0), \eta) \) unless \( x \) belongs to \( \Lambda_\ell \). Since \( f_1(\cdot, \eta) \) is a smooth function, uniformly in \( \eta \), the integral in the previous expression is less than or equal to

\[
C_\varepsilon^{-1} \int (A_t f_1)(\eta^M(0), \eta)^2 \tilde{f}(\eta) \, d\nu^N_{\alpha} \quad + \quad C_\varepsilon^{-1} \int \left\{ \eta^M(0) - \eta^0 \right\}^2 \tilde{f}(\eta) \, d\nu^N_{\alpha}.
\]

The usual proof of the two blocks estimate permits to show that the second integral can be estimated by \( \varepsilon N^{2-d} D_N(f) \) and an expression which vanishes as \( N \uparrow \infty \) and then \( \ell \uparrow \infty \). We leave the details to the reader. In contrast, the usual proof of the one block estimate permits to show that the limit, as \( N \uparrow \infty \), of the first integral minus \( \varepsilon N^{2-d} D_N(f) \) is bounded by

\[
C_\varepsilon^{-1} \sup_K \int \left\{ \frac{1}{|\Lambda_\ell - A|} \sum_{y \in \Lambda_{M-A}} \tau_y f_1(K/|\Lambda_\ell|, \eta) \right\}^2 \, d\mu_{\Lambda_\ell, K}.
\]

In this formula, \( \mu_{\Lambda_\ell, K} \) stands for the canonical measure on \( \Lambda_\ell \) concentrated on configurations with \( K \) particles and the supremum is carried over all integers \( 0 \leq K \leq |\Lambda_\ell| \). Divide the average in \( \Lambda_\ell \) in two averages and recall from Lemma A.7 in [R] that the Radon-Nikodym derivative \( d\mu_{\Lambda_\ell, K}/d\nu^N_{\Lambda_\ell, K} \) is bounded, uniformly in \( K \), provided \( \nu^N_{\beta} \) stands for the grand canonical measure on \( \Lambda_\ell \) with density \( \beta \). The previous expression is thus less than or equal to

\[
C_\varepsilon^{-1} \sup_{0 \leq \beta \leq 1} \int \left\{ \frac{1}{|\Lambda_\ell, 1|} \sum_{y \in \Lambda_{M, 1}} \tau_y f_1(\beta, \eta) \right\}^2 \, d\nu^N_{\beta}.
\]

In this formula, \( \Lambda_{\ell, 1} \) stands for one half of the cube \( \Lambda_\ell \). Since \( f_1(\alpha, \cdot) \) is local function, with uniform support and which has mean zero with respect to \( \nu^N_{\alpha} \), the
previous expression is of order $\ell^{-d}$ because $\nu_\alpha^N$ is a product measure. This conclude
the estimation of the first term in (6.5).

We turn now to the second term of (6.4). Notice that the gradient $\nabla_{b+x}(A_{\ell}\partial_1) (\eta^M(0), \eta)$ vanishes if $x$ does not belong to $\Lambda_{\ell+A}$. In particular,

$$
\sum_{x \in \Lambda_{\ell+A}} \tau_x h_0 \nabla_{b+x}(A_{\ell}\partial_1)(\eta^M(0), \eta) = \sum_{x \in \Lambda_{\ell+A}} \tau_x h_0 \nabla_{b+x}(A_{\ell}\partial_1)(\eta^M(0), \eta) \quad (6.5)
$$

is bounded by a constant which does not depend on $N$. On the other hand, for every $0 \leq K \leq |\Lambda_M|$, repeating the computation presented in the second paragraph
of the second step, from the end to the beginning, we obtain that

$$
\sum_{x \in \Lambda_{\ell+A}} \int \tau_x h_0 \nabla_{b+x}(A_{\ell}\partial_1)(\eta^M(0), \eta) \, d\mu_{\Lambda_M,K}
$$

$$
= \sum_{x \in \Lambda_{\ell+A}} \int (\tau_x \nabla_b) h_0 (A_{\ell}\partial_1)(\eta^M(0), \eta) \, d\mu_{\Lambda_M,K}.
$$

