Abstract

We present a symbolic algorithmic approach that allows to compute invariant manifolds and corresponding reduced systems for differential equations modeling biological networks which comprise chemical reaction networks for cellular biochemistry, and compartmental models for pharmacology, epidemiology and ecology. Multiple time scales of a given network are obtained by scaling, based on tropical geometry. Our reduction is mathematically justified within a singular perturbation setting using a recent result by Cardin and Teixeira. The existence of invariant manifolds is subject to hyperbolicity conditions, which we test algorithmically using Hurwitz criteria. We finally obtain a sequence of nested invariant manifolds and respective reduced systems on those manifolds. Our theoretical results are generally accompanied by rigorous algorithmic descriptions suitable for direct implementation based on existing off-the-shelf software systems, specifically symbolic computation libraries and Satisfiability Modulo Theories solvers. We present computational examples taken from the well-known BioModels database using our own prototypical implementations.

1. Introduction

Biological network models describing elements in interaction are used in many areas of biology and medicine. Chemical reaction networks are used as models of cellular biochemistry, including gene regulatory networks, metabolic networks and signaling networks. In epidemiology and ecology, compartmental models can be described as networks of interactions between compartments. Both in chemical reaction networks and in compartmental models the probability that two elements interact is assumed proportional to their abundances. This property, called mass action law in biochemistry, leads to polynomial differential equations in the kinetics.

For differential equations that describe the development of such networks over time a crucial question is concerned with reduction of dimension. We illustrate such a reduction and the steps involved for
the classical Michaelis–Menten system, an archetype of enzymatic reactions. The differential equations for the concentrations of relevant chemical species, which are substrate and enzyme-substrate complex, have the form

$$
y_1 = -\varepsilon k_1 y_1 + (k_1 y_1 + k_{-1})y_2
$$

$$
y_2 = \varepsilon k_1 y_1 - (k_1 y_1 + k_{-1} + k_2)y_2,
$$

involving a small parameter $\varepsilon$ that represents the ratio of the total concentration of the enzyme to the concentration of the substrate. The fact that this ratio is small is an assumption of the model that has to be verified in applications. In a first step toward reduction, a scaling transformation $y_1 = x_1$ and $y_2 = \varepsilon x_2$ yields

$$
x_1 = \varepsilon (-k_1 x_1 + (k_1 x_1 + k_{-1})x_2)
$$

$$
x_2 = k_1 x_1 - (k_1 x_1 + k_{-1} + k_2)x_2.
$$

In a second step, one uses singular perturbation theory to obtain the famous Michaelis–Menten equation. It consists of two components: First, we obtain a one dimensional invariant manifold given approximately by the quasi-steady state condition $k_1 x_1 - (k_1 x_1 + k_{-1} + k_2)x_2 = 0$. This considers the fast variable $x_2$ to be at the steady state and lowers dimension from two to one. Second, we obtain a reduced system for the slow variable:

$$
\dot{x}_1 = -\varepsilon \frac{k_1 k_2 x_1}{k_1 x_1 + k_{-1} + k_2}.
$$

With our example, we paraphrased the approach in a seminal paper by Heineken et al. [28], which was the first one to rigorously discuss quasi-steady state from the perspective of singular perturbation theory. Realistic network models may have many species and differential equations. Considerable effort has been put into model order reduction, i.e., finding approximate models with a smaller number of species and equations, where the reduced model can be more easily analyzed than the full model [46].

The scaling of parameters and variables by a small parameter $\varepsilon$ and the study of the limit $\varepsilon \to 0$ is central in singular perturbation theory. It is rather obvious that arbitrary scaling transformations are unlikely to provide useful information about a given system. Successful scalings, in contrast, are typically related to the existence of nontrivial invariant manifolds. Applications of scaling rely on the observation that, loosely speaking, any result that holds asymptotically for $\varepsilon \to 0$ remains valid for sufficiently small positive $\varepsilon$., provided some technical conditions are satisfied. To determine scalings of polynomial or rational vector fields that model biological networks, tropical equilibration methods were introduced and developed in a series of papers by Noel et al. [44], Radulescu et al. [47], Samal et al. [51, 50], and others. These methods open a feasible path for biological networks of high dimension. For a given system they provide a list of possible slow-fast systems, which may or may not yield invariant manifolds and reduced equations. Other methods due to Goeke et al. [26], and recently extended to multiple time scales by Kruff and Walcher [32], determine critical parameter values and manifolds for singular perturbation reductions.

The principal purpose of the present paper is to complement scaling with an algorithmic test for the existence of invariant manifolds and the computation of those manifolds along with corresponding reduced systems of differential equations. In the asymptotic limit, methods from singular perturbation theory, principally developed by Tikhonov [58] and Fenichel [21], are available. A recent extension to multiscale systems by Cardin and Teixeira [10] turns out to be a valuable tool for the systematic computation of reductions with nested invariant manifolds, and allows an algorithmic approach.

In the language of systems biology the situation at a given time scale can be described as follows: Faster variables have relaxed and satisfy quasi-steady state conditions, a subset of variables evolves toward quasi-steady state values, and all slower variables are constant. The sets of quasi-steady state conditions for relaxed variables define invariant manifolds, more precisely, they provide the lowest order approximations to the invariant manifolds. As the set of relaxed variables and thus quasi-steady state conditions increases, the respective invariant manifolds get nested so that later manifolds are contained
in earlier ones. Local linear approximations of these manifolds were proposed by Valorani and Paolucci [59] using numerical methods based on the local Jacobian. However, to the best of our knowledge, constructive approaches providing the nonlinear description of these manifolds and reduced models are still missing.

From a computer science point of view, we propose a novel symbolic computation-based algorithmic workflow for the reduction process outlined above. This includes in particular the automatic verification of certain hyperbolicity conditions required for the validity of the reductions. We restrict ourselves to the case of polynomial differential equations that covers mass action chemical reaction networks and compartmental models. We present a series of algorithms that takes as input a system of polynomial autonomous ordinary differential equations together with numerical information related to the desired coarse graining of the scaling. As output one finally obtains a collection of nested invariant manifolds for the input system, associated with smaller dimensional systems that govern the dynamics on those manifolds. This output establishes the reduced systems discussed above.

The computationally hard parts of our methods are reduced to decision problems in interpreted first-order logic over various theories. It turns out that quantifier alternation can be entirely avoided, so that the Satisfiability Modulo Theories (SMT) framework by Nieuwenhuis et al. [41] can be applied. Several corresponding SMT solvers are freely available and professionally supported [1, 12, 15, 17].

It is remarkable that we arrive with our comprehensive algorithmic work here at SMT sub-problems for several different logics, viz. linear integer arithmetic, linear real arithmetic, and non-linear real arithmetic. The algorithms presented here are suitable for straightforward implementation provided that a symbolic computation library, or computer algebra system, and an SMT solver are available. To ensure this, we have realized two independent prototypical realizations in software on our own, one in Python using freely available libraries, and one in Maple.

The plan of the paper is as follows: In Sect. 2.1 we introduce an abstract scaling procedure, which assumes, for given $0 < \varepsilon_\ast < 1$, the existence of families of exponents $c_{k,J}$ and $d_k$ for scaling polynomial coefficients and variables, respectively. From the scaled system, higher order terms are truncated, and the obtained system is partitioned into several time scales, ordered from fastest to slowest. A corresponding generic algorithm uses black-box functions $c$ and $d$. In Sect. 2.2 we make precise one possible way to realize $c$ and $d$, based on tropical geometry. So far, our transformations are mostly of formal nature. On these grounds, we algorithmically determine in Sect. 3 invariant manifolds and corresponding reduced systems, which makes the formal scaling meaningful in a mathematically precise way. In general, this is possible only for a certain number $\ell$ of time scales, where $\ell$ is explicitly found and—in contrast to existing alternative approaches—often larger than 2. Technically, we apply recent results by Cardin and Teixeira [10] based on Fenichel theory. In Sect. 4 we employ symbolic computation techniques, specifically Gröbner basis theory, to equivalently simplify our reduced systems, which are still scaled in terms of $\varepsilon_\ast$, $c$, and $d$. In Sect. 5 we finally transform back to the principal scale of the original system while preserving the obtained multiple time scales and the structure of the corresponding reduced systems. In particular, the various time scale factors remain explicit. Until here, the mathematical development of our framework has been accompanied by nine algorithms, and we give a tenth top-level algorithm and make precise how various modules are combined and interact with one another. In Sect. 6 we discuss various computational examples with software developed in the course of the present work. We consider models from the BioModels database, a repository of mathematical models of biological processes [34]. Our primary objective is to support the understanding of our algorithms, which naturally comes with a high ratio of negative examples, which do not have meaningful reductions. This is counter-balanced by a collection of biologically interesting positive examples in the Appendix A. In Sect. 7 we wrap up and point at possible future research directions.

2. Scaling of Polynomial Vector Fields

In what follows, we adopt a rather general scaling formalism that has been used recently in [43, 44, 46, 47, 51] and is generally rather recurrent in the literature on singular perturbations, see for instance Sect. 3. We use the convention that the natural numbers $\mathbb{N}$ include 0.
2.1. An Abstract Scaling Procedure

Our starting point is a parameter dependent system $S$ of polynomial differential equations

$$
y_k := \frac{dy_k}{dt} = \sum_{J} \gamma_{k,J} y^J,
$$

where the summation ranges over multi-indices $J = (j_1, \ldots, j_n) \in \mathbb{N}^n$, $\gamma_{k,J} \in \mathbb{R}$, and only finitely many $\gamma_{k,J}$ are non-zero. We abbreviate $y^J = y_1^{j_1} \cdots y_n^{j_n}$, as usual. In terms of network models, $y_k$ represents the concentration of either a chemical species or a type of individual in a compartment. Note that we use positive integers as indices, instead of concrete names for species and compartments. The real coefficients $\gamma_{k,J}$ describe actions of other species or individuals on the species or individual $k$. If these actions are activations one has $\gamma_{k,J} > 0$, whereas for repressions one has $\gamma_{k,J} < 0$. Several species may interact to produce an action on a given species $k$. This information is contained in the number of non-zero components of $J$. More precisely, the order of the action, defined as the number of species needed to produce that action, is the finite cardinality of the set $\{ i \in \{1, \ldots, n\} \mid j_i \neq 0 \}$. This terminology is inspired from chemical reactions, where the order represents essentially the number of reactant species.

Throughout this paper, we require that positive $y_k$ remain positive as time progresses. In other words, the positive first orthant $\mathcal{U} = (0, \infty)^n \subseteq \mathbb{R}^n$ is positively invariant for system (1), which is the case, e.g., in chemical reaction networks when $\gamma_{k,J} y^J \geq 0$ on all intersections of hyperplanes $\{ (y_1, \ldots, y_n) \in \mathbb{R}^n \mid y_k = 0 \}$ with $\mathcal{U}$.

We fix some small $\epsilon, \epsilon_* \in (0, 1)$, and we impose that $\gamma_{k,J} = \epsilon^{c_{k,J}} \gamma_{k,J}$,

$$
\gamma_{k,J} = \epsilon^{c_{k,J}} \gamma_{k,J},
$$

with rational numbers $c_{k,J}$. The tacit understanding is that only nonzero $\gamma_{k,J}$ are being considered. The intuitive idea is that the $\gamma_{k,J}$ are close to one. Moreover, we introduce a positive parameter $\epsilon$ and consider the system

$$
y_k = \sum_{J} \epsilon^{c_{k,J}} \gamma_{k,J} y^J,
$$

with $\epsilon$-dependent coefficients. Notice that (3) matches (1) at $\epsilon = \epsilon_*$. By renormalizing $y_k = \epsilon^{d_k} x_k$, $d_k \in \mathbb{Q}$, one obtains a system in scaled variables

$$
x_k = \sum_{J} \epsilon^{c_{k,J} + \langle D, J \rangle - d_k} \gamma_{k,J} x^J,
$$

with $D = (d_1, \ldots, d_n)$ and the dot product in $\mathbb{R}^n$ denoted by $\langle \cdot, \cdot \rangle$. This transformation preserves the positive invariance of $\mathcal{U}$. The scaling comes with the implicit assumption that for $i, j \in \{1, \ldots, n\}$, the relative order of $y_i$ with respect to $y_j$ is bounded by $y_i/y_j = \Theta(\epsilon^{d_i - d_j})$ for $\epsilon \to 0$, so that all $x_k$ get the same order of magnitude. Continuing, we set $\nu_k = \min \{ c_{k,J} + \langle D, J \rangle - d_k \mid \gamma_{k,J} \neq 0 \}$ to obtain

$$
x_k = \epsilon^{\nu_k} \sum_{J} \epsilon^{c_{k,J} + \langle D, J \rangle - d_k - \nu_k} \gamma_{k,J} x^J,
$$

where now all exponents of $\epsilon$ inside the sums are nonnegative. Finally one may perform a preliminary time scaling $\tau = \epsilon^{\mu} t$, $\mu = \min \{ \nu_1, \ldots, \nu_n \}$ to arrive at

$$
x_k' := \frac{dx_k}{d\tau} = \epsilon^{\nu_k - \mu} \sum_{J} \epsilon^{c_{k,J} + \langle D, J \rangle - d_k - \nu_k} \gamma_{k,J} x^J,
$$

with all exponents nonnegative. We are interested in system (5) for variable $\epsilon > 0$, in the asymptotic limit $\epsilon \to 0$.

We restructure (6) by collecting all variables with equal $\nu_k - \mu$ in vectors $z_1, \ldots, z_m$, where $z_k \in \mathbb{R}^{n_k}$ for $k \in \{1, \ldots, m\}$, in ascending order of exponents and such that $n_1 + \cdots + n_m = n$. We obtain a
system of the form

\[ z'_k = \varepsilon^{a_k} \tilde{f}_k(z, \varepsilon) = \varepsilon^{a_k} \left( \tilde{f}_k(z, 0) + \varepsilon^{d_k} p_{k,2} + \cdots + \varepsilon^{d_{k,w_k}} p_{k,w_k} \right) = \varepsilon^{a_k} \left( \tilde{f}_k(z, 0) + o(1) \right), \quad 1 \leq k \leq m, \]

where \( a_k, d_{k,j} \in \mathbb{Q}, 0 = a_1 < a_2 < \ldots < a_m, 0 < a'_{k,j}, \) and \( p_{k,j} \) are multivariate polynomials in \( z \) for \( 1 \leq k \leq m \) and \( 2 \leq j \leq w_k \). Note that the case \( m = 1 \) is not excluded. By substituting \( \delta := \varepsilon^{1/q} \), with a sufficiently large positive integer \( q \), one ensures that only nonnegative integer powers of \( \delta \) appear:

\[ z'_k = \delta^{b_k} \tilde{f}_k(z, \delta) = \delta^{b_k} \left( \tilde{f}_k(z, 0) + \delta^{b'_{k,2}} p_{k,2} + \cdots + \delta^{b'_{k,w_k}} p_{k,w_k} \right) = \delta^{b_k} \left( \tilde{f}_k(z, 0) + o(1) \right), \quad 1 \leq k \leq m, \]

where \( b_k, b'_{k,j} \in \mathbb{N}, 0 = b_1 < b_2 < \ldots < b_m, 0 < b'_{k,j} \) for \( 1 \leq k \leq m \) and \( 2 \leq j \leq w_k \).

