Second-Order Coding Rates for Entanglement-Assisted Communication

Nilanjana Datta∗ Marco Tomamichel† Mark M. Wilde‡
May 9, 2014

Abstract

The entanglement-assisted capacity of a quantum channel is known to provide the formal quantum generalization of Shannon’s classical channel capacity theorem, in the sense that it admits a single-letter characterization in terms of the quantum mutual information and does not increase in the presence of a noiseless quantum feedback channel from receiver to sender. In this work, we investigate the second-order asymptotics of the entanglement-assisted communication task. That is, we consider how quickly the rates of entanglement-assisted codes converge to the entanglement-assisted capacity of a channel as a function of the number of channel uses and the error tolerance. We define a quantum generalization of the mutual information variance of a channel in the entanglement-assisted setting. For covariant channels, we show that this quantity is equal to the channel dispersion, and characterizes the convergence towards the entanglement-assisted capacity when the number of channel uses increases. More generally, we prove that the Gaussian approximation of the second-order coding rate is achievable for all quantum channels.

1 Introduction

Entanglement is a valuable resource in information-processing tasks in the quantum setting. Hence, understanding how entanglement can be exploited to enhance the performance of tasks in communication and computation is an issue of central importance in quantum information science.

The task on which we focus here is the transmission of classical information through a memoryless quantum channel. If the sender and receiver initially share entangled states which they may use in their communication protocol, then the information transmission is said to be entanglement-assisted. The entanglement-assisted classical capacity $C_{ea}(N)$ of a quantum channel $N$ is defined to be the maximum rate at which a sender and receiver can communicate classical information with vanishing error probability by using the channel $N$ as many times as they wish and by using an arbitrary amount of shared entanglement of an arbitrary form. For a noiseless quantum channel, the entanglement-assisted classical capacity is twice as large as its unassisted one, an enhancement realized by the super-dense coding protocol [BW92].

Similarly, for a noisy quantum channel, the presence of entanglement as an auxiliary resource can also lead to an enhancement of its classical capacity \[\text{BSST99}\] \[\text{BSST02}\]. Somewhat surprisingly, entanglement assistance is advantageous even for some entanglement-breaking channels \[\text{HSR03}\], such as depolarizing channels with sufficiently high error probability. Bennett, Shor, Smolin and Thapliyal \[\text{BSST02}\] proved that the entanglement-assisted classical capacity \(C_{\text{ea}}(N)\) of a quantum channel \(N\) is given by a remarkably simple, single-letter formula in terms of the quantum mutual information (defined in the following section). This is in contrast to the unassisted classical capacity of a quantum channel \[\text{Hol02b}\] \[\text{SW97}\], for which the best known general expression involves a regularization of the Holevo formula over infinitely many instances of the channel \[\text{Has09}\]. The regularization renders the explicit evaluation of the capacity for a general quantum channel intractable.

The formula for the entanglement-assisted capacity is formally analogous to Shannon’s well-known formula \[\text{Sha48}\] for the capacity of a discrete memoryless classical channel, which is given in terms of the mutual information between the channel’s input and output. The entanglement-assisted capacity does not increase under the presence of a noiseless quantum feedback channel from receiver to sender \[\text{Bow04}\], much like the capacity of a classical channel does not increase in the presence of a noiseless classical feedback link \[\text{Sha56}\].

The formula for \(C_{\text{ea}}(N)\) derived in \[\text{BSST99}\], however, is only relevant if the channel is available for as many uses as the sender and receiver wish, with there being no correlations in the noise acting on its successive inputs.\(^1\) To see this, let us consider the practical scenario in which a memoryless channel is used a finite number \(n\) times, and let \(N^n \equiv N \otimes_n\). Let \(\log M^*_\text{ea}(N^n, \varepsilon)\) denote the maximum number of bits of information that can be transmitted through \(n\) uses of the channel via an entanglement-assisted communication protocol, such that the average probability of failure is no larger than \(\varepsilon \in (0, 1)\). Then \[\text{BSST99}\] and the strong converse \[\text{BDH}^+14\] \[\text{BCR11}\] imply that

\[
\lim_{n \to \infty} \frac{1}{n} \log M^*_\text{ea}(N^n, \varepsilon) = C_{\text{ea}}(N). \tag{1.1}
\]

We are interested in investigating the behavior of \(M^*_\text{ea}(N^n, \varepsilon)\) for large but finite \(n\) as a function of \(\varepsilon\). In this paper, we derive a lower bound on \(\log M^*_\text{ea}(N^n, \varepsilon)\), for any fixed value of \(\varepsilon \in (0, 1)\) and \(n\) large enough, of the following form:

\[
\log M^*_\text{ea}(N^n, \varepsilon) \geq nC_{\text{ea}}(N) + \sqrt{n}b + O(\log n). \tag{1.2}
\]

The coefficient \(b\) that we identify in this paper constitutes a second-order coding rate. The second-order coding rate obtained here depends on the channel as well as on the allowed error threshold \(\varepsilon\), and we obtain an explicit expression for it in Theorem \[\text{Hol02b}\]. In addition, we conjecture that in fact \(\log M^*_\text{ea}(N^n, \varepsilon) = nC_{\text{ea}}(N) + \sqrt{n}b + o(\sqrt{n})\). We show that this conjecture is true for the class of covariant channels \[\text{Hol02b}\].