Summing over all bonds $b$, we recover $L^\ast h_0 = h - \tau_x g$, for some local function $g$ and some $1 \leq i \leq d$. The previous expression is thus equal to

$$
\sum_{x \in \partial^-_{\ell} \Lambda_{\ell+A}} \int (\tau_x g) (A_{\ell}\partial_1)(\eta^M(0), \eta) \, d\mu_{\Lambda_M,K}
$$

$$
- \sum_{x \in \partial^+_{\ell} \Lambda_{\ell+A}} \int (\tau_x g) (A_{\ell}\partial_1)(\eta^M(0), \eta) \, d\mu_{\Lambda_M,K},
$$

where $\partial^-_{\ell} \Lambda_{\ell+A}$ stands for the lower boundary in the $i$-th direction of $\Lambda_{\ell+A}$ and

$\partial^+_{\ell} \Lambda_{\ell+A}$ for the upper boundary. In particular, $x$ belongs to $\partial^+_{\ell} \Lambda_{\ell+A}$ if it belongs to $\Lambda_{\ell+A}$ and $x_i = \ell + A$. Since the measure $\mu_{\Lambda_M,K}$ is uniform,

$$
E_{\mu_{\Lambda_M,K}}[(\tau_x g) g'] = E_{\mu_{\Lambda_M,K}}[(\tau_y g) g']
$$

if the support of $\tau_x g$ and the one of $\tau_y g$ do not intersect the one of $g'$. Therefore, choosing $A$ large enough, the previous sum vanishes. This proves that the function

$$
(6.5)
$$

has mean zero with respect to all canonical invariant measures.

At this point, we follow the classical approach of nongradient systems (cf. 
24. Chapter 7) to estimate the second term of (6.4) using the standard Rayleigh-
Schroedinger perturbation theorem for the largest eigenvalue of a symmetric
operator. After a few steps we bound the difference of the second term of (6.4) with

$$
\varepsilon N^{d-1} B(f)
$$

by

$$
\frac{N^{2-d} \varepsilon}{M^d} \sup_{x \in \ell \in \mathbb{Z}_N^d} \int B f \, d\mu_{\Lambda_M,K} - \langle -L^\ast_{\Lambda_M} \sqrt{f}, \sqrt{f} \rangle_{\mu_{\Lambda_M,K}}
$$

In this formula, $B$ stands for the function $g$, the supremum is carried over all
integers $0 \leq K \leq |\Lambda_M|$ and $\langle \cdot, \cdot \rangle_{\mu_{\Lambda_M,K}}$ is the inner product in $L^2(\mu_{\Lambda_M,K})$. Since the spectral gap of the generator of the symmetric exclusion process in $\Lambda_M$ is of
order $M^2$ and $M^2 N^{-1}$ vanishes as $N \uparrow \infty$, by the perturbation theorem for
the largest eigenvalue of a symmetric operator, the previous expression is less than or
equal to

$$
\frac{C}{M^d \varepsilon^3} \sup_{K} \langle -L^\ast_{\Lambda_M} \rangle_{\mu_{\Lambda_M,K}} < \langle -L^\ast_{\Lambda_M} \rangle_{\mu_{\Lambda_M,K}}.
$$
Consider the linear term in the variational formula for the $H_{-1}$ norm of $B$. It is given by $2 \langle B, f \rangle_{\mu_{\Lambda M, K}}$ for some function $f \in L^2(\mu_{\Lambda M, K})$. Since $B$ has mean zero with respect to all canonical invariant measures, this is in fact a covariance that we estimate by $C_0(\ell)M^2 + C_1M^{-2} \langle f, f \rangle_{\mu_{\Lambda M, K}}$. By the spectral gap for the symmetric exclusion process, the second term is bounded by $\langle -L^*_{\Lambda M} f, f \rangle_{\mu_{\Lambda M, K}}$ if we choose $C_0$ sufficiently small. Therefore, $\langle -L^*_{\Lambda M} \rangle^{-1}B, B \rangle_{\mu_{\Lambda M, K}}$ is bounded by $C(\ell)M^2$. Since we are in dimension $d \geq 3$, the last displayed equation vanishes as $N \uparrow \infty$. This proves that the second term in (6.3) may be estimated by $\varepsilon N^{2-d}D_N(f)$ and an expression which vanishes as $N \uparrow \infty$. 