Our idea is that the indices \( k \) correspond to different time scales \( \delta^b \tau \). For \( m > 1 \), system \( (8) \), as \( \delta \to 0 \), may be thought of as separating fast variables from increasingly slow ones. It will turn out in Sect. 3 that the exact number of time scales finally obtained by our overall approach can actually be smaller than \( m \).

Given certain conditions, which will be made explicit in Theorem 1 and with its application in Sect. 3.1, we may formally truncate the right hand sides of \( (8) \) and keep only terms of lowest order in \( \delta \):

\[ z'_k = \delta^{b_k} \tilde{f}_k(z, 0), \quad 1 \leq k \leq m. \]

In the sequel, we refer to the transformation process from \( (1) \) to \( (8) \) as \textit{scaling}. Strictly speaking, this comprises scaling in combination with \textit{partitioning}. We refer to the step from \( (8) \) to \( (9) \) as \textit{truncating}.

Algorithm 1 reflects our discussions so far. It takes as input a list \( S \) of differential equations representing system \( (1) \) and a choice of \( 0 < \varepsilon_* < 1 \) for \( (2) \). For our practical purposes, the polynomial coefficients in \( S \) as well as \( \varepsilon_* \) are taken from \( \mathbb{Q} \). Our algorithm is furthermore parameterized with a function \( c \) mapping suitable indices to rational numbers and a constant function \( d \) yielding either a tuple \( D = (d_1, \ldots, d_n) \) of rational numbers or \( \bot \). The black–box functions \( c \) and \( d \) reflect the mathematical assumptions around \( (2) \) and \( (4) \) that suitable \( c_{k,j} \) and \( d_k \) exist, respectively. Suitable instantiations for the parameters \( c \) and \( d \) can be realized, e.g., using tropical geometry, which will be the topic of Sect. 2.2.

It will turn out that instantiations of \( d \) can fail on the given combination of \( S \) and \( \varepsilon_* \), which is signaled by the return value \( \bot \) of \( d \), and checked right away in line 1 of Algorithm 1.

### 2.2. Scaling via Tropical Geometry

So far, the above transformations leading to \( (1) \) are a formal exercise. No particular strategy was applied for choosing \( \varepsilon_* \in (0,1) \). Early model reduction studies used dimensional analysis to obtain \( \varepsilon_* \) as a power product in model parameters [28, 53].

Here we discuss a different approach, based on tropical geometry [38, 41, 46, 57, 61, 50]. This approach starts with a slightly different interpretation of the scaling problem. In this interpretation, the value \( \varepsilon_* \) is not dictated by physico-chemistry, but it is freely chosen to provide “power” parametric descriptions of all the quantities occurring in the differential equations (parameters, monomials, time scales), in a similar way to describing curves by continuously varying real parameters. This interpretation is rooted in physics where it unravels scaling laws. It is also natural for any computation with orders of magnitude. In tropical geometry, it is encountered in several places: as Litvinov–Maslov dequantization of real numbers leading to degeneration of complex algebraic varieties into tropical varieties [37, 61], or in the theory of Puiseux series in relation to tropical varieties and pre-varieties [4].

The abstract scaling procedure leading to \( (6) \) is implemented with two additional requirements. Firstly, the orders \( c_{k,j} \) are not freely chosen, but are computed from \( \varepsilon_* \in (0,1) \) and \( \gamma_{k,j} \) as

\[ c_{k,j} = \frac{\text{round}(p \log_{\varepsilon_*} |\gamma_{k,j}|)}{p}. \]
Algorithm 1 ScaleAndTruncate

Input: 1. A list \( S = \left( \frac{d}{dt} = f_1, \ldots, \frac{d}{dt} = f_n \right) \) of autonomous first-order ordinary differential equations where \( f_1, \ldots, f_n \in \mathbb{Q}[y_1, \ldots, y_n] \);
2. \( c : \{1, \ldots, n\} \times \{1, \ldots, n\} \to \mathbb{Q} \);
3. \( d : \to \mathbb{Q}^n \cup \{ \perp \} \);
4. \( \varepsilon_* \in (0, 1) \cap \mathbb{Q} \)

Output: 1. A list \( (T_1, \ldots, T_m) \) where, abbreviating \( \frac{d}{dt} \) by a prime, \( T_k = (z'_k = \delta^b_k f_k) \) with \( z'_k \subseteq \{x'_1, \ldots, x'_n\} \), \( \bigcup_k z'_k = \{x'_1, \ldots, x'_n\} \), \( z'_1, \ldots, z'_m \) pairwise disjoint, \( b_1 < \ldots < b_m \in \mathbb{N} \), and \( f_k \subseteq \mathbb{Q}[x_1, \ldots, x_n] \), or the empty list;
2. A list \( (P_1, \ldots, P_m) \) of lists with \( P_k \subseteq \mathbb{Q}[x_1, \ldots, x_n][\delta] \) and \( |P_k| = |T_k| \) for \( k \in \{1, \ldots, m\} \);
3. A substitution \( \sigma \) for \( x_1, \ldots, x_n, \tau, \delta, \) and \( \varepsilon \).

The first output \( (T_1, \ldots, T_m) \) contains differential equations \( z'_k = \delta^b_k f_k(z, 0) \) for \( k \in \{1, \ldots, m\} \) in terms of system \( S \). The second output \( (P_1, \ldots, P_m) \) contains the higher order terms in \( S \) as polynomials \( p_k = \delta^b_k + b_k \cdot \tau p_k \) for \( \tau, \delta, \) and \( \varepsilon \).

This gives the following invariant: Denote \( \tilde{S} = \left( \bigcup_{k=1}^m T_k \oplus P_k \right) \sigma \), where \( (x' = g) \oplus p \) stands for \( x' = g + p \) and is applied elementwise. Then \( \tilde{S} \) is equal to \( S \) up to multiplication of the differential equation \( y_1 = \sum_{j} \gamma_j y^{y_j} \) in \( S \) with a positive scalar factor \( 1/\varepsilon_*^{x^{b_k}} \).

For \( q \in \mathbb{Q}[x_1, \ldots, x_n][\delta] \) we use \( \text{deg}_\delta(q) \) for the univariate degree of \( q \) in \( \delta \). Similarly, \( \text{tmon}_\delta(q) \) is the trailing monomial in \( \delta \).

1: if \( d() = \perp \) then
2: return \( () , () , () \)
3: end if
4: \( \mu := \infty \)
5: \( q := 1 \)
6: \( (d_1, \ldots, d_n) := d() \) \in \mathbb{Q}^n
7: for \( k := 1 \) to \( n \) do
8: \( h_k := 0 \)
9: for all monomials \( \gamma y^J \) in \( f_k \) do
10: \( \bar{\gamma} := \gamma / \varepsilon_*^{(k,J)} \)
11: \( \eta := c(k,J) + (\{d_1, \ldots, d_n\}, J) - d_k \)
12: \( \mu := \min(\mu, \eta) \)
13: \( q := \text{lcm}(q, \text{denom} \eta) \) \in \mathbb{N} \setminus \{0\}
14: \( h_k := h_k + \varepsilon^{\eta} \bar{\gamma} x^J \)
15: end for
16: end for
17: for \( k := 1 \) to \( n \) do
18: \( \bar{h}_k := h_k / \varepsilon^\mu \)
19: \( h_k := h_k [\varepsilon \leftrightarrow \delta^q] \) \in \mathbb{Q}[x_1, \ldots, x_n][\delta]
20: \( g_k := \text{tmon}_\delta h_k \)
21: \( p_k := h_k - g_k \)
22: end for
23: \( L := (\frac{d}{dt} = g_1, \ldots, \frac{d}{dt} = g_n) \)
24: \( (b_1, \ldots, b_m) := \text{sort}(\text{deg}_\delta g_1, \ldots, \text{deg}_\delta g_n) \), ascending and removing duplicates
25: for \( k := 1 \) to \( m \) do
26: \( T_k := (\frac{d}{dt} = g \in L | \text{deg}_\delta g = b_k) \)
27: \( P_k := \{ p_j \in \{p_1, \ldots, p_n\} | \text{deg}_\delta g_j = b_k \} \)
28: end for
29: \( \sigma := [x_1 \leftarrow y_1/\varepsilon^{d_1}, \ldots, x_n \leftarrow y_n/\varepsilon^{d_n}] \circ [\tau \leftarrow \varepsilon^\mu t] \circ [\delta \leftarrow \varepsilon^{1/\theta}] \circ [\varepsilon \leftarrow \varepsilon_*] \)
30: return \( (T_1, \ldots, T_m), (P_1, \ldots, P_m), \sigma \)
Algorithm 2 TropicalC
Input: 1. \( k \in \{1, \ldots, n\} \);
2. \( J \in \{1, \ldots, n\} \);
3. A list \( S = (y_1 = f_1, \ldots, y_n = f_n) \) of autonomous first-order ordinary differential equations where \( f_1, \ldots, f_n \in \mathbb{Q}[y_1, \ldots, y_n] \);
4. \( \varepsilon_* \in (0, 1) \cap \mathbb{Q} \);
5. \( p \in \mathbb{N} \setminus \{0\} \)
Output: \( c \in \mathbb{Q} \)
1: \( \gamma := \text{coeff}(f_k, y_J) \) \( \in \mathbb{Q} \)
2: \( c := \text{round}(p \log_{\varepsilon_*} |\gamma|)/p \) \( \in \mathbb{Q} \)
3: return \( c \)

Algorithm 3 TropicalD
Input: 1. A list \( S = (y_1 = f_1, \ldots, y_n = f_n) \) of autonomous first-order ordinary differential equations where \( f_1, \ldots, f_n \in \mathbb{Q}[y_1, \ldots, y_n] \);
2. \( \varepsilon_* \in (0, 1) \cap \mathbb{Q} \);
3. \( p \in \mathbb{N} \setminus \{0\} \)
Output: \( D \in \mathbb{Q}^n \cup \{\perp\} \)
1: \( \Pi(a_1, \ldots, a_n) := \text{TropicalEquilibration}(S, \varepsilon_*, p) \)
2: if not \( \mathbb{R} \models \exists a_1 \ldots \exists a_n \Pi \) then
3: return \( \perp \)
4: end if
5: \((d_1, \ldots, d_n) := \text{one possible choice for } a_1, \ldots, a_n \)
6: return \((d_1, \ldots, d_n) \)

Here, the rounding function rounds to nearest integer\(^1\). The positive integer \( p \) controls the precision of the rounding step.

Secondly, the orders \( D = (d_1, d_2, \ldots, d_n) \) satisfy certain constraints. These constraints result heuristically from the idea of compensation of dominant monomials [43]. Slow dynamics is possible if for each dominant, i.e., much larger than the other, monomial on the right hand side of (6), there is at least one other monomial of the same order, but with opposite sign. This condition, named tropical equilibration condition [43, 44, 46, 47, 51, 50], reads

\[
\min_{\gamma_k,J>0} (c_k,J + (D,J)) = \min_{\gamma_k,J<0} (c_k,J' + (D,J')).
\] (11)

On these grounds, given system \([1]\), the choice of \( \varepsilon_* \) boils down to defining orders of magnitude. Model parameters are coarse-grained and transformed to orders of magnitude in order to apply tropical scaling. The result depends on which parameters are close and which are very different as dictated by the coarse-graining procedure, i.e., by the choice of \( \varepsilon_* \). Decreasing \( \varepsilon_* \) destroys details and parameters tend to have the same order of magnitude. Increasing \( \varepsilon_* \) refines details and parameters range over several orders of magnitude. For instance, using \([10] \) and \( p = 1 \) parameters \( k_1 = 0.1 \) and \( k_2 = 0.01 \) have orders \( c_1 = 1 \) and \( c_2 = 2 \) for \( \varepsilon_* = 1/10 \), but \( c_1 = c_2 = 1 \) for \( \varepsilon_* = 1/50 \). This is the perspective taken in [43 44 51].

It is noteworthy that in the context of singular perturbation methods (cf. Sect. 3), which provide asymptotic results as a small parameter approaches zero, there are independent arguments for choosing \( \varepsilon_* \) rather small.

We are now ready to instantiate the black-box functions \( c \) and \( d \) in our generic Algorithm 1 with tropical versions as given in Algorithm 2 and Algorithm 3, respectively.

\(^1\)To be precise, we use the IEEE 754 rounding rule round to nearest, ties to even.
Algorithm 4 TropicalEquilibration

**Input:**
1. A list \( S = (y_1 = f_1, \ldots, y_n = f_n) \) of autonomous first-order ordinary differential equations where \( f_1, \ldots, f_n \in \mathbb{Q}[y_1, \ldots, y_n] \);
2. \( \varepsilon_* \in (0, 1) \cap \mathbb{Q} \);
3. \( p \in \mathbb{N} \setminus \{0\} \).

**Output:** A formula \( \Pi(a_1, \ldots, a_n) \) describing a finite union of convex polyhedra in \( \mathbb{R}^n \).

We use \( \langle \cdot, \cdot \rangle \) to denote the standard scalar product in \( \mathbb{Q}^{n+1} \).

1. \( A_0 := \{1, a_1, \ldots, a_n\} \in \mathbb{Q}[a_1, \ldots, a_n]^{n+1} \)
2. for \( j \) := 1 to \( n \) do
3. \( c := 0 \)
4. for all monomials \( \gamma y_1^{a_1} \cdots y_n^{a_n} \) in \( f_j \) do
5. \( a_0 := \text{round}(p \log_{\varepsilon_*} |\gamma|)/p \in \mathbb{Q} \)
6. \( c := c + 1 \)
7. \( \Sigma_c := \text{sgn} \gamma \in \{-1, 0, 1\} \)
8. \( A_c := (a_0, a_1, \ldots, a_n) \in \mathbb{Q} \times \mathbb{Z}^n \subseteq \mathbb{Q}^{n+1} \)
9. end for
10. \( B_j := \emptyset \)
11. for \( k := 1 \) to \( c \) do
12. for \( \ell := k + 1 \) to \( c \) do
13. if \( \Sigma_k \Sigma_\ell < 0 \) then
14. \( P := \{\langle A_k - A_\ell, A_0 \rangle = 0\} \)
15. for \( m := 1 \) to \( c \) do
16. \( \langle A_m - A_k, A_0 \rangle \geq 0 \)
17. end for
18. \( B_j := B_j \cup \{P\} \)
19. end if
20. end for
21. end for
22. end for
23. \( \Pi := \text{DisjunctiveNormalForm}(\bigwedge_{j=1}^{n} \bigvee_{p \in B_j} \bigwedge P) \)
24. return \( \Pi \)

Algorithm 2 explicitly uses, besides the parameters \( k \) and \( J \) specified for \( c \) in Algorithm 1 also the right hand sides of the input system \( \{1\} \) and the choice of \( \varepsilon_* \). As yet another parameter it takes the desired precision \( p \) for rounding in \( \{10\} \). Notice that the use of this extra information is compatible with the abstract scaling procedure in Section 2.1. Currying \( \{10\} \) allows to use Algorithm 2 in place of \( c \) in a formally clean manner.