Our lower bound on \(\log M^*_\text{ea}(N^n, \varepsilon)\) resembles the asymptotic expansion for the maximum number of bits of information which can be transmitted through \(n\) uses of a generic discrete, memoryless classical channel \(W\), with an average probability of error no larger than \(\varepsilon\), denoted \(\log M^*(W^n, \varepsilon)\). The latter was first derived by Strassen in 1962 \[\text{Str62}\] and refined by Hayashi \[\text{Hay09}\] as well as Polyanskiy, Poor and Verdú \[\text{PPY10}\]. It is given by

\[
\log M^*(W^n, \varepsilon) = nC(W) + \sqrt{nV_e(W)} \Phi^{-1}(\varepsilon) + o(\sqrt{n}), \tag{1.3}
\]

\(^1\)In other words, the channel is assumed to be memoryless.
where $\mathcal{W}^n$ denotes $n$ uses of the channel, $C(\mathcal{W})$ is its capacity given by Shannon’s formula \cite{Sha48}, $\Phi^{-1}$ is the inverse of the cumulative distribution function of a standard normal random variable, and $V_\varepsilon(\mathcal{W})$ is a property of the channel (which depends on $\varepsilon$) called its $\varepsilon$-dispersion \cite{PPV10}. The right hand side of (1.3) is called the Gaussian approximation of $\log M^*(\mathcal{W}^n, \varepsilon)$. This result has recently been generalized to classical coding for quantum channels \cite{TT13} and it was shown that a formula reminiscent of (1.3) also holds for the classical capacity of quantum channels with product inputs. In fact, the Gaussian approximation is a common feature of the second-order asymptotics for optimal rates of many other quantum information processing tasks such as data compression, communication, entanglement manipulation and randomness extraction (see, e.g., \cite{TH13,KH13,TT13,DL14} and references therein).

Finally, we note that a one-shot lower bound on $M^*_\text{ea}(\mathcal{N}, \varepsilon)$ has already been derived in \cite{DH13}. Moreover, in \cite{MW12} a one-shot upper bound was obtained. Even though these bounds converge in first order to the formula for the capacity obtained by Bennett et al. \cite{BSST02}, neither of these works deals with identifying the second-order asymptotics.

This paper is organized as follows. Section 2 introduces the necessary notation and definitions. Section 3 presents our main theorem and our conjecture. The proof of the theorem is given in Section 4. In this section, we also provide a proof of our conjecture for the case of covariant channels. We end with a discussion of open questions in Section 5, summarizing the problems encountered when trying to prove the converse for general channels.

### 2 Notations and Definitions

Let $\mathcal{B}(\mathcal{H})$ denote the algebra of linear operators acting on a finite-dimensional Hilbert space $\mathcal{H}$. Let $\mathcal{P}(\mathcal{H}) \subset \mathcal{B}(\mathcal{H})$ be the set of positive semi-definite operators, and let $\mathcal{D}(\mathcal{H}) \subset \mathcal{P}(\mathcal{H})$ denote the set of quantum states (density matrices), $\mathcal{D}(\mathcal{H}) := \{\rho \in \mathcal{P}(\mathcal{H}) : \text{Tr} \rho = 1\}$. We denote the dimension of a Hilbert space $\mathcal{H}_A$ by $|A|$ and write $\mathcal{H}_A \simeq \mathcal{H}_{A'}$ when $\mathcal{H}_A$ and $\mathcal{H}_{A'}$ are isomorphic, i.e., if $|A| = |A'|$. A quantum state $\psi$ is called pure if it is rank one; in this case, we associate with it an element $|\psi\rangle \in \mathcal{H}$ such that $\psi = |\psi\rangle \langle \psi|$. The set of pure quantum states is denoted $\mathcal{D}_p(\mathcal{H})$.