We have just proved that we may replace $L^*$ by $L^*_{\Lambda M}$ in (6.3). We show now that we can replace the average $\eta^M(0)$ by the average $\eta^\ell(0)$.

**Lemma 6.2.** Fix a function $\ell$ in $\mathcal{F}$, a smooth function $G : \mathbb{R}_+ \times \mathbb{T}^d \to \mathbb{R}$ and assume that $M$ satisfies the conditions (6.4). For every $T > 0$,

$$
\lim_{\ell \to \infty} \limsup_{N \to \infty} \int_0^T dt \int_{\mathbb{T}^d_N} \tau_z \left\{ L^*_{\Lambda M}(A_{\ell f})(\eta^M(0), \eta) - L^*_{\Lambda M}(A_{\ell f})(\eta^\ell(0), \eta) \right\} f^N_t \, d\nu^N_{\alpha} = 0.
$$

**Proof.** We have seen in the proof of the previous theorem that it is enough to show that

$$
\int_{\mathbb{T}^d_N} \tau_z \left\{ L^*_{\Lambda M}(A_{\ell f})(\eta^M(0), \eta) - L^*_{\Lambda M}(A_{\ell f})(\eta^\ell(0), \eta) \right\}
$$

is negligible.

Consider a class of function $B(\beta, \eta)$, $0 \leq \beta \leq 1$, whose support is contained in $\Lambda$. Repeating the well known steps of the proof of the one block estimate we obtain that

$$
\int B(\eta^M(0), \eta) f(\eta) \, d\nu^N_{\alpha} = \sum_{K=0}^{\lfloor\Lambda M\rfloor} \sum_{K=0}^{\lfloor\Lambda M\rfloor} C_K(f) \int B(K/|\Lambda M|, \eta) f_{M,K}(\eta) \, d\mu_{\Lambda M, K},
$$

where,

$$
C_K(f) = \int \{ \sum_{x \in \Lambda M} \eta(x) = K \} f \, d\nu^N_{\alpha}, \quad f_{M,K}(\eta) = \frac{f_M}{f_M(\eta)} \frac{\int f_M}{d\mu_{\Lambda M, K}}
$$

and $f_M$ is the conditional expectation $E_{\nu^N_{\alpha}}[f | \mathcal{F}_M]$. Here, for a set $\Lambda$, $\mathcal{F}_\Lambda$ stands for the $\sigma$-algebra generated by $\{\eta(z), z \in \Lambda\}$. At this point, $B(K/|\Lambda M|, \cdot)$ is a local function with support in $\Lambda$ and we repeat the procedure for $f_{M,K}, \mu_{\Lambda M, K}$ in place of $f$, $\nu^N_{\alpha}$. We obtain in this way that the previous sum is equal to

$$
\sum_{K=0}^{\lfloor\Lambda M\rfloor} C_K(f) \sum_{k=0}^{\lfloor\Lambda M\rfloor} C_k(f_{M,K}) \int B(K/|\Lambda M|, \eta) f_{M,K,\ell,k}(\eta) \, d\mu_{\Lambda M, k}
$$

with the obvious definitions for $C_k(f_{M,K}), f_{M,K,\ell,k}$.