Similarly, Algorithm 3 takes parameters \( \varepsilon_* \) and \( p \), while \( d \) is specified in Algorithm 1 to have no parameters at all. In \( \{11\} \) we use Algorithm 4 as a subalgorithm for tropical equilibration. One obtains a disjunctive normal form \( \Pi \), which explicitly describes a set \( \mathcal{P} = \{p \in \mathbb{Q}^n \mid \Pi(p)\} \) as a finite union of convex polyhedra, as known from tropical geometry. Every \( (d_1, \ldots, d_n) \in \mathcal{P} \) satisfies \( \{11\} \). The satisfiability condition in \( \{12\} \) tests whether \( \mathcal{P} \neq \emptyset \). We employ Satisfiability Modulo Theories (SMT) solving \( \{12\} \) using the logic QF_LRA \( \{2\} \) for quantifier-free linear real arithmetic. The set \( \mathcal{P} \) can get empty, e.g., when all monomials on the right hand side of some differential equation have the same sign. Such an exceptional situation is signaled with a return value \( \bot \) in \( \{13\} \). In the regular case \( \mathcal{P} \neq \emptyset \), the choice \( (d_1, \ldots, d_n) \) in \( \{15\} \) is provided by the SMT solver. From a practical point of view, the disjunctive normal form computation in Algorithm 4 is a possible bottleneck and requires good heuristic strategies \( \{39\} \).

With applications in the natural sciences one often wants to make in \( \{15\} \) an adequate choice for \( (d_1, \ldots, d_n) \) lying in a specific convex polyhedron \( \mathcal{P} \subseteq \mathcal{P} \), which technically corresponds to one conjunction in \( \Pi \). Such choices are subtle and typically require human interaction. For instance, when the chain of reduced dynamical systems ends with a steady state, it is interesting to consider the polyhedron \( \mathcal{P} \).
that is closest to that steady state. Such strategies are not implemented in the current version of our algorithm.

At this stage we have obtained a scaled system as defined in Sect. 2.1 including partitioning. The focus of the next section is to utilize this scaling for analytically substantiated reductions.

3. Singular Perturbation Methods

The theory of singular perturbations is used to compute and justify theoretically the limit of system \( \text{(8)} \) when \( \delta \rightarrow 0 \). There are several types of results in this theory. The results of Tikhonov, further improved by Hoppensteadt, show the convergence of the solution of system \( \text{(8)} \) to the solution of a differential-algebraic system in which the slow variables \( z_m \) follow differential equations and the remaining fast variables follow algebraic equations \( \text{(8s, 2a)} \). The results of Fenichel are known under the name of geometrical singular perturbations. He showed that the algebraic equations in Tikhonov’s theory define a slow invariant manifold that is persistent for \( \delta > 0 \) \( \text{[21]} \). For geometrical singular perturbations, differentiability in \( \delta \) is needed in system \( \text{(8)} \).

Samal et al. have noted that Tikhonov’s theorem is applicable to tropically scaled systems \( \text{[51]} \). For instance, with \( \delta_1 = \delta^\beta_2 \), system \( \text{(8)} \) may be rewritten as

\[
\begin{align*}
\dot{z}_1' &= \dot{g}_1(z, \delta_1), \\
\dot{z}_2' &= \delta_1 \dot{g}_2(z, \delta_1), \\
\vdots \\
\dot{z}_m' &= \delta_1 \dot{g}_m(z, \delta_1).
\end{align*}
\]

However, this approach comes with certain limitations. To start with, it allows only two time scales. Furthermore, in case \( b_2 > 1 \), there may be differentiability issues with respect to \( \delta_1 \), and some care has to be taken when one tries to apply to \( \text{(12)} \) also Fenichel’s results \( \text{[21]} \). In this section, we are going to generalize geometrical singular perturbations, and compute invariant manifolds and reduced models for more than two time scales, introducing further \( \delta_2, \ldots, \delta_\ell \). Our generalization is based on a recent paper by Cardin and Teixeira \( \text{[10]} \).

Section 3.1 presents relevant results from \( \text{[10]} \) adapted to our purposes here and applied to our system \( \text{(8)} \). In contrast to the original article, which is based on a series of hyperbolicity conditions, we introduce the stronger notion of hyperbolic attractivity. In Sect. 3.2 we describe efficient algorithmic tests for hyperbolic attractivity. Section 3.3 gives sufficient algorithmic criteria addressing the above-mentioned differentiability issues.

3.1. Application of a Fenichel Theory for Multiple Time Scales

From now on we consider our system \( \text{(8)} \) over the positive first orthant \( \mathcal{U} = (0, \infty)^n \subseteq \mathbb{R}^n \). A recent paper by Cardin and Teixeira \( \text{[10]} \) generalizes Fenichel’s theory to provide a solid foundation to obtain more than one nontrivial invariant manifold. This allows, in particular, the reduction of multi-time scale systems such as system \( \text{(8)} \). Technically, the approach considers a multi-parameter system using time scale factors \( \delta_1, \delta_1, \delta_2, \ldots \) instead of increasing powers of one single \( \delta \).

We let \( \ell \in \{2, \ldots, m \} \) and define

\[
\beta_1 = b_2 - b_1 = b_2, \quad \ldots, \quad \beta_{\ell-1} = b_\ell - b_{\ell-1},
\]

and furthermore \( \delta_1 = \delta^\beta_1, \ldots, \delta_{\ell-1} = \delta^\beta_{\ell-1}, \) and \( \bar{\delta} = (\delta_1, \ldots, \delta_{\ell-1}) \).

These definitions allow us to express also all \( \delta^{\beta_{k,j}} \) occurring in \( \text{(8)} \) as products of powers of \( \delta_1, \ldots, \delta_{\ell-1} \), with nonnegative but possibly non-integer rational exponents, via expressing each \( b_{k,j} \) as a nonnegative rational linear combination of \( \beta_1, \ldots, \beta_{\ell-1} \). This yields

\[
\begin{align*}
\dot{g}_k(z, \delta_1, \ldots, \delta_{\ell-1}) &= \dot{f}_k(z, \bar{\delta}), \quad 1 \leq k \leq m.
\end{align*}
\]

Moreover, we express \( \delta^{b_{k+1}} = \delta_1 \cdots \delta_{\ell-1} \cdot \eta_{k+1}, \ldots, \delta^{b_m} = \delta_1 \cdots \delta_{\ell-1} \cdot \eta_m \), via

\[
\begin{align*}
\eta_k(\delta_1, \ldots, \delta_{\ell-1}) &= \delta^{b_{k+1}} \delta_\ell, \quad \ell + 1 \leq k \leq m.
\end{align*}
\]
which is obtained by writing each \( b_k - b_\ell \) as a nonnegative rational linear combination of \( \beta_1, \ldots, \beta_{\ell-1} \). In these terms our system (8) translates to

\[
\begin{align*}
    z_1' &= \hat{g}_1(z, \delta) \\
    z_2' &= \delta_1 \hat{g}_2(z, \delta) \\
    &\vdots \\
    z_\ell' &= \delta_1 \cdots \delta_{\ell-1} \hat{g}_\ell(z, \delta) \\
    z_{\ell+1}' &= \delta_1 \cdots \delta_{\ell-1} \eta_{\ell+1}(\delta) \hat{g}_{\ell+1}(z, \delta) \\
    &\vdots \\
    z_m' &= \delta_1 \cdots \delta_{\ell-1} \eta_m(\delta) \hat{g}_m(z, \delta).
\end{align*}
\]

(16)

In terms of the right hand sides of (16) the application of relevant results in [10] requires that \( \hat{g}_1, \ldots, \hat{g}_\ell \) and \( \eta_{\ell+1} \hat{g}_{\ell+1}, \ldots, \eta_m \hat{g}_m \) are smooth on an open neighborhood of \( U \times [0, \vartheta_1) \times \cdots \times [0, \vartheta_{\ell-1}) \) with \( \vartheta_1 > 0, \ldots, \vartheta_{\ell-1} > 0 \). We are going to tacitly assume such smoothness here and address this issue from an algorithmic point of view in Sect. 3.3.

We are now ready to transform our system into \( \ell \) time scales as follows, where possibly \( \ell > 2 \):

\[
\begin{align*}
    \tau_1 &= \tau, \quad \tau_2 = \delta_1 \tau, \quad \ldots, \quad \tau_\ell = \delta_1 \cdots \delta_{\ell-1} \tau.
\end{align*}
\]

In time scale \( \tau_k \), with \( 1 \leq k \leq \ell \), system (16) then becomes

\[
\begin{align*}
    \delta_1 \cdots \delta_k - 1 \frac{dz_1}{d\tau_k} &= \hat{g}_1(z, \delta) \\
    &\vdots \\
    \delta_{k-1} \frac{dz_{k-1}}{d\tau_k} &= \hat{g}_{k-1}(z, \delta) \\
    \frac{dz_k}{d\tau_k} &= \hat{g}_k(z, \delta) \\
    \frac{dz_{k+1}}{d\tau_k} &= \delta_k \hat{g}_{k+1}(z, \delta) \\
    &\vdots \\
    \frac{dz_\ell}{d\tau_k} &= \delta_k \cdots \delta_{\ell-1} \hat{g}_\ell(z, \delta) \\
    \frac{dz_{\ell+1}}{d\tau_k} &= \delta_k \cdots \delta_{\ell-1} \eta_{\ell+1}(\delta) \hat{g}_{\ell+1}(z, \delta) \\
    &\vdots \\
    \frac{dz_m}{d\tau_k} &= \delta_k \cdots \delta_{\ell-1} \eta_m(\delta) \hat{g}_m(z, \delta).
\end{align*}
\]

(17)

For \( k = 1 \) and \( k = \ell \) we obtain empty products, which yield the neutral element 1, as usual.

Similarly to Sect. 2.1 we are interested in the asymptotic behavior for \( \delta \to 0 \), which is approximated by the elimination of higher order terms. We are now going to introduce a construction required for a justification of this approximation, which also clarifies the greatest possible choice for \( \ell \leq m \) above.

Define \( F_0 = 0 \) and

\[
Z_k = \begin{pmatrix} z_1 \\ \vdots \\ z_k \end{pmatrix}, \quad F_k(z, \delta) = \begin{pmatrix} \hat{f}_1(z, \delta) \\ \vdots \\ \hat{f}_k(z, \delta) \end{pmatrix}, \quad 1 \leq k \leq m.
\]
With system \( f_k \) in mind, we are going to use \( \hat{f}_k(z,0) \) in favor of \( g_k(z,0,\ldots,0) \). It is easy to see that both are equal. We define furthermore

\[
M_k = \{ F_k(z^*,0) = 0 \}, \quad M_k = \{ z^* \in U \mid F_k(z^*,0) = 0 \}, \quad 0 \leq k \leq m. \tag{18}
\]

The sets \( M_k \) are obtained from varieties defined by the lists \( M_k \) via intersection with the first orthant. Furthermore, \( U = M_0 \supseteq M_1 \supseteq \cdots \supseteq M_m \) establishes a chain of nested subvarieties, again intersected with the first orthant.

We say that \( M_1 \) is hyperbolically attractive on \( M_0 \), if \( M_1 \neq \emptyset \) and for all \( z \in M_1 \) all eigenvalues of the Jacobian \( D_z \hat{f}_1(z,0) \) have negative real parts. Therefore \( M_1 \) is a manifold. For \( k \in \{2, \ldots, m\} \), \( M_k \) is hyperbolically attractive on \( M_{k-1} \), if \( M_k \neq \emptyset \) and the following holds. Recall that using the defining polynomials \( F_{k-1} \) of \( M_{k-1} \), the implicit function theorem yields a unique local resolution of \( Z_{k-1} \) as functions of \( z_k, \ldots, z_m \), and thus we obtain

\[
\hat{f}_k(z,0) = \hat{f}_k(z_k, \ldots, z_m,0) \quad \text{on} \quad M_{k-1}.
\]

We now require that for all \( z \in M_k \) all eigenvalues of \( D_z \hat{f}_k(z_k, \ldots, z_m,0) \) have negative real parts. Again, \( M_k \) is a manifold. When \( M_k \) is hyperbolically attractive on \( M_{k-1} \) we write \( M_{k-1} \triangleright M_k \), where \( Z_k \) will be clear from the context.

If we find for some \( \ell \in \{1, \ldots, m\} \) that \( M_0 \triangleright M_1 \triangleright M_2 \triangleright \cdots \triangleright M_{\ell-1} \triangleright M_\ell \), then we simply write \( M_0 \triangleright \cdots \triangleright M_{\ell} \), and call this a hyperbolically attractive \( \ell \)-chain. Such a chain is called maximal if either \( \ell = m \) or \( M_{\ell} \not\triangleright M_{\ell+1} \).

Let \( M_0 \triangleright \cdots \triangleright M_{\ell} \) be a hyperbolically attractive \( \ell \)-chain. Consider for each \( k \in \{1, \ldots, \ell\} \) the following differential-algebraic system:

\[
0 = F_{k-1}(z,0), \quad \frac{dz_k}{d\tau} = \hat{f}_k(z,0), \quad \frac{dz_{k+1}}{d\tau} = 0, \quad \ldots, \quad \frac{dz_m}{d\tau} = 0. \tag{19}
\]

In the limiting case \( \delta = 0 \), this corresponds to system \( \hat{f}_k \). Recall that

\[
\tau_k = \delta_1 \cdots \delta_{k-1} \tau = \delta^{b_{k-b_1}} \cdots \delta^{b_{k-b_{k-1}}} = \delta^{b_k} \tau,
\]

and equivalently rewrite \( 19 \) as a triplet \( (M_{k-1}, T_k, R_k) \) with entries as follows:

\[
F_{k-1}(z,0) = 0, \quad \frac{dz_k}{d\tau} = \delta^{b_k} \hat{f}_k(z,0), \quad \frac{dz_{k+1}}{d\tau} = \cdots = \frac{dz_m}{d\tau} = 0. \tag{20}
\]

For a given index \( k \), we call \( (M_{k-1}, T_k, R_k) \) a reduced system on \( M_{k-1} \), where the relevant hyperbolic attractivity relation is \( M_{k-1} \triangleright M_k \). In order to indicate the relevance of \( M_0 \triangleright \cdots \triangleright M_{\ell} \) we write \( (M_0, T_1, R_1) \triangleright \cdots \triangleright (M_{\ell-1}, T_\ell, R_\ell) \) also for reduced systems, where \( M_{\ell} \) is not made explicit but relevant for the last triplet. Slightly abusing language, we speak of a hyperbolically attractive \( \ell \)-chain of reduced systems, which is maximal if \( M_0 \triangleright \cdots \triangleright M_{\ell} \) is.