Using that the Dirichlet form is convex, we may estimate

$$
\int N^{1-d} \sum_{z \in \mathbb{T}^d_N} G(t, z/N) B(\eta^M(0), \eta)(\tau_z f) \, d\nu^N_{\alpha} - \varepsilon N^{2-d}D_N(f)
$$

...
by
\[ N^{-d} \sum_{\tau \in \mathbb{T}_N^d} \sum_{K=0}^{\lfloor \Lambda_M \rfloor} C_K(f^\tau) \sum_{k=0}^{\lfloor \Lambda_k \rfloor} C_k(f_{M,K}) \tag{6.6} \]
\[ \left\{ G(t,z/N)N \int B(K/|\Lambda_M|,\eta)f_{M,K,f,k}(\eta) \, d\mu_{\Lambda,k} - \frac{\varepsilon N^2}{|\Lambda|} D_N(f_{M,K,f,k},\mu_{\Lambda,k}) \right\}. \]

In this formula, \( f^\tau = \tau_{-z} f \) and \( D_N(\cdot,\mu_{\Lambda,k}) \) is the Dirichlet form associated to the generator \( L^2_{\Lambda} \), and the reversible measure \( \mu_{\Lambda,k} \). Assume that \( B(K/|\Lambda_M|,\eta) \) has mean zero with respect to all invariant states \( \mu_{\Lambda,k} \), which is the case of the function we are considering in this lemma. By the Rayleigh-Schrödinger perturbation theorem for the largest eigenvalue of a symmetric operator, the expression inside braces in the previous formula is less than or equal to
\[ \frac{C|A_\varepsilon|}{\varepsilon} < (-L^2_{\Lambda})^{-1}B(K/|\Lambda_M|,\eta), B(K/|\Lambda_M|,\eta) > \mu_{\Lambda,k} \quad \tag{6.7} \]

We claim that in the particular case of this lemma, the previous expression is bounded by \( C\varepsilon^{-1}(K/|\Lambda_M| - k/|\Lambda|)^2 \). Indeed, let \( h \) be the local function \( f(K/|\Lambda_M|,\eta) - f(k/|\Lambda|,\eta) \). In the case where \( B \) is the function which appears in the statement of the lemma, the linear term of the variational formula for the \( H_{-1} \) norm is
\[ \frac{2}{|A_\varepsilon|} \sum_{y \in A_\varepsilon} \int (L^* \tau_y h) \, f \, d\mu_{\Lambda,k}, \]
where \( f \) is in \( L^2(\mu_{\Lambda,k}) \). Since \( L^* \tau_y h \) is a local function which has mean zero with respect to all invariant measures, we may localize \( f \) around \( y \), replace the scalar product by a covariance, use the spectral gap of the symmetric exclusion process, restricted to a cube whose length depend only on the support of \( h \), and apply Schwarz inequality to bound \( < (\nabla_h E[f|F_\Lambda])^2 > \) by \( < (\nabla_h f)^2 > \). At the end we obtain that the previous expression is less than or equal to
\[ \frac{C}{|A_\varepsilon|^2} \sum_{y \in A_\varepsilon} < (L^* \tau_y h)^2 >_{\mu_{\Lambda,k}} + < -L^* f, f >_{\mu_{\Lambda,k}}. \]

Since \( f(\cdot,\eta) \) is smooth, uniformly in \( \eta \), \( L^* \tau_y h \) is absolutely bounded by \( |K/|\Lambda_M| - k/|\Lambda|| \). This proves that \( \text{(6.7)} \) is bounded above by \( C\varepsilon^{-1}(K/|\Lambda_M| - k/|\Lambda|)^2 \).

Up to this point we proved that the expression inside braces in \( \text{(6.6)} \) is bounded above by \( C\varepsilon^{-1}(K/|\Lambda_M| - k/|\Lambda|)^2 \). Recalling the definition of the constants appearing in \( \text{(6.6)} \), we have that this sum is in fact
\[ \int \frac{C}{\varepsilon N^d} \sum_{z \in \mathbb{T}_N^d} \left\{ \eta^{M}(0) - \eta^{\ell}(0) \right\}^2 (\tau_{-z} f) \, d\nu_\alpha^N. \]

It remains to apply the two blocks estimate to conclude the proof. \( \square \)

6.3. Replacement of \( H_{i,j}(\eta) \) by \( \sigma_{i,j} F(\eta^i(0)) + J_{i,j}(\eta^i(0)) \). Fix a smooth function \( G : \mathbb{T}^d \times \mathbb{R} \to \mathbb{R} \) and two function \( f, g \) in \( \mathcal{F} \). Since the local functions \( f(\beta, \cdot) \) have a common finite support, for each fixed \( y \), there exists a finite integer \( A \) such that
\[ \nabla_{0,y} \Gamma G(\eta^{M}(0), \cdot) = \nabla_{0,y} \sum_{z \in \Lambda_A} f(\eta^M(0), \tau_z \eta) \].
Since $f(\cdot, \eta)$ are smooth functions, the difference between the previous expression and
\[
\nabla_{0,y} \sum_{z \in \Lambda_A} f(\eta^f(0), \tau_z \eta)
\]
is absolutely bounded by $C(A, f) |\eta^M(0) - \eta^f(0)|$, for some finite constant $C(A, f)$. By the two blocks estimate, the average over $T_N^d$ of this absolute value is negligible. After this replacement, the third line of (4.3) is seen to be composed of three different types of terms:
\[
\sum_{x \in T_N^d} G(t, x/N) \tau_x \sum_{y \in \mathbb{Z}^d} p^*(y) y_i y_j \eta(0)[1 - \eta(y)] , \\
\sum_{x \in T_N^d} G(t, x/N) \tau_x \sum_{y \in \mathbb{Z}^d} p^*(y) y_i \eta(0)[1 - \eta(y)] \Gamma^{A, \ell}_{y, \ell} (\eta) , \\
\sum_{x \in T_N^d} G(t, x/N) \tau_x \sum_{y \in \mathbb{Z}^d} p^*(y) \eta(0)[1 - \eta(y)] \Gamma^{A, \ell}_{y, \ell} (\eta) \Gamma^{A, \ell}_{x, \ell} (\eta) ,
\]
where, for some function $h$ in $\mathfrak{S}$,
\[
\Gamma^{A, \ell}_{y, \ell} (\eta) = \nabla_{0,y} \sum_{z \in \Lambda_A} h(\eta^f(0), \tau_z \eta) .
\]

By the one block estimate, the first sum can be replaced by
\[
\sum_{x \in T_N^d} G(t, x/N) \sigma_{i,j} F(\eta^f(x)) .
\]

We claim that the second sum is negligible because $\eta(0)[1 - \eta(y)] \Gamma^{A, \ell}_{y, \ell} (\eta)$ has mean zero with respect to all canonical invariant measures. Indeed, repeating the steps of the one block estimate, we are reduced to estimate
\[
\sup_K \int \eta(0)[1 - \eta(y)] \nabla_{0,y} \sum_{z \in \Lambda_A} f(K/|\Lambda_\ell|, \tau_z \eta) d\mu_{\Lambda_\ell, K} ,
\]
where the supremum is carried over all $0 \leq K \leq |\Lambda_\ell|$. A change of variables $\xi = \sigma^{0,y}_{\eta}$ permits to rewrite the previous expression as
\[
\sup_K \int \{\eta(y) - \eta(0)\} \sum_{z \in \Lambda_A} f(K/|\Lambda_\ell|, \tau_z \eta) d\mu_{\Lambda_\ell, K} .
\]
The integral vanishes for each fixed $K$ because $\mu_{\Lambda_\ell, K}$ is a uniform measure.