The following theorem is a consequence of [10, Theorem A and Corollary A], specialized to the situation at hand.

**Theorem 1.** Let \( \ell \geq 2 \). Assume that \( (M_0, T_1, R_1) \triangleright \cdots \triangleright (M_{\ell-1}, T_\ell, R_\ell) \) is a hyperbolically attractive \( \ell \)-chain of reduced systems for system \( 16 \). Let \( K \subseteq U \) be compact. Then for sufficiently small \( \delta \) and all \( k \in \{1, \ldots, \ell\} \), system \( 16 \) admits invariant manifolds \( \mathcal{N}_{k-1} \) that depend on \( \delta \) and are \( (\delta_1 + \cdots + \delta_{k-1}) \)-close to \( M_{k-1} \cap K \) with respect to the Hausdorff distance. Moreover, there exists \( T > 0 \) such that solutions of system \( 16 \) on \( \mathcal{N}_{k-1} \) in time scale \( \tau_k \) converge to solutions of \( (M_{k-1}, T_k, R_k) \), uniformly on any closed subinterval of \( (0, T) \), as \( \delta \to 0 \).

For \( k \in \{1, \ldots, \ell\} \), the \( M_{k-1} \) are critical manifolds, which contain only stationary points. The systems \( (T_k, R_k) \) of ordinary differential equations on \( M_{k-1} \) approximate invariant manifolds \( \mathcal{N}_{k-1} \) in the sense of the theorem. They furthermore approximate solutions in time scale \( \tau_k \) of system \( 16 \), which is equivalent to our system \( 8 \). In other words, system \( 8 \) admits a succession of invariant manifolds,
Algorithm 5 ComputeReducedSystems

Input: Output of Algorithm 1
1. \((T_1, \ldots, T_m)\), a list of lists \(z_k = \delta^{b_k} f_k\);
2. \((P_1, \ldots, P_m)\), a list of lists of polynomials in \(\mathbb{Q}[x_1, \ldots, x_n][\delta]\);

We denote \(\xi_k := |T_k|, \Xi_k := \sum_{i=1}^{k} \xi_i\), and \(X = (x_1, \ldots, x_n)\).

Output: A list \(((M_0, T_1, R_1), \ldots, (M_{k-1}, T_{k-1}, R_{k-1}))\) of triplets where \(\ell \in \{2, \ldots, m\}\), or the empty list.

For \(k \in \{1, \ldots, \ell\}\), \(M_{k-1}\) is a list of real constraints defining \(M_{k-1} \subseteq \mathbb{R}^n\); \(T_k\) is a list of differential equations; \(R_k\) is a list of trivial differential equations \(x' = 0\) for all differential variables from \(T_{k+1}, \ldots, T_m\).

The triplets \((M_{k-1}, T_k, R_k)\) represent reduced systems according to (20).

1. \(U := (x_1 > 0, \ldots, x_n > 0)\)
2. \(M_0, Z, F, A := ()\)
3. for \(k := 1\) to \(m\) do
4. \(z := (x | x' = \delta^{b_k} g \in T_k)\)
5. \(f := (g | x' = \delta^{b_k} g \in T_k)\)
6. \(M_k := M_{k-1} \circ (f = 0)\)
7. \(\varphi, A := \text{IsHyperbolicallyAttractive}(U \circ M_k, Z, z, F, f, k, A)\)
8. if not \(\varphi\) then
9. break
10. end if
11. \(R_k := (x' = 0 | x' = h \in T_{k+1} \cup \cdots \cup T_m)\)
12. \(Z := Z \circ z\)
13. \(F := F \circ f\)
14. end for
15. if \# We either broke in line 2 preserving \(k\), or we have \(k = m + 1\) then
16. \(\ell := k - 1\)
17. if \(\ell < 2\) then
18. return ()
19. end if
20. if TestSmoothness((\(T_1, \ldots, T_m\)), (\(P_1, \ldots, P_m\)), \(\ell\)) = failed then
21. print "Warning: differentiability requires further verification"
22. end if
23. return ((\(M_0, T_1, R_1\)), \ldots, (\(M_{k-1}, T_{k-1}, R_{k-1}\)))

on which the behavior in the appropriate time scale is approximated by the respective reduced equations and, equivalently, (20). Note that only the \(\delta^{b_k} f_k(z,0)\) without the higher order terms enter the reduced systems \((M_{k-1}, T_k, R_k)\).

Algorithm 5 now starts with the output \((T_1, \ldots, T_m)\) of Algorithm 1 which represents the scaled system (19). Notice that each \(T_k\) already meets the specification in (20). In (11) we define \(U\) to contain defining inequalities of the first orthant \(U\). Starting with \(k = 1\), the for-loop in (12-14) successively constructs \(M_k\) and \(R_k\) such that in combination with \(T_k\) from the input, \((M_{k-1}, T_k, R_k)\) forms a reduced system as in (20). The loop stops when either \(k = m + 1\) or a test for hyperbolic attractivity in (17) finds that \(M_{k-1} \not\subseteq M_k\). We are going to discuss this test in detail in the next Sect. 3.2. Note that we maintain a matrix \(A\) for storing information between the subsequent calls of our test. In either case we arrive at a maximal hyperbolically attractive \((k - 1)\)-chain of reduced systems given as a list \((M_0, T_1, R_1), \ldots, (M_{k-2}, T_{k-1}, R_{k-1}))\). Following the notational convention used throughout this section we set \(\ell\) to \(k - 1\) in (16). The test in (17-19) reflects the choice of \(\ell\) in \(\{2, \ldots, m\}\) at the beginning of this section. Finally, (20) uses the second input \((P_1, \ldots, P_m)\) of the algorithm to address the smoothness requirements for system (16). We are going to discuss the corresponding procedure in detail in Sect. 3.3. It will turn out that this procedure provides only a sufficient test. Therefore we issue
Lemma 3. For $\Gamma = (\Delta, \ldots, \Delta_k)$, relevant eigenvalues without computing the systems with three time scales \[32\], we take in this section a linear algebra approach to obtain the $f$ to state hyperbolic attractivity

negative real parts.

Let $\Delta$ define $H = \begin{bmatrix} a_1 & a_3 & a_5 & \ldots & a_{2i-1} \\ a_0 & a_2 & a_4 & \ldots & a_{2i-2} \\ 0 & a_1 & a_3 & \ldots & a_{2i-3} \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ 0 & \ldots & \ldots & \ldots & a_i \end{bmatrix}$, $\Delta_j = |H_j|$.

Then all complex zeros of $f$ have negative real parts if and only if $\Delta_1 > 0, \ldots, \Delta_n > 0$. Notice that $\Delta_n = a_n \Delta_{n-1}$, and therefore $\Delta_n > 0$ can be equivalently replaced with $a_n > 0$.

We call $H$ the Hurwitz matrix and $\Delta_j$ the $j$-th Hurwitz determinant of $f$. Furthermore, we refer to $\Gamma = (\Delta_1 > 0 \wedge \cdots \wedge \Delta_{n-1} > 0 \wedge a_n > 0)$ as the Hurwitz conditions for $f$.

Our first result generalizes \[32\]: Proposition 1(ii)]. The proof is straightforward by induction.

**Lemma 3.** For $k \in \{1, \ldots, m\}$ define

$$J_k = \begin{pmatrix} 1 & \cdots & 0 \\ \vdots & \ddots & \vdots \\ 0 & \cdots & 1 \end{pmatrix} \cdot DZ_k F_k(z, 0) = \begin{pmatrix} D_{z_1} \hat{f}_1(z, 0) & \cdots & D_{z_k} \hat{f}_1(z, 0) \\ \vdots & \ddots & \vdots \\ D_{z_1} \hat{f}_2(z, 0) & \cdots & D_{z_k} \hat{f}_2(z, 0) \\ \vdots & \ddots & \vdots \\ D_{z_1} \hat{f}_k(z, 0) & \cdots & D_{z_k} \hat{f}_k(z, 0) \end{pmatrix}.$$  

Let $\ell \in \{1, \ldots, m\}$. Then $\mathcal{M}_0 > \cdots > \mathcal{M}_\ell \mathcal{M}_0 \neq \emptyset$ if and only if $\mathcal{M}_\ell \neq \emptyset$ and for all $k \in \{1, \ldots, \ell\}$, all sufficiently small $\delta_1^0 > 0, \ldots, \delta_{k-1}^0 > 0$, and all $z^* \in \mathcal{M}_k$, all eigenvalues of $J_k(\delta_1^0, \ldots, \delta_{k-1}^0, z^*)$ have negative real parts.

In particular, one can choose $\delta_1^0 = \cdots = \delta_{k-1}^0 = \delta^* \lozenge$ with sufficiently small $\delta^*$ and consider $J_k^* = \text{diag}(1, \ldots, \delta^*) \cdot DZ_k F_k(z, 0)$.  

Let $\Gamma_k$ denote the Hurwitz conditions for the characteristic polynomial of $J_k^*$. Then Lemma 3 allows to state hyperbolic attractivity $\mathcal{M}_0 \supset \cdots \supset \mathcal{M}_\ell$ as a first-order formula over the reals as follows:

$$\left( \exists (0 < z) : F_k(z, 0) = 0 \right) \wedge \left( \bigwedge_{k=1}^\ell \exists (0 < z^*) \forall (0 < \sigma) \forall (0 < z) : F_k(z, 0) = 0 \Rightarrow \Gamma_k(\sigma, z) \right).$$  

(21)
On these grounds, any real decision procedure [57, 13, 63] provides an effective test for hyperbolic attractivity. However, our formulation [21] uses a quantifier alternation \( \exists \sigma \forall q \) in its second part. From a theoretical point of view, such a bounded alternation does not affect the asymptotic worst-case complexity, which remains single exponential [27]. From a practical point of view, we would like to continue using SMT solving over a quantifier-free logic. Our next result allows a suitable first-order formulation without quantifier alternation. Its proof combines [32, Lemma 3] with our Lemma 3.

**Proposition 4** (Effective Characterization of Hyperbolically Attractive \( \ell \)-Chains). Define \( A_1 = D_{z_1} f_1(z, 0) \). For \( k \in \{ 2, \ldots, m \} \) define

\[
\begin{pmatrix}
A_{k-1} & B_k \\
C_k & V_k
\end{pmatrix} =
\begin{pmatrix}
D_{z_k} f_{k-1}(z, 0) & D_{z_k} \hat{f}_{k-1}(z, 0) \\
D_{z_k} f_k(z, 0) & D_{z_k} \hat{f}_k(z, 0)
\end{pmatrix},
\]

and note that \( \begin{pmatrix} A_{k-1} & B_k \\ C_k & V_k \end{pmatrix} = A_k \). Let \( \ell \in \{ 1, \ldots, m \} \). Then \( M_0 \triangleright \cdots \triangleright M_\ell \) if and only if

(i) \( M_\ell \neq \emptyset \),

(ii) for all \( z^* \in M_1 \) all eigenvalues of \( W_1(z^*) \), where \( W_1 = A_1 \), have negative real parts,

(iii) for all \( k \in \{ 2, \ldots, \ell \} \) and all \( z^* \in M_k \), \( A_{k-1}(z^*) \) is regular and all eigenvalues of \( W_k(z^*) \), where \( W_k = V_k - C_k A_{k-1}^{-1} B_k \), have negative real parts.

**Proof.** Assume \( M_0 \triangleright \cdots \triangleright M_\ell \). By Lemma 3 we have \( M_\ell \neq \emptyset \). For all \( z^* \in M_1 \), all eigenvalues of the Jacobian \( W_1(z^*) \) have negative real parts by the definition of hyperbolic attractivity. Let now \( k \in \{ 2, \ldots, \ell \} \), \( z^* \in M_k \), and define \( P = \text{diag}(1, \ldots, g^{k-2}) \). Using Lemma 3 we fix \( 0 < \tau^* < 1 \) such that for all \( 0 < g^* < \tau^* \) all eigenvalues of \( J_k'_{g^*}(z^*) = P(g^*) A_{k-1}(z^*) \) have negative real parts. It follows that \( P(g^*) A_{k-1}(z^*) \) and \( A_{k-1}(z^*) \) are all regular. Next, consider

\[
J_k' = \begin{pmatrix} P A_{k-1} & P B_k \\ g^{k-1} C_k & g^{k-1} V_k \end{pmatrix}.
\]

Using Lemma 3 once more, we find \( 0 < \sigma^* < \tau^* \) such that for all \( 0 < g^* < \sigma^* \) also all eigenvalues of \( J_k'_{g^*}(z^*) \) have negative real parts. Now \( J_k'_{g^*}(z^*) \) satisfies condition (ii) of [32] Lemma 3] with \( \delta = \sigma^* \) and \( \varepsilon = (g^*)^{k-1} \), which allows us to conclude that all eigenvalues of \( (V_k - C_k (P A_{k-1})^{-1} P B_k) (g^*, z^*) = (V_k - C_k A_{k-1}^{-1} P^{-1} P B_k) (g^*, z^*) = W_k(z^*) \) have negative real parts as well.

Assume, vice versa, that (i)-(iii) hold. We use induction on \( k \) to show \( M_0 \triangleright \cdots \triangleright M_k \) for \( 1 \leq k \leq \ell \). For \( k = 1 \) we have \( M_0 \triangleright M_1 \) by definition of hyperbolic attractivity. Assume that \( 2 \leq k \leq \ell \) and \( M_0 \triangleright \cdots \triangleright M_{k-1} \). By Lemma 3 there exists \( 0 < \tau^* \) such that for all \( 0 < \sigma^* < \tau^* \) and all \( z^* \in M_{k-1} \) all eigenvalues of \( P(\sigma^*) A_{k-1}(z^*) \) have negative real parts, where \( P = \text{diag}(1, \ldots, (\sigma^*)^{k-2}) \). We rewrite \( W_k = V_k - C_k (P A_{k-1})^{-1} P B_k \). Then \( W_k(z^*) \) satisfies condition (i) of [32] Lemma 3] with \( A = P(\sigma^*) A_{k-1}(z^*) \), \( B = P(\sigma^*) B_k(z^*) \), \( C = C_k(z^*) \) and \( D = V_k(z^*) \). Thus there exists \( 0 < \delta \) such that for all \( 0 < \varepsilon < \delta \) all eigenvalues of

\[
\left( \begin{array}{cc}
P(\sigma^*) A_{k-1}(z^*) & P(\sigma^*) B_k(z^*) \\ \varepsilon C_k(z^*) & \varepsilon V_k(z^*)
\end{array} \right)
\]

have negative real parts. Choosing \( g^* = \min \{ \sigma^*, k^{-\sqrt{\varepsilon}} \} \) in Lemma 3 yields \( M_0 \triangleright \cdots \triangleright M_k \). \( \square \)

From now on let \( \Gamma_k \) denote the Hurwitz conditions for the characteristic polynomial of \( W_k \), which—in contrast to the ones used in [21]—do not depend on \( g \) anymore.