The third type of term requires some notation. For a function $h(\beta, \eta)$, smooth in the first coordinate and with a common finite support in the second, let
\[
\tilde{h}(\alpha, \beta) = E_{\nu, \beta}[h(\alpha, \eta)] .
\]
For $1 \leq i, j \leq d$ and $y$ in $\mathbb{Z}^d$, let
\[
h^{i,j}_y(\beta, \eta) = \eta(0)[1 - \eta(y)] \nabla_{0,y} \sum_{z \in \Lambda_A} f_i(\beta, \tau_z \eta) \nabla_{0,y} \sum_{z \in \Lambda_A} f_j(\beta, \tau_z \eta) .
\]
Notice that $h$ is smooth in the first coordinate and have a common finite support on the second coordinate. Moreover, an elementary computation shows that
\[
\sum_{y \in \mathbb{Z}^d} p^*(y) h^{i,j}_y(\beta, \eta) = 2 \sum_{x \in \mathbb{Z}^d} < f_i(\beta, \cdot), (-L^*) \tau_x f_j(\beta, \cdot) >_\beta .
\]
In this formula, $<\cdot,\cdot>_{\beta}$ stands for the inner product in $L^2(\nu_{\beta})$. Denote the right hand side by $J_{i,j}(\beta)$. Lemma 6.3 below shows that we may replace in (4.6) the third type of term by
\[
\sum_{x \in T_N^d} G(t, x/N) J_{i,j}(\eta^t(x)).
\]
Up to this point, we proved that the third line of (4.3) is equal to
\[
(1/2) \sum_{i,j=1}^d \sum_{x \in T_N^d} (\partial_{u_i} \lambda)(t, x/N)(\partial_{u_j} \lambda)(t, x/N) \left\{ \sigma_{i,j} F(\eta^t(x)) + J_{i,j}(\eta^t(x)) \right\}
\]
plus a term of order $o(N^d)$, where
\[
J_{n,i,j}(\beta) = 2 \sum_{x \in Z^d} <f_{i,n}(\beta, \cdot), (-L^s) \tau_x f_{j,n}(\beta, \cdot)>_{\beta}.
\]
Recall the definition of the function $J_{i,j}(\beta)$ given in (4.6). By Theorem 5.1 with the notation introduced in section 3, the previous sum is equal to
\[
(1/2) \sum_{i,j=1}^d \sum_{x \in T_N^d} (\partial_{u_i} \lambda)(t, x/N)(\partial_{u_j} \lambda)(t, x/N) \left\{ \sigma_{i,j} F(\eta^t(x)) + J_{i,j}(\eta^t(x)) \right\}
\]
plus a term of order $o(\ell N^d)$. To conclude this subsection, it remains to prove the next result.

**Lemma 6.3.** Fix a function $h(\beta, \eta)$ smooth in the first coordinate and with finite common support in the second. For positive integers $\ell$, $m$, let
\[
V^h_{\ell,m}(\eta) = \left| \frac{1}{|\Lambda_m|} \sum_{y \in \Lambda_m} h(\eta^t(0), \tau_y \eta) - h(\eta^t(0), \eta^t(0)) \right|.
\]
Then,
\[
\lim_{m \to \infty} \limsup_{\ell \to \infty} \sup_f \left\{ \int \frac{1}{N^d} \sum_{x \in T_N^d} \tau_x V^h_{\ell,m}(\eta) f d\nu^N_h - \varepsilon N^{2-d} D_N(f) \right\} = 0
\]
for all $\varepsilon > 0$.

**Proof.** Since $\nu_{\tau}$ is the Bernoulli product measure, for each $\beta$, an elementary computation shows that $(\partial_{\gamma}) h(\beta, \gamma) = \sum_{x \in \Lambda} h(\beta, \eta(x)) \gamma$, where $<\cdot,\cdot>_{\gamma}$ stands for the covariance with respect to $\nu_{\tau}$ and $\Lambda$ for a finite set which contains the common support of the function $h(\beta, \cdot)$. In particular, the derivative $(\partial_{\gamma}) h(\beta, \gamma)$ is uniformly bounded. Hence,
\[
\left| \tilde{h}(\eta^t(0), \eta^t(0)) - \tilde{h}(\eta^t(0), \eta^t(0)) \right| \leq C(\tilde{h}) \left| \eta^t(0) - \eta^t(0) \right|
\]
for some finite constant $C(\tilde{h})$. It follows from the two blocks estimate that we may replace $h(\eta^t(0), \eta^t(0))$ by $\tilde{h}(\eta^t(0), \eta^t(0))$ in the definition of $V^h_{\ell,m}$.

Following the classical proof of the one block estimate, we are reduced to estimate
\[
\sup_{K} \int \left| \frac{1}{|\Lambda_m|} \sum_{y \in \Lambda_m} h(\eta^t|\Lambda_\ell, \tau_y \eta) - h(\eta^t|\Lambda_\ell, \eta^t(0)) \right| d\mu_{\Lambda, K},
\]
where the supremum is carried over all $0 \leq K \leq |\Lambda_\ell|$. For each fixed $\ell$, denote by $K_\ell$ the integer which maximizes the previous variational formula. There exists
a subsequence \( \ell' \) such that \( K_{\ell'}/|\Lambda_{\ell'}| \) converges to some density \( \beta \) in \([0,1]\). In particular, the limsup, as \( \ell \uparrow \infty \), of the previous expression is less than or equal to

\[
\sup_{\beta \in [0,1]} \int \frac{1}{|\Lambda_m|} \sum_{y \in \Lambda_m} \hat{h}(\beta, \tau_y \eta) - \hat{h}(\beta, \eta^m(0)) \, d\nu_{\beta}
\]

because the finite marginals of the canonical measure converges to the grand canonical measures. Since \( \hat{h}(\beta, \cdot) \) is a smooth function,

\[
\hat{h}(\beta, \eta^m(0)) = \hat{h}(\beta, \beta) \pm C(\eta^m(0) - \beta) = E_{\nu_{\beta}}[\hat{h}(\beta, \eta)] \pm C(\eta^m(0) - \beta) .
\]

In particular, the previous variational formula is bounded above by

\[
\sup_{\beta \in [0,1]} \int \frac{1}{|\Lambda_m|} \sum_{y \in \Lambda_m} \hat{h}(\beta, \tau_y \eta) - E_{\nu_{\beta}}[\hat{h}(\beta, \eta)] \, d\nu_{\beta} + C \sup_{\beta \in [0,1]} \int |\eta^m(0) - \beta| \, d\nu_{\beta} .
\]

This expression vanishes as \( m \uparrow \infty \) because \( \nu_{\beta} \) is a product measure and \( \hat{h}(\beta, \cdot) \) are local functions with a finite common support. This concludes the proof of the lemma.

6.4. Estimation of the current. Fix \( i \leq h \leq d \) and recall the definition of \( V_i^\ell(\eta) \) given just after (4.5). Let

\[
A_{i,N,\ell,1}(t, \eta) = N^{1-d} \sum_{x \in T_N^d} (\partial u_i, \lambda)(t, x/N) \tau_x V_i^\ell(\eta) .
\]

By the nongradient estimates, for every \( T \geq 0 \),

\[
\lim_{\ell \to \infty} \limsup_{N \to \infty} \sup_{t \geq 0} \int_0^T \nu^N_{\alpha}(d\eta) f_i^N(\eta) A_{i,N,\ell,1}(t, \eta)
\]

\[
\leq C_0 \sup_{\alpha \in [0,1]} \left\| w_i^*(\alpha, \eta) \right\| + \sum_{1 \leq j \leq d} D_{i,j}(\alpha)[|\eta(e_j) - \eta(0)| - L^* f_i(\alpha, \eta)]_2^2
\]

for some finite constant \( C_0 \). Here \( \| \cdot \| \) is the norm introduced at the beginning of section 3. We refer to section 6 of [3] for the proof. Note that we don’t need in the present context the multiscale analysis of [3]. By Theorem 5.1 this expression vanishes if we replace \( f_i \) by \( f_{i,n} \) and let \( n \uparrow \infty \).