**Corollary 5** (Logic-Based Test for Hyperbolically Attractive \( \ell \)-Chains). For \( k \in \{ 1, \ldots, m \} \) define

\[
\varphi_k = \left( \exists (0 < z) : F_k(z, 0) = 0 \right),
\psi_k = \left( \forall (0 < z) : F_k(z, 0) = 0 \rightarrow \Gamma_k(z) \right).
\]

Let \( \ell \in \{ 1, \ldots, m \} \). Then \( M_0 \triangleright \cdots \triangleright M_\ell \) if and only if \( \mathbb{R} \models \varphi_\ell \land \bigwedge_{k=1}^{\ell} \psi_k \).
Proof. Assume $M_0 \triangleright \cdots \triangleright M_\ell$. Then Proposition 4 yields its conditions (i)–(iii). Now, $\varphi_\ell$ holds as a formalization of (i). Furthermore, $\psi_1$ holds as a formalization of (ii), and the validity of $\psi_2, \ldots, \psi_\ell$ follows directly from (iii). Hence $\mathbb{R} \models \varphi_\ell \land \bigwedge_{k=1}^\ell \psi_k$.

Assume, vice versa, that $\mathbb{R} \models \varphi_\ell \land \bigwedge_{k=1}^\ell \psi_k$. We show $M_0 \triangleright \cdots \triangleright M_\ell$ by induction on $\ell$. If $\ell = 1$, then $\varphi_1$ formalizes (i) and $\psi_1$ formalizes (ii) in Proposition 4, and we obtain $M_0 \triangleright M_1$. Let now $\ell > 1$. Then $\varphi_\ell$ formalizes Proposition 4(i). Our induction hypothesis yields $M_0 \triangleright \cdots \triangleright M_{\ell-1}$. By Lemma 3 there exists $0 < \tau^*$ such that for all $0 < \sigma^* < \tau^*$ and all $z^* \in M_{\ell-1} \supseteq M_\ell$ all eigenvalues of $P(\sigma^*)A_{\ell-1}(z^*)$, where $P = \text{diag}(1, \ldots, (\sigma^*)^{\ell-2})$, have negative real parts. In particular, $P(\sigma^*)A_{\ell-1}(z^*)$ is regular and so is $A_{\ell-1}(z^*)$. Furthermore, the Hurwitz conditions in $\psi_1$ guarantee for all $z^* \in M_\ell$ that $W_\ell(z^*)$ has only negative eigenvalues. Taking these observations together, Proposition 4(iii) is satisfied, hence $M_0 \triangleright \cdots \triangleright M_\ell$.

In contrast to [21], our first-order characterization
\[
\left( \exists (0 < z) : F_\ell(z, 0) = 0 \right) \land \left( \bigwedge_{k=1}^\ell \forall (0 < z) : F_k(z, 0) = 0 \Rightarrow \Gamma_k(z) \right)
\]  
(22)
in Corollary 5 has no quantifier alternation. Note that the two top-level components of (22) establish two independent decision problems, addressing non-emptiness of the manifold and our requirement on the eigenvalues, respectively.

It is easy to see that for all $\ell \in \{1, \ldots, m\}$ and all $k \in \{1, \ldots, \ell-1\}$, $\varphi_\ell$ entails $\varphi_k$. Thus (22) can be equivalently rewritten as $\bigwedge_{k=1}^\ell (\varphi_k \land \psi_k)$, explicitly:
\[
\bigwedge_{k=1}^\ell \left( \exists (0 < z) : F_k(z, 0) = 0 \land \forall (0 < z) : F_k(z, 0) = 0 \Rightarrow \Gamma_k(z) \right).
\]  
(23)
Our approach tests the conjunction in (23) using a for-loop over $k$ in Algorithm 5. Technically, this construction ensures with the test for $\mathcal{M}_{k-1} \triangleright \mathcal{M}_k$ in Algorithm 6 that $\mathcal{M}_0 \triangleright \cdots \triangleright \mathcal{M}_{k-1}$ already holds, and exploits the fact that $\psi_k$ and $\varphi_k$ do not refer to smaller indices than $k$.

In l.15 we test the validity of $\varphi_k$. Using from the input the defining inequalities and equations $M = \{ \mathcal{M}_k \}$ of $\mathcal{M}_k$ along with $Z = Z_{k-1}$, $z = z_k$, $F = F_{k-1}$, $f = f_k$, and $A = A_{k-1}$, we construct in l.14 $\mathcal{A}' = A_k$ as noted in Proposition 4. In l.14 we construct the Hurwitz conditions $\Gamma = \Gamma_k$ according to Theorem 2. On the grounds of the validity of $\varphi_k$ tested in l.14, we finally test in l.20 the validity of $\psi_k$ and return a corresponding Boolean value. We additionally return $\mathcal{A}' = A_k$ for reuse with the next iteration. The validity tests for $\varphi_k$ and $\psi_k$ in l.14 and l.20 respectively, amount to SMT solving, this time using the logic QF_NRA [2] for quantifier-free nonlinear real arithmetic. Recall the positive integer parameter $p$ used for the precision with both Algorithm 2 and Algorithm 3. For $p > 1$ symbolic computation possibly yields fractional powers of numbers in the defining equations for manifolds as well as in the vector fields of the differential equations. However, such expressions are not covered by QF_NRA. When this happens, we catch the corresponding error from the SMT solver and restart with floats.

### 3.3. Sufficient Smoothness Criteria

Let us get back to the requirement in Sect. 3.1 that $\tilde{g}_1$, ..., $\tilde{g}_k$ and $\eta_{\ell+1} \tilde{g}_{\ell+1}$, ..., $\eta_m \tilde{g}_m$ occurring on the right hand sides of system (16) are all smooth on an open neighborhood of $U \times [0, \tilde{v}_1) \times \cdots \times [0, \tilde{v}_{r-1}]$ with $\tilde{v}_1 > 0$, ..., $\tilde{v}_{r-1} > 0$. An obvious criterion for smoothness is that all those expressions are polynomials in $z$ and $\delta$.

Recall the definitions of $\tilde{g}_k$ for $k \in \{1, \ldots, m\}$ in (14) and of $\eta_k$ for $k \in \{\ell + 1, \ldots, m\}$ in (15). For $k \in \{1, \ldots, m\}$ and $j \in \{1, \ldots, w_k\}$ one finds nonnegative $r_1$, ..., $r_{\ell-1} \in \mathbb{Q}$ such that

$$((\beta_1, \ldots, \beta_{\ell-1}), (r_1, \ldots, r_{\ell-1})) = b_{k,j},$$

and for $k \in \{\ell + 1, \ldots, m\}$ one finds nonnegative $r_1$, ..., $r_{\ell-1} \in \mathbb{Q}$ such that

$$((\beta_1, \ldots, \beta_{\ell-1}), (r_1, \ldots, r_{\ell-1})) = b_k - b_{\ell}.$$

Such representations always exist but are not unique in general. If one even finds suitable nonnegative integers $r_1$, ..., $r_{\ell-1} \in \mathbb{N}$, which do not always exist, then one obtains $\tilde{g}_1$, ..., $\tilde{g}_m$ as polynomials in $z$ and $\delta$, and $\eta_{\ell+1}$, ..., $\eta_m$ as polynomials in $\delta$, which is sufficient for our criterion above.

An improved but still only sufficient criterion uses similar constructions to directly verify the existence of polynomial representations of the products $\eta_{\ell+1} \tilde{g}_{\ell+1}$, ..., $\eta_m \tilde{g}_m$ in contrast to considering the factors independently. From an algorithmic point of view, we furthermore have to take into account that $P_1$, ..., $P_m$ obtained in Algorithm 1 do not contain $b_{k,j}$ but $b_k + b_{k,j}$. For $k \in \{1, \ldots, \ell\}$ and $j \in \{1, \ldots, w_k\}$ we try to find $r_1$, ..., $r_{\ell-1} \in \mathbb{N}$ such that

$$((\beta_1, \ldots, \beta_{\ell-1}), (r_1, \ldots, r_{\ell-1})) = b_{k,j} = (b_k + b_{k,j}) - b_k > 0,$$

and for $k \in \{\ell + 1, \ldots, m\}$ we try to find $r_1$, ..., $r_{\ell-1} \in \mathbb{N}$ such that

$$((\beta_1, \ldots, \beta_{\ell-1}), (r_1, \ldots, r_{\ell-1})) = (b_k - b_{\ell}) + b_{k,j} = (b_k + b_{k,j}) - b_{\ell} > 1.$$

Notably, such representations exist whenever $1 \in \{\beta_1, \ldots, \beta_{\ell-1}\}$.

On these grounds, we introduce Algorithm 7 which specifies the sufficient test applied in l.20 of Algorithm 5. The first two parameters $(\tilde{T}_1, \ldots, \tilde{T}_m)$ and $(P_1, \ldots, P_m)$ originate from Algorithm 1 while the last parameter $\ell$ originates from the calling Algorithm 5.

In l.14 of Algorithm 7 we compute $\beta_1$, ..., $\beta_{\ell-1}$ as defined in (13) and simultaneously obtain $b_1$, ..., $b_{\ell}$. In l.14 we compute the right hand sides of the conditions in (24) or (25), depending on the current index $k$. For checking those conditions in l.14 we once more employ SMT solving, this time using the adequate logic QF_LIA [2] for quantifier-free linear integer arithmetic. Since we are aiming at nonnegative integer solutions, we introduce explicit non-negativity conditions $r_1 \geq 0$, ..., $r_{\ell-1} \geq 0$. In
Algorithm 7 TestSmoothness

Input: \((T_1, \ldots, T_m), (P_1, \ldots, P_m), \ell\) as in the calling Algorithm 5
1. \((T_1, \ldots, T_m)\), a list of lists \(z_k = \delta^{b_k} f_k\);
2. \((P_1, \ldots, P_m)\), a list of lists of polynomials in \(\mathbb{Q}[x_1, \ldots, x_n][\delta]\);
3. \(\ell \in \mathbb{N}, \ell \geq 2\);

We check here a sufficient criterion for smoothness as required for \(\text{Algorithm 16}\).

Output: 'true' or 'failed' in terms of a 3-valued logic;
1: \(b_1 := 0\)
2: \(\textbf{for } k := 2 \textbf{ to } \ell \textbf{ do}\)
3: \(b_k := \text{the unique exponent of } \delta \text{ in } T_k\)
4: \(\beta_{k-1} := b_k - b_{k-1}\)
5: \(\textbf{if } \beta_{k-1} = 1 \textbf{ then}\)
6: \(\textbf{return } \text{true}\)
7: \(\textbf{end if}\)
8: \(\textbf{end for}\)
9: \(E := \varnothing\)
10: \(\textbf{for } k = 1 \textbf{ to } m \textbf{ do}\)
11: \(\textbf{for all } p \text{ in } P_k \textbf{ do}\)
12: \(E := E \cup \{ \deg_{\delta} m - b_{\text{min}(k, \ell)} | m \text{ monomial of } p \}\)
13: \(\textbf{end for}\)
14: \(\textbf{end for}\)
15: \(\textbf{for all } e \in E \textbf{ do}\)
16: \(\textbf{if not } \mathbb{Z} \models \exists r_1 \ldots \exists r_{\ell-1} (r_1 \geq 0 \land \ldots \land r_{\ell-1} \geq 0 \land (\langle \beta_1, \ldots, \beta_{\ell-1} \rangle, (r_1, \ldots, r_{\ell-1})) = e) \textbf{ then}\)
17: \(\textbf{return } \text{failed}\)
18: \(\textbf{end if}\)
19: \(\textbf{end for}\)
20: \(\textbf{return } \text{true}\)

case of unsatisfiability Algorithm 5 returns “failed” in line 17. When this happens, the calling Algorithm 5 issues a warning but continues. This protocol is owed to the fact that our procedure provides only a sufficient test, which could be supplemented with other software or human intuition. In case of satisfiability, in contrast, smoothness is guaranteed, we reach line 20 and return “true.” We remark that the computation time spent on \(E\) is negligible compared to the SMT solving later on. The construction of the entire set \(E\) beforehand avoids duplicate SMT instances.

4. Algebraic Simplification of Reduced Systems

In the output \((M_0, T_1, R_1), \ldots, (M_{\ell-1}, T_\ell, R_\ell)\) of Algorithm 5 the \(T_k\) are taken literally from the input, and the \(M_{k-1}\) and \(R_k\) are obtained via quite straightforward rewriting of the input. As a matter of fact, the computationally hard part of Algorithm 5 consists in the computation of the upper index \(\ell\). We now want to rewrite the triplets \((M_{k-1}, T_k, R_k)\) once more, aiming at less straightforward but simpler and, hopefully, more intuitive representations. The principal idea is to heuristically eliminate on the right hand side of the differential equations in \(T_k\) those variables whose derivatives have already occurred as left hand sides in one of the \(T_1, \ldots, T_{k-1}\). Of course, our simplifications will preserve all relevant properties of \((M_0, T_1, R_1), \ldots, (M_{\ell-1}, T_\ell, R_\ell)\), such as hyperbolic attractivity and sufficient differentiability. Technically, our next Algorithm 8 employs Gröbner basis techniques.

Recall that \(z_k\) are the variables occurring on the left hand sides of differential equations in \(T_k\), and \(Z_{k-1} = (z_1, \ldots, z_{k-1})\). In line 8 we construct a block term order \(\omega\) on all variables \(\{x_1, \ldots, x_n\}\) so that variables from \(Z_{k-1}\) are larger than variables from \(z_k\). This ensures that all multivariate polynomial reductions modulo \(\omega\) throughout our algorithm will eliminate variables from \(Z_{k-1}\) in favor of variables
Algorithm 8 SimplifyReducedSystems

Input: A list \((M_0, T'_1, R_1), \ldots, (M_{\ell-1}, T'_\ell, R_\ell)\), the output of Algorithm 5 with entries corresponding to \((20)\).

Output: A list \((M'_0, T'_1, R_1), \ldots, (M'_{\ell-1}, T'_\ell, R_\ell)\); \(M'_{k-1}\) describes the same manifold as \(M_{k-1}\) in a canonical form; the system \(T'_k\) is equivalent to \(T_k\) modulo \(M'_{k-1}\), its right hand sides are in a canonical normal form modulo \(M'_{k-1}\), possibly with fewer different differential variables than \(T_k\).

1: for \(k := 1\) to \(\ell\) do
2: \(z_k := \{ x \mid x' = g \in T_k \}\)
3: end for
4: \(y := \{ x \mid x' = 0 \in R_\ell \}\)
5: \(\omega := \text{a block term order with } z_1 \gg \cdots \gg z_\ell \gg y\)
6: for \(k := 1\) to \(\ell\) do
7: \(F := \{ f \mid f = 0 \in M_{k-1} \}\)
8: \(G := \text{GroebnerBasis}(\text{Radical}(F), \omega)\)
9: \(M'_{k-1} := \{ g = 0 \mid g \in G \}\)
10: \(T'_k := ()\)
11: for \(x' = g \in T_k\) do
12: \(T'_k := T'_k \circ (x' = h)\) where \(g \longrightarrow_G h\) and \(h\) is irreducible mod \(G\)
13: end for
14: end for
15: return \((M'_0, T'_1, R_1), \ldots, (M'_{\ell-1}, T'_\ell, R_\ell)\)

from \(z_k\) rather than vice versa. Prominent examples for such block orders are pure lexicographical orders, but ordering by total degree inside the \(z_1, \ldots, z_\ell\), \(y\) will heuristically give more efficient computations.

Recall that the radical ideal \(\sqrt{\langle F \rangle}\) of \(F\) is the infinite set of all polynomials with the same common complex roots as \(F\). In \(l[8]\) we compute a finite reduced Gröbner basis \(G\) modulo \(\omega\) of that radical. If radical computation is not available on the software side, then the algorithm remains correct with a Gröbner basis of the ideal \(\langle F \rangle\) instead of the radical ideal, but might miss some simplifications.

In \(l[9]\) the polynomials in \(G\) equivalently replace the left hand side polynomials of the equations in \(M_{k-1}\). In \(l[12]\) reduction modulo \(\omega\), which comes with heuristic elimination of variables, applies once more to the reduction results \(h\) obtained from right hand sides \(g\) of differential equations in \(T_k\). Since \(G\) is a Gröbner basis, the reduction in \(l[11][12]\) furthermore produces unique normal forms with the following property: if two polynomials \(g_1, g_2\) coincide on the manifold \(M_{k-1}\) defined by \(M_{k-1}\), then they reduce to the same normal form \(h\). In particular, if \(g_1\) vanishes on \(M_{k-1}\), then it reduces to 0.

We call the output of Algorithm 5 simplified reduced systems.

5. Back-Transformation of Reduced Systems

Let \(\ell \in \{2, \ldots, m\}\) and \(k \in \{1, \ldots, \ell\}\). Recall that a triplet \((M_{k-1}, T_k, R_k)\) obtained from Algorithm 5 describes a reduced system according to \((20)\). A corresponding simplified system \((M'_{k-1}, T'_k, R'_k)\) is obtained from Algorithm 8 via an equivalence transformation on the set of equations \(M_{k-1}\) and further equivalence transformations modulo \(M_{k-1}\) on the right hand sides of the differential equations in \(T_k\), while the left hand sides of those differential equations remain untouched. It is not hard to see that for both these outputs scaling can be reversed using the substitution

\[
\sigma = [x_1 \leftarrow y_1/\varepsilon^{d_1}, \ldots, x_n \leftarrow y_n/\varepsilon^{d_n}] \circ [\tau \leftarrow \varepsilon^{h_1} t] \circ [\delta \leftarrow \varepsilon^{1/q}] \circ [\varepsilon \leftarrow \varepsilon^*]
\]

obtained with Algorithm [1]. For our discussion here, we use names \(M_{k-1}, T_k, R_k\) as in the unsimplified system.

The application of \(\sigma\) to all components of \((M_{k-1}, T_k, R_k)\) yields a raw back-transformation as follows:

\[
M_{k-1}\sigma = (f_j = 0 \mid x_j \in Z_{k-1})\sigma = (f_j\sigma = 0 \mid x_j \in Z_{k-1})
\]
Moreover, the differential equations perturbation theory is typically concerned with asymptotic results, which are not helpful here.

We are now faced with a discrepancy. On the one hand, we fix \( \varepsilon = \varepsilon_{\ast} \). On the other hand, the requirement that \( \delta \) be sufficiently small in Theorem 1 entails that \( \varepsilon \) be sufficiently small. It is of crucial importance whether invariant manifolds of (3) which do exist for sufficiently small \( \varepsilon \), persist at \( \varepsilon = \varepsilon_{\ast} \). We are not aware of any algorithmic results addressing this question. In particular, singular perturbation theory is typically concerned with asymptotic results, which are not helpful here.

In case of persistence, there exist nested invariant manifolds \( \mathcal{M}_{\ell - 1} \) which are Hausdorff-close to \( \mathcal{M}_{\ell - 1}^{\ast} \) for system (1). Moreover, the differential equations \( T_{\ell}^{\ast} \) associated with \( \mathcal{M}_{\ell - 1}^{\ast} \) correspond to the \( k \)th
the concentrations of which over time we map to differential variables \( S_b \) database, a repository of mathematical models of biological processes [34]. The model specifies four in the Philippines in August 2017 [35]. That model is identified as BioModels BIOMD0000000716 in the BioModels database, a repository of mathematical models of biological processes [34]. The model specifies four species: \( S_b \) (susceptible bird), \( I_b \) (infected bird), \( S_h \) (susceptible human), and \( I_a \) (infected human), the concentrations of which over time we map to differential variables \( y_1, y_2, y_3, y_4 \), respectively. The

## Algorithm 10 TropicalMultiReduce

**Input:**
1. A list \( S = (y_1 = f_1, \ldots, y_n = f_n) \) of autonomous first-order ordinary differential equations where \( f_1, \ldots, f_n \in \mathbb{Q}[y_1, \ldots, y_n] \);
2. \( \varepsilon \in (0,1) \cap \mathbb{Q} \);
3. \( p \in \mathbb{N} \setminus \{0\} \)

**Output:** A list \( (\mathcal{M}_0, T_1^\varepsilon, R_1^\varepsilon), \ldots, (\mathcal{M}_{m-1}, T_m^\varepsilon, R_m^\varepsilon) \) of triplets where \( \ell \in \{2, \ldots, m\} \), or the empty list. For \( k \in \{1, \ldots, \ell\} \), \( M_k^\varepsilon \) is a list of real constraints defining \( \mathcal{M}_k^\varepsilon \subseteq \mathbb{R}^n \); \( T_k^\varepsilon \) is a list of differential equations; \( R_k^\varepsilon \) is a list of trivial differential equations \( \dot{y} = 0 \) for all differential variables from \( T_{k+1}^\varepsilon, \ldots, T_m^\varepsilon \).

The relevance of the output in terms of the input is discussed in Sect. 5.

1. TropicalC\(_{S,\varepsilon,\pi}\) := curry(TropicalC, \( S, \varepsilon, \pi \)) TropicalC\(_{S,\varepsilon,\pi}\) is a binary function
2. TropicalD\(_{S,\varepsilon,\pi}\) := curry(TropicalD, \( S, \varepsilon, \pi \)) TropicalD\(_{S,\varepsilon,\pi}\) is a constant function
3. \( T, P, \sigma := \text{ScaleAndTruncate}(S, \text{TropicalC}_{S,\varepsilon,\pi}, \text{TropicalD}_{S,\varepsilon,\pi}, \varepsilon) \)
4. \( \Sigma := \text{ComputeReducedSystems}(T, P) \)
5. \( \Sigma' := \text{SimplifyReducedSystems}(\Sigma) \)
6. \( \Sigma^* := \text{TransformBack}(\Sigma', \sigma) \)
7. return \( \Sigma^* \)

level in a hierarchy of time scales and approximate the flow on \( \mathcal{N}_{k-1}^\varepsilon \). We have achieved a decomposition of \( \mathcal{N}_k^\varepsilon \) into \( \ell \) systems of smaller dimension. At the very least, one obtains a well-educated guess about possible candidates for invariant manifolds and reductions. For the investigation of those candidates one may check the \( \mathcal{N}_k^\varepsilon \) for approximate invariance using, e.g., numerical methods, or by applying criteria proposed in [32].

Algorithm 10 provides a wrapper combining all our algorithms to decompose input systems like (1) into several time scales. The underlying tropicalization is not made explicit, and the result is presented on the original scale. Figure 5 explains the functional dependencies and principal data flow between our algorithms graphically.

## 6. Computational Examples

Based on our explicit algorithms in the present work, we have developed two independent software prototypes realizing all methods described here. The first one is in Python using Sympy [40] for symbolic computation, pySMT [24] as an interface to the SMT solver MathSAT5 [12], and SMTCut for the computation of tropical equilibrations [39]. The second one is a Maple package, which makes use of Maple’s built-in SMTLIB package [22] for using the SMT solver z3 [17]. For our computations here we have used our Python code. Computation results are identical with both systems, and timings are similar. We have conducted our computations on a standard desktop computer with an 3.3 GHz 6-core Intel 5820K CPU and 16 GB of main memory. Computation times listed are CPU times.

In the next subsection, we will discuss in detail the computations for one specific biological input system from the BioModels database. The subsequent subsections showcase several further such examples in a more concise style. The focus here is on biological results. For an illustration of our algorithms, we discuss in Appendix A examples where reduction stops at \( \ell < m \) for various reasons.

### 6.1. An Epidemic Model of the Bird Flu Virus H5N6

We consider a model related to the transmission dynamics of subtype H5N6 of the influenza A virus in the Philippines in August 2017 [35]. That model is identified as BioModels BIOMD0000000716 in the BioModels database, a repository of mathematical models of biological processes [34]. The model specifies four species: \( S_b \) (susceptible bird), \( I_b \) (infected bird), \( S_h \) (susceptible human), and \( I_a \) (infected human), the concentrations of which over time we map to differential variables \( y_1, y_2, y_3, y_4 \), respectively.
1. $S = (\dot{y}_1 = g_1, \ldots, \dot{y}_n = g_n)$
2. $\varepsilon^*$
3. $p$

Figure 1: Functional dependencies (thin arrows) and principal data flow (thick arrows) between our algorithms
input system is given by

\[ S = \frac{d}{dt} y_1 = -\frac{9137}{2035182} y_1 y_2 - \frac{1}{729} y_1 + \frac{412}{729}, \]
\[ \frac{d}{dt} y_2 = \frac{9137}{2035182} y_1 y_2 - \frac{4652377}{56184140} y_2, \]
\[ \frac{d}{dt} y_3 = -\frac{1}{6195375000} y_2 y_3 - \frac{1}{2025} y_1 + \frac{40758549}{2025000000}, \]
\[ \frac{d}{dt} y_4 = \frac{1}{6195375000} y_2 y_3 - \frac{1}{2841525000000} y_1. \]

We choose \( \varepsilon_* = \frac{1}{3} \), \( p = 1 \), and Algorithm 3 non-deterministically selects \( d = (1, -1, -4, -7, -3) \) from the tropical equilibration. Algorithm 1 then yields the following scaled and truncated system with three time scales:

\[ T_1 = \left[ \frac{d}{dt} x_1 = 1 \cdot (\frac{57109625}{2035182} x_1 x_2 + \frac{412}{365}) \right], \]
\[ T_2 = \left[ \frac{d}{dt} x_2 = \delta^3 \cdot (\frac{57109625}{2035182} x_1 x_2 - \frac{116109445}{192368250} x_2) \right], \]
\[ T_3 = \left[ \frac{d}{dt} x_3 = \delta^6 \cdot (\frac{15625}{25258} x_3 + \frac{40758549}{182500000}) \right], \]
\[ \frac{d}{dt} x_4 = \delta^6 \cdot (\frac{15625}{15769} x_2 x_3 - \frac{112500173}{181837680} x_4). \]

From this input, Algorithm 5 produces the following reduced systems:

\[ M_0 = [\ ] \]
\[ T_1 = \left[ \frac{d}{dt} x_1 = 1 \cdot (\frac{57109625}{2035182} x_1 x_2 + \frac{412}{365}) \right], \]
\[ R_1 = \left[ \frac{d}{dt} x_2 = 0, \frac{d}{dt} x_3 = 0, \frac{d}{dt} x_4 = 0 \right], \]
\[ M_1 = \left[ \frac{2084378125}{x_1 x_2 - 1085694984} = 0 \right], \]
\[ T_2 = \left[ \frac{d}{dt} x_2 = \delta^3 \cdot (\frac{57109625}{2035182} x_1 x_2 - \frac{116109445}{192368250} x_2) \right], \]
\[ R_2 = \left[ \frac{d}{dt} x_3 = 0, \frac{d}{dt} x_4 = 0 \right], \]
\[ M_2 = \left[ \frac{2084378125}{x_1 x_2 - 1085694984} = 0 \right], \]
\[ 16675025 x_1 x_2 - 4652377 x_2 = 0 \], \]
\[ T_3 = \left[ \frac{d}{dt} x_3 = \delta^6 \cdot (\frac{15625}{25258} x_3 + \frac{40758549}{182500000}) \right], \]
\[ \frac{d}{dt} x_4 = \delta^6 \cdot (\frac{15625}{15769} x_2 x_3 - \frac{112500173}{181837680} x_4 \right], \]
\[ R_3 = [\ ] \]

In that course, Algorithm 6 successfully tests all three scaled systems for hyperbolic attractivity. Furthermore, Algorithm 7 applies the sufficient smoothness test from Sect. 3.3 with

\[ \ell = 3, \quad b_1 = 3, \quad b_2 = 3, \quad P_1 = 1 \cdot (\delta^4 \cdot \frac{125}{18} x_1), \quad P_2 = \delta^6 \cdot (\delta^4 \cdot \frac{15625}{36} x_2 x_3). \]

This yields \( E = \{4\} \), where 4 cannot be expressed as an integer multiple of 3. Thus the test fails, which causes a warning in Algorithm 5. Notice that in \( R_1, \ldots, R_\ell \) the differential variables are ordered in the same way as in the scaled and truncated system \( T_1, \ldots, T_\ell \). Incidentally, this coincides with the lexicographic order in this example.

Algebraic simplification through Algorithm 8 yields the simplified reduced systems

\[ M'_0 = [\ ] \]
\[ T'_1 = \left[ \frac{d}{dt} x_1 = 1 \cdot (\frac{57109625}{2035182} x_1 x_2 + \frac{412}{365}) \right], \]
\[ R'_1 = \left[ \frac{d}{dt} x_2 = 0, \frac{d}{dt} x_3 = 0, \frac{d}{dt} x_4 = 0 \right], \]
\[ M'_1 = \left[ x_1 x_2 = \frac{1085694984}{2084378125} \right], \]
\[ T'_2 = \left[ \frac{d}{dt} x_2 = \delta^3 \cdot (\frac{116109445}{192368250} x_2 + \frac{412}{365}) \right], \]
\[ R'_2 = \left[ \frac{d}{dt} x_3 = 0 \right], \]
\[ M_2' = \begin{bmatrix} x_1 = \frac{4652377}{20940925}, \\ x_2 = \frac{1085694984}{681541125} \end{bmatrix}, \quad \frac{d}{dt} x_4 = 0, \]

\[ T_2' = \begin{bmatrix} \frac{d}{dt} x_3 = 6^6 \cdot \left( -\frac{15625}{20940925} x_3 + \frac{4078549}{12008000} \right), \\ \frac{d}{dt} x_4 = 6^6 \cdot \left( \frac{1884887125}{101870566 x_3 - \frac{112500173}{181857600} x_4} \right), \\ R_2' = [\cdot] \]

Notice that our implementations conveniently rewrite equalional constraints as monomial equations with numerical right hand sides when possible. This supports readability but is not essential for the simplifications applied here, which are based on Gröbner basis theory. Comparing \( T_2' \) with \( T_2 \), we see that the equation for \( x_1 x_2 \) in \( M_1' \) is plugged in. Similarly, \( M_2 \) is simplified to \( M_2' \), which is in turn used to reduce \( T_3 \) to \( T_3' \).

The back-transformed reduced systems as computed by Algorithm \( 9 \) read as follows:

\[ M_0' = [\cdot], \quad T_1' = \begin{bmatrix} \frac{d}{dt} y_1 = 1 \cdot \left( -\frac{9137}{2630157} y_1 y_2 + \frac{412}{74} \right), \\ \frac{d}{dt} y_3 = 0, \\ \frac{d}{dt} y_4 = 0, \\ R_1' = [\cdot] \]

\[ M_1' = \begin{bmatrix} y_1 y_2 = \frac{1085694984}{681541125} \end{bmatrix}, \quad T_2' = \begin{bmatrix} \frac{d}{dt} y_3 = \frac{1}{125} \cdot \left( -\frac{116309425}{192250829} y_2 + \frac{5100}{74} \right), \\ \frac{d}{dt} y_3 = 0, \\ \frac{d}{dt} y_4 = 0, \\ R_2' = [\cdot] \]

\[ M_2' = \begin{bmatrix} y_1 = \frac{4652377}{3335005}, \\ y_2 = \frac{5428474920}{46923177} \end{bmatrix}, \quad T_3' = \begin{bmatrix} \frac{d}{dt} y_3 = \frac{1}{15625} \cdot \left( -\frac{15625}{225585} y_3 + \frac{203792745}{1108} \right), \\ \frac{d}{dt} y_4 = \frac{1}{15625} \cdot \left( \frac{50943312817}{181857600} y_4 - \frac{112500173}{181857600} y_4 \right), \\ R_3' = [\cdot] \]

We compare \( T_1', \ldots, T_3' \) to the input system \( S \): In the equation for \( y_1 \), the monomial in \( y_1 \) is identified as a higher order term with respect to \( \delta \) and discarded by Algorithm \( 1 \). In the equation for \( y_2 \), the monomial in \( y_1 y_2 \) has been Gröbner-reduced to a constant modulo the defining equation in \( M_1'. \) Similarly, the equation for \( y_3 \) loses its monomial in \( y_2 y_3 \) by truncation of higher order terms, and in the equation for \( y_4 \), the monomial in \( y_2 y_3 \) is Gröbner-reduced to a monomial in \( y_3 \).

Notice the explicit constant factors on the right hand sides of the differential equations in \( T_1', \ldots, T_3' \). They originate from factors \( \delta^{9y} \) in the respective scaled systems \( T_1, \ldots, T_3 \), corresponding to \( 8 \). They are left explicit to make the time scale of the differential equations apparent. We see that the system \( T_2' \circ R_2 \) is 125 times slower than \( T_1 \circ R_1 \), and \( T_3' \circ R_3 \) is another 125 times slower.

Figure \( 3 \) visualizes the direction fields of \( T_2' \circ R_2, \ldots, T_3' \circ R_3 \) on their respective manifolds \( M_0', \ldots, M_2' \) along with their respective critical manifolds \( M_1', \ldots, M_3' \), where \( M_0' \) can be derived from \( M_2' \) by additionally equating the vector field of \( T_3' \circ R_3 \) to zero:

\[ M_0' = \begin{bmatrix} y_1 = \frac{4652377}{3335005}, \\ y_2 = \frac{5428474920}{46923177}, \\ y_3 = \frac{7051228977}{290600}, \\ y_4 = \frac{441466240042010928888}{327212076085063125} \end{bmatrix} \]

This list \( M_0' \) does not explicitly occur in the output. However, its preimage \( M_3 \) is constructed in Algorithm \( 8 \) and justifies the presence of \( (M_2, T_3, R_3) \) in the output there. The total computation time was 0.906 s.

This multiple time scale reduction of the bird flu model emphasizes a cascade of successive relaxations of different model variables. First, the population of susceptible birds relaxes. As explained in the introduction, by relaxation we mean that these variables reach quasi-steady state values. This relaxation is illustrated in Fig. \( 2(b) \). Then, the population of infected birds relaxes as shown in Fig. \( 2(c) \). Finally, the populations of susceptible and infected humans relax to a stable steady state as shown in Fig. \( 2(d) \), following a reduced dynamics described by \( T_3' \).
Figure 2: Critical manifolds and direction fields of our reductions of BioModel 716. (a) The surface is the critical manifold $\mathcal{M}_1^* \subseteq \mathcal{M}_0^* = \mathcal{U}$ projected from $\mathbb{R}^4$ into real $(y_1, y_2, y_3)$-space. The line located at $(y_1, y_2) \approx (1.4, 1166.8)$ is the critical submanifold $\mathcal{M}_2^* \subseteq \mathcal{M}_1^*$. The dot located at $(y_1, y_2, y_3) \approx (1.4, 1166.8, 282049.2)$ is the critical submanifold $\mathcal{M}_3^* \subseteq \mathcal{M}_2^*$. Both $\mathcal{M}_1^*$ and $\mathcal{M}_2^*$ extend to $\pm\infty$ in both $y_3$ and $y_4$ direction, and $\mathcal{M}_3^*$ is located near $(1.4, 1166.8, 282049.2, 1349.6)$. (b) The direction field of $T^*_1 \circ R^*_1$ on $\mathcal{M}_0^* = \mathcal{U}$ projected from $\mathbb{R}^4$ into real $(y_1, y_2)$-space. The curve is the critical submanifold $\mathcal{M}_1^* \subseteq \mathcal{M}_0^*$. (c) The direction field of $T^*_2 \circ R^*_2$ on $\mathcal{M}_1^*$ projected from $\mathbb{R}^4$ into real $(y_3, y_2)$-space. The line is the critical submanifold $\mathcal{M}_2^* \subseteq \mathcal{M}_1^*$. The system here is slower than the one in (b) by a factor of 125. (d) The direction field of $T^*_3 \circ R^*_3$ on $\mathcal{M}_2^*$ projected from $\mathbb{R}^4$ into real $(y_3, y_4)$-space. The dot is the critical submanifold $\mathcal{M}_3^* \subseteq \mathcal{M}_2^*$. The system here is slower than the one in (c) by another factor of 125.
6.2. Caspase Activation Pathway

BIOMDO000000102 is a quantitative kinetic model that examines the intrinsic pathway of caspase activation that is essential for apoptosis induction by various stimuli including cytotoxic stress [36]. Species concentrations over time are mapped as follows:

| Species variable | Differential variable | Species |
|------------------|-----------------------|---------|
| A                | $y_1$                 | APAF-1  |
| C9               | $y_2$                 | Caspase 9 |
| C9X              | $y_3$                 | Caspase 9-XIAP complex |
| X                | $y_4$                 | XIAP    |
| AC9X             | $y_5$                 | APAF-1-Caspase 9-XIAP complex |
| AC9              | $y_6$                 | APAF-1-Caspase 9 complex |
| C3               | $y_7$                 | Caspase 3 |
| C3_star          | $y_8$                 | Caspase 3 cleaved |
| C3_starX         | $y_9$                 | Caspase 3 cleaved-XIAP complex |
| C9_starX         | $y_{10}$              | Caspase 9 cleaved-XIAP complex |
| C9_star          | $y_{11}$              | Caspase 9 cleaved |
| AC9_star         | $y_{12}$              | APAF-1-Caspase 9 cleaved complex |
| AC9_starX        | $y_{13}$              | APAF-1-Caspase 9 cleaved-XIAP complex |

The input system is given by

$$
S = \left[ \begin{array}{c}
\frac{d}{dt} y_1 = -\frac{1}{9000} y_1 y_2 - \frac{1}{9000} y_1 y_3 - \frac{1}{9000} y_1 y_10 - \frac{1}{9000} y_1 y_11 - \frac{1}{1000} y_1 + \frac{1}{10} y_5 + \frac{1}{10} y_6 + \frac{1}{10} y_{12} \\
\frac{d}{dt} y_2 = -\frac{1}{9000} y_1 y_2 - \frac{1}{10000} y_2 y_4 - \frac{1}{10000} y_2 y_8 - \frac{1}{10000} y_2 + \frac{1}{10} y_3 + \frac{1}{10} y_6 + \frac{1}{10} y_9 \\
\frac{d}{dt} y_3 = -\frac{1}{9000} y_1 y_3 + \frac{1}{10000} y_2 y_4 - \frac{1}{10000} y_3 + \frac{1}{10} y_5, \\
\frac{d}{dt} y_4 = -\frac{1}{10000} y_2 y_4 + \frac{1}{10000} y_3 - \frac{1}{10000} y_4 y_8 - \frac{3}{10000} y_4 y_8 - \frac{1}{10000} y_4 y_11 - \frac{1}{10000} y_4 y_12 + \frac{1}{10000} y_4 \\
\frac{d}{dt} y_5 = \frac{1}{10000} y_1 y_3 + \frac{1}{10000} y_4 y_8 - \frac{51}{5000} y_5, \\
\frac{d}{dt} y_6 = \frac{1}{10000} y_1 y_2 - \frac{1}{10000} y_4 y_8 + \frac{1}{10000} y_5 - \frac{1}{10000} y_6 y_8 - \frac{101}{10000} y_6, \\
\frac{d}{dt} y_7 = -\frac{1}{20000} y_2 y_7 - \frac{7}{20000} y_3 y_7 - \frac{7}{20000} y_7 y_11 - \frac{7}{20000} y_7 y_12 - \frac{1}{10000} y_7 + \frac{1}{5}, \\
\frac{d}{dt} y_8 = \frac{1}{20000} y_2 y_7 - \frac{3}{10000} y_4 y_8 + \frac{7}{20000} y_6 y_8 + \frac{1}{20000} y_7 y_11 + \frac{7}{20000} y_7 y_12 - \frac{1}{10000} y_8 + \frac{1}{10000} y_9, \\
\frac{d}{dt} y_9 = \frac{3}{10000} y_1 y_8 - \frac{1}{10000} y_9, \\
\frac{d}{dt} y_{10} = -\frac{1}{50000} y_1 y_{10} + \frac{1}{10000} y_4 y_{11} + \frac{1}{10000} y_{10} + \frac{1}{10} y_{13}, \\
\frac{d}{dt} y_{11} = -\frac{1}{50000} y_1 y_{11} + \frac{1}{10000} y_2 y_{28} - \frac{1}{10000} y_4 y_{11} + \frac{1}{10000} y_{10} - \frac{1}{10000} y_{11} + \frac{1}{10} y_{12}, \\
\frac{d}{dt} y_{12} = \frac{1}{50000} y_1 y_{11} - \frac{1}{10000} y_4 y_{12} + \frac{1}{10000} y_6 y_{8} - \frac{101}{10000} y_{12} + \frac{1}{10000} y_{13}, \\
\frac{d}{dt} y_{13} = \frac{1}{10000} y_1 y_{10} + \frac{1}{10000} y_4 y_{12} - \frac{51}{10000} y_{13}. \\
\end{array} \right]
$$

We choose $\varepsilon_* = \frac{1}{2}$, $p = 1$ and select $d = (-4, 2, 3, 5, 4, -6, -8, -4, -2, -2, 0, 0)$ from the tropical equilibration. Our back-transformed reduced systems read as follows:

$$
M^*_0 = [ ], \\
T^*_1 = \left[ \begin{array}{c}
\frac{d}{dt} y_4 = 1 \cdot \left( -\frac{3}{10000} y_4 y_8 + \frac{1}{10} \right) \\
R^*_1 [rac{d}{dt} y_5 = 0, \frac{d}{dt} y_6 = 0, \frac{d}{dt} y_{12} = 0, \frac{d}{dt} y_{13} = 0, \\
\frac{d}{dt} y_2 = 0, \frac{d}{dt} y_3 = 0, \frac{d}{dt} y_{10} = 0, \frac{d}{dt} y_{11} = 0, \\
\frac{d}{dt} y_1 = 0, \frac{d}{dt} y_7 = 0, \frac{d}{dt} y_9 = 0, \frac{d}{dt} y_8 = 0].
\end{array} \right], \\
M^*_1 = [ y_4 y_8 = \frac{40}{4} ], \\
T^*_2 = \left[ \frac{d}{dt} y_5 = \frac{1}{2} \cdot \left( \frac{2}{10000} y_1 y_3 - \frac{102}{10000} y_6 \right) \right].
$$
The total computation time was 0.906 s.

RII_endo (endosome), and RII has a change of

6.3. TGF-β Pathway

BIOMD0000000101, is a simple representation of the TGF-β signaling pathway that plays a central role in tissue homeostasis and morphogenesis, as well as in numerous diseases such as fibrosis and cancer [40]. Concentrations over time of species RI (receptor 1), RII (receptor 2), 1RII (ligand receptor complex-plasma membrane), 1RII_endo (ligand receptor complex-endosome), RI_endo (receptor 1 endosome), and RII_endo (receptor 2 endosome), are mapped to differential variables $y_1$, $y_2$, $y_3$, $y_4$, $y_5$, and $y_6$, respectively. The original BIOMD0000000101 has a change of 1ligand concentration at time $t = 2500$. For our computation here, we ignore this discrete event. The input system is given by

$$S = \left[ \begin{array}{c}
\frac{d}{dt} y_1 = - \frac{1}{100} y_1 y_2 - \frac{9277}{250000} y_1 + \frac{33333}{10000000} y_4 + \frac{33333}{10000000} y_5 + 8,
\frac{d}{dt} y_2 = - \frac{1}{100} y_1 y_2 - \frac{9277}{250000} y_2 + \frac{33333}{10000000} y_4 + \frac{33333}{10000000} y_6 + 4,
\frac{d}{dt} y_3 = \frac{1}{100} y_1 y_2 - \frac{152777}{250000} y_3,
\frac{d}{dt} y_4 = \frac{33333}{10000000} y_3 - \frac{33333}{10000000} y_4,
\frac{d}{dt} y_5 = \frac{33333}{10000000} y_4 - \frac{33333}{10000000} y_5,
\frac{d}{dt} y_6 = \frac{33333}{10000000} y_5 - \frac{33333}{10000000} y_6
\end{array} \right].$$

We choose $\varepsilon_\star = \frac{1}{5}$, $p = 1$, and select $d = (0, -4, -1, -2, -1, -5)$ from the tropical equilibrium. Our back-transformed reduced systems read as follows:

$$M_0^* = [ ],$$

$$M_1^* = [ y_1 y_2 = 800 ],$$

$$M_2^* = [ y_1 y_2 = 800, y_3 = \frac{20000000}{152777} ],$$

$$R_1^* = \left[ \begin{array}{c}
\frac{d}{dt} y_2 = 0, \quad \frac{d}{dt} y_3 = 0, \quad \frac{d}{dt} y_4 = 0, \quad \frac{d}{dt} y_5 = 0,
\frac{d}{dt} y_6 = 0
\end{array} \right],$$

$$R_2^* = \left[ \begin{array}{c}
\frac{d}{dt} y_2 = 0, \quad \frac{d}{dt} y_3 = 0, \quad \frac{d}{dt} y_4 = 0, \quad \frac{d}{dt} y_5 = 0,
\frac{d}{dt} y_6 = 0
\end{array} \right],$$

$$R_3^* = \left[ \begin{array}{c}
\frac{d}{dt} y_2 = 0, \quad \frac{d}{dt} y_3 = 0, \quad \frac{d}{dt} y_4 = 0, \quad \frac{d}{dt} y_5 = 0
\end{array} \right].$$

The total computation time was 0.906 s.
The multiple time scale reduction of the TGF-β model emphasizes a cascade of successive relaxations of concentrations of different species. First, the concentration of receptor 1 relaxes rapidly. Then follows the membrane complex, and, even slower, the relaxation of receptor 2.

### 6.4. Avian Influenza Bird-to-Human Transmission

Biomodels examines bird-to-human transmission of different strains of avian influenza A viruses, such as H5N1 and H7N9. Species concentrations over time of $S_a$ (susceptible avian), $I_a$ (infected avian), $S_h$ (susceptible human), $I_h$ (infected human), and $R_h$ (recovered human) are mapped to differential variables $y_1$, $y_2$, $y_3$, $y_4$, and $y_5$, respectively. The input system is given by

$$S = \begin{bmatrix}
\frac{d}{dt} y_1 = -\frac{1}{8000000000000000} y_1^3 + \frac{127}{2000000000000000} y_1^2 - \frac{9}{5000000000000000} y_1 y_2 - \frac{1}{200} y_1, \\
\frac{d}{dt} y_2 = -\frac{9}{2000000000000000} y_1 y_2 - \frac{37123}{5000000000000000} y_2, \\
\frac{d}{dt} y_3 = -\frac{3}{2000000000000000} y_2 y_3 - \frac{391}{10000000000000000} y_3 + 30, \\
\frac{d}{dt} y_4 = \frac{3}{20000000000000000} y_2 y_3 - \frac{445391}{10000000000000000} y_4, \\
\frac{d}{dt} y_5 = \frac{1}{200} y_4 - \frac{391}{10000000000000000} y_5.
\end{bmatrix}$$

We choose $\epsilon_*$ = $\frac{1}{2}$, $p = 1$, and select $d = (-7,0,-8,3,-2)$ from the tropical equilibration. Our back-transformed reduced systems read as follows:

$$M_0^* = [\ ]$$

$$T_1^* = \begin{bmatrix}
\frac{d}{dt} y_1 = 1 \cdot \left( -\frac{1}{8000000000000000} y_1^3 + \frac{127}{2000000000000000} y_1^2 \right), \\
\frac{d}{dt} y_2 = 0, \\
\frac{d}{dt} y_3 = 0, \\
\frac{d}{dt} y_4 = 0, \\
\frac{d}{dt} y_5 = 0
\end{bmatrix}$$

$$M_1^* = [y_1^3 - 50800y_1^2 = 0]$$

$$T_2^* = \begin{bmatrix}
\frac{d}{dt} y_1 = 0, \\
\frac{d}{dt} y_2 = \frac{1}{2} \cdot \left( \frac{3}{20000000000000000} y_2 y_3 - \frac{445391}{10000000000000000} y_4 \right), \\
\frac{d}{dt} y_3 = 0, \\
\frac{d}{dt} y_4 = 0, \\
\frac{d}{dt} y_5 = 0
\end{bmatrix}$$

The total computation time was 0.578 s.

The multiple time scale reduction of this avian influenza model emphasizes a cascade of successive relaxations of different model variables. First, the susceptible bird population relaxes rapidly. The reduced equation $T_1$ and manifold $M_1$ suggest that the bird population dynamics is of the Allee type and evolves toward the stable extinct state. It follows the relaxation of infected human population that also evolves toward the extinct state, the end of the epidemics.

### 7. Concluding Remarks

We provided a symbolic method for automatic model reduction of biological networks described by ordinary differential equations with multiple time scales. This method is applicable to systems with two time scales or more, superseding traditional slow-fast reduction methods that can cope with only two time scales. We also proposed, for the first time, the automatic verification of the hyperbolicity conditions required for the validity of the reduction. Our theoretical framework is accompanied by rigorous algorithms and prototypical implementations, which we successfully applied to real-world problems from the BioModels database.

We would like to list some open points and possible extensions of our research here. Our reduction algorithm is based on a fixed scaling, leading to a fixed ordering of the time scales of different variables. In our reduction scheme, different variables relax hierarchically, firstly the fastest ones, then the second fastest, and lastly the slowest ones, which justifies our geometric picture of nested invariant manifolds. However, there are situations, e.g. in models of relaxation oscillations, when the ordering of time scales changes with time: variables that were fast can become slow at a later time, and vice versa. In order to cope with such situations, one would like to use different scalings for different time segments. One attempt to implement such a procedure has been provided in [54].

Although our proposed method identifies the full hierarchy of time scales, the subsequent reduction may stop early in this hierarchy when hyperbolic attractivity is not satisfied at some stage.
possible reason is the presence of conservation laws, also known as first integrals, at the given reduction stage. Such conservation laws necessarily force an eigenvalue zero for the Jacobian. A theorem by Schneider and Wilhelm [52] can be employed to reduce such a setting to the hyperbolically attractive case. As for the behavior of first integrals when proceeding to the reduced system, see the discussion of the non-standard case in [33] for two time scales; an extension to multiple time scales should be straightforward. Work in progress is concerned with the introduction of novel slow variables, one for every independent conservation law of the fast subsystem, applying this to networks with multiple time scales, and approximate linear and polynomial conservation laws.

More generally, it is of interest to consider cases when hyperbolic attractivity fails but hyperbolicity still holds: In such cases, Cardin and Teixeira show there still exist invariant manifolds [10]. Testing for hyperbolicity is more involved than testing for hyperbolic attractivity, but in theory it is well understood, and there exists an algorithmic approach due to Routh [23]. In the case of hyperbolicity, but not attractivity, the ensuing global dynamics may be quite interesting; for instance slow-fast cycles may appear.

Concerning differentiability requirements, we checked for smoothness of the full system in Sect. 3.3. However, Fenichel’s results, and in principle also those by Cardin and Teixeira, require only sufficient finite differentiability. Therefore, given a differential equation system and a scaling, invariant manifolds and corresponding reduced systems exist for \( C^p \) functions with fixed \( p < \infty \). Going through the details will involve intricate analysis that is left to future work.

In the introduction we sketched a Michaelis–Menten system abstracting from the known numerical values for the reaction rate constants \( k_1, k_{-1}, k_2 \). It would indeed be interesting to work on such parametric data. In the presence of parameters, one would consider effective quantifier elimination over real closed fields [14] [63] [31] [55] as a generalization of SMT solving. Robust implementations are freely available [8] [15] and well supported. They have been successfully applied to problems in chemical reaction network theory during the past decade [56] [62] [7] [19]. Such a generalization is not quite straightforward. With the tropical scaling in Sect. 2.2, Algorithm 2 would introduce logarithms of polynomials in the parametric coefficients, which is not compatible with the logical framework used here. Similar tropicalization methods, which are unfortunately not compatible with our abstract view on scaling in Sect. 2.1, require only logarithms of individual parametric coefficients [51]. Such a more special form would allow the use of abstraction in the logic engine.

From a point of view of user-oriented software, it would be most desirable to develop automatic strategies for determining good default values for \( \varepsilon_* \) and for choices of \( d \) from the tropical equilibration in Algorithm 3.

A. Illustration of Some Border Cases With Our Algorithms

A.1. Failure of Tropicalization With an Unbalanced Monomial

BIOMD0000000609 describes the metabolism and the related hepatotoxicity of acetaminophen, a pain killer [48]. The species concentrations over time of Sulphate__PAPS, GSH, NAPQI, Paracetamol_APAP, and Protein_adducts are mapped to differential variables \( y_1, y_2, y_3, y_4, \) and \( y_5 \), respectively. The input system is given by

\[
S = \begin{bmatrix}
\frac{d}{dt} y_1 &=& -2260000000000000000y_1y_4 - 2y_1 + 5320000000000000000, \\
\frac{d}{dt} y_2 &=& -1600000000000000000y_2y_3 - 2y_2 + 6872000000000000000, \\
\frac{d}{dt} y_3 &=& -1600000000000000000y_2y_3 - 2206320000000000000, \\
\frac{d}{dt} y_4 &=& -2260000000000000000y_1y_4 + 6320000000000000000, \\
\frac{d}{dt} y_5 &=& 110y_3.
\end{bmatrix}
\]

Since there is only one monomial on the right hand side of the equation for \( y_5 \), equilibration is impossible. This causes Algorithm 4 to return in line 23 a disjunctive normal form equivalent to "false", which describes the empty set. Hence Algorithm 3 returns \( \bot \), and Algorithm 1 returns the empty list. The total computation time was 0.006 s.

A.2. Failure of Hyperbolic Attractivity due to an Empty Manifold in the First Orthant

BIOMD0000000726 examines the transmission dynamics of rabies between dogs and humans [49]. The mapping of the model variables over time and our differential variables is as follows:

| Species | Differential variable | Description         |
|---------|----------------------|---------------------|
| S_d     | y_1                  | susceptible dogs    |
| E_d     | y_2                  | exposed dogs        |
| I_d     | y_3                  | infectious dogs     |
| R_d     | y_4                  | recovered dogs      |
| S_h     | y_5                  | susceptible humans  |
| E_h     | y_6                  | exposed humans      |
| I_h     | y_7                  | infectious humans   |
| R_h     | y_8                  | recovered humans    |

The input system is given by

\[
S = \begin{bmatrix}
\frac{d}{dt} y_1 &=& -\frac{79}{500000000}y_1y_3 - \frac{17}{100}y_1 + \frac{18}{5}y_2 + y_4 + 3000000, \\
\frac{d}{dt} y_2 &=& \frac{79}{500000000}y_1y_3 + 61\frac{17}{100}y_2, \\
\frac{d}{dt} y_3 &=& \frac{12}{5}y_2 - 27\frac{7}{5}y_3.
\end{bmatrix}
\]
\[
\begin{align*}
\frac{d}{dt} y_4 &= \frac{9}{100}y_1 + \frac{\sqrt{5}}{20}y_2 - \frac{27}{25}y_4, \\
\frac{d}{dt} y_5 &= -\frac{3}{1000000000000}y_3 y_5 - \frac{3}{1000}y_5 + \frac{18}{5}y_6 + y_8 + 15400000, \\
\frac{d}{dt} y_6 &= \frac{229}{1000000000000}y_3 y_5 - \frac{6543}{1000}y_6, \\
\frac{d}{dt} y_7 &= \frac{12}{5}y_6 - \frac{1343}{1000}y_7, \\
\frac{d}{dt} y_8 &= \frac{27}{50}y_6 - \frac{1009}{1000}y_8.
\end{align*}
\]

We choose parameters \(\varepsilon_* = \frac{1}{2}, p = 1\), and \(d = (−10, −10, −11, −9, −14, −7, −8, −7)\). The condition in \(11\) of Algorithm 6 does not hold for

\[
M = [−9875x_1 x_3 + 4608x_2 = 0, \quad 49375x_1 x_3 − 39488x_2 = 0, \quad 17890625x_3 x_5 − 13400064x_6 = 0],
\]

i.e., the corresponding manifold \(M_1\) is empty. Consequently, Algorithms 5, 8, and 9 return empty lists. The total computation time was 0.921 s.

### A.3. Failure of Hyperbolic Attractivity in the First Step

BIO MD 00000000156 examines the dynamics of a negative feedback loop between the tumor suppressor protein p53 and the oncogene protein Mdm2 in human cells [25]. The species concentrations over time for \(x\) (p53), \(y\) (Mdm2), and \(y_0\) (precursor Mdm2) are mapped to differential variables \(y_1\), \(y_2\), and \(y_3\), respectively. The input system is given by

\[
S = \begin{bmatrix}
\frac{d}{dt} y_1 = -\frac{17}{10} y_1 y_2 + 2 y_1, \\
\frac{d}{dt} y_2 = -\frac{9}{10} y_2 + \frac{11}{10} y_3, \\
\frac{d}{dt} y_3 = \frac{3}{2} y_1 - \frac{11}{10} y_3
\end{bmatrix}.
\]

We choose parameters \(\varepsilon_* = \frac{1}{2}, p = 1\), and point \(d = (2, 1, 1)\). Algorithm 5 returns an empty list, since the test for hyperbolic attractivity fails in Algorithm 6, l.20, even though the manifold \(M_1\), defined by \(M_1 = [−\frac{17}{10} x_1 x_3 + x_3 = 0]\), is not empty in the first orthant, as has been ensured in \(11\). Obviously, the simplified and back-translated systems are empty lists as well. The total computation time was 0.453 s.

### A.4. Failure in SMT Solving for a Reduced System With Fractional Exponents

BIO MD 00000000663 illustrates how CD4 T-cells can influence the spread of the HIV infection [64]. Species concentrations over time for \(x\) (\(\text{v}_\text{free}_\text{virus}\)), \(y\) (\(\text{v}_\text{Tcell}_\text{infected}\)), and \(y_0\) (\(\text{v}_\text{Tcell}_\text{uninfected}\)) are mapped to variables \(y_1\), \(y_2\), and \(y_3\), respectively. The input system is given by

\[
S = \begin{bmatrix}
\frac{d}{dt} y_1 = -\frac{17}{10} y_1 y_2 - \frac{1}{10} y_1 y_3 - \frac{1}{10} y_1, \\
\frac{d}{dt} y_2 = -\frac{1}{10} y_2 y_3 + \frac{1}{5} y_1 y_3 - \frac{1}{10} y_2^2 y_3 + y_2 y_3 - \frac{1}{5} y_2, \\
\frac{d}{dt} y_3 = y_2 - \frac{7}{5} y_1
\end{bmatrix}.
\]

We choose \(\varepsilon_* = \frac{1}{2}, p = 5\), and \(d = (1, 4, 3)\). The choice of \(p = 5\) causes fractional exponents in the scaled and truncated system, viz.

\[
T_2 = \begin{bmatrix}
\frac{d}{dt} x_2 = \delta^7 \cdot (\frac{4}{5} \sqrt[3]{x_1} x_3 - \frac{4}{5} \sqrt[3]{x_2})
\end{bmatrix}, \quad T_3 = \begin{bmatrix}
\frac{d}{dt} x_1 = \delta^{12} \cdot (\frac{4}{5} \sqrt[3]{x_1} x_3 - \frac{4}{5} \sqrt[3]{x_1})
\end{bmatrix}.
\]

However, the relevant SMT logics QA_LRA and QA NRA do not accept fractional exponents. Recall from Sect. 3.2 that in such cases, we catch the corresponding error from the SMT solver, convert to floats, and restart.

We then get into the special case that \(\ell = 1\) in l.16 of Algorithm 5, i.e., there are less than two reduced systems, and return the empty list. Consequently, the list of simplified reduced systems and the corresponding list of back-transformed systems are empty as well. Notice that this special case is not caused by the fractional exponents discussed above. The total computation time was 0.390 s.