For a bipartite operator $\omega_{AB} \in \mathcal{B}(\mathcal{H}_A \otimes \mathcal{H}_B)$, let $\omega_A := \text{Tr}_B \omega_{AB}$ denote its restriction to the subsystem $A$, where $\text{Tr}_B$ denotes the partial trace over $B$. Let $I_A$ denote the identity operator on $\mathcal{H}_A$, and let $\pi_A := I_A/|A|$ be the completely mixed state in $\mathcal{D}(\mathcal{H}_A)$.

A positive operator-valued measure (POVM) is a set $\{\Lambda^x_A\}_{x \in \mathcal{X}} \subset \mathcal{P}(\mathcal{H}_A)$ such that $\sum_{x \in \mathcal{X}} \Lambda^x_A = I_A$, where $\mathcal{X}$ denotes any index set. We use the convention that $\mathcal{E}_{A \to B}$ refers to a completely positive trace-preserving (CPTP) map $\mathcal{E}_{A \to B} : \mathcal{B}(\mathcal{H}_A) \to \mathcal{B}(\mathcal{H}_B)$. We call such maps quantum channels in the following. The identity map on $\mathcal{B}(\mathcal{H}_A)$ is denoted $\text{id}_A$.

We employ the cumulative distribution function for a standard normal random variable:

$$\Phi(a) := \frac{1}{\sqrt{2\pi}} \int_{-\infty}^{a} dx \exp \left( -\frac{x^2}{2} \right). \tag{2.1}$$

and its inverse $\Phi^{-1}(\varepsilon) := \sup \{a \in \mathbb{R} \mid \Phi(a) \leq \varepsilon\}$.

### 2.1 Entanglement-Assisted Codes

We consider entanglement-assisted classical (EAC) communication through a noisy quantum channel, given by a CPTP map $\mathcal{N}_{A \to B}$. The sender (Alice) and the receiver (Bob) initially share an
arbitrary pure state $|\varphi_{A'B'}\rangle$, where without loss of generality we assume that $\mathcal{H}_{A'} \simeq \mathcal{H}_{B'}$, the system $A'$ being with Alice and the system $B'$ with Bob. The goal is to transmit classical messages from Alice to Bob, labelled by the elements of an index set $\mathcal{M}$, through $\mathcal{N}_{A\to B}$.

Without loss of generality, any EAC communication protocol can be assumed to have the following form: Alice encodes her classical messages into states of the system $A$. Let the encoding CPTP map corresponding to message $m \in \mathcal{M}$ be denoted by $\mathcal{E}_{A'\to A}^m$. Alice then sends the system $A$ through $\mathcal{N}_{A\to B}$ to Bob. Subsequently, Bob performs a POVM $\{\Lambda_{BB'}^m\}_{m \in \mathcal{M}}$ on the system $BB'$ in his possession. This yields a classical register $\hat{M}$ which contains his inference $m \in \mathcal{M}$ of the message sent by Alice.

The above defines an EAC code for the quantum channel $\mathcal{N}_{A\to B}$, which consists of a quadruple

$$\mathcal{C} = \{\mathcal{M}, |\varphi_{A'B'}\rangle, \{\mathcal{E}_{A'\to A}^m\}_{m \in \mathcal{M}}, \{\Lambda_{BB'}^m\}_{m \in \mathcal{M}}\}. \quad (2.2)$$

The size of a code is denoted as $|\mathcal{C}| = |\mathcal{M}|$. The average probability of error for $\mathcal{C}$ on $\mathcal{N}_{A\to B}$ is

$$p_{\text{err}}(\mathcal{N}_{A\to B}, \mathcal{C}) := \Pr[M \neq \hat{M}] = 1 - \frac{1}{|\mathcal{M}|} \sum_m \text{Tr} \left( \Lambda_{BB'}^m \mathcal{N}_{A\to B} \otimes \text{id}_{B'} \left(\mathcal{E}_{A'\to A}^m \otimes \text{id}_{B'} (|\varphi_{A'B'}\rangle\rangle)\right) \right). \quad (2.3)$$

The following quantity describes the maximum size of an EAC code for transmitting classical information through a single use of $\mathcal{N}_{A\to B}$ with average probability of error at most $\varepsilon$.

**Definition 1.** Let $\varepsilon \in (0, 1)$ and $\mathcal{N} \equiv \mathcal{N}_{A\to B}$ be a quantum channel. We define

$$M_{ea}^*(\mathcal{N}, \varepsilon) := \max \{ m \in \mathbb{N} \mid \exists \mathcal{C} : |\mathcal{C}| = m \land p_{\text{err}}(\mathcal{N}, \mathcal{C}) \leq \varepsilon \}, \quad (2.4)$$

where $\mathcal{C}$ is a code as prescribed in (2.2).

We are particularly interested in the quantity $M_{ea}^*(\mathcal{N}^n, \varepsilon)$, where $n \in \mathbb{N}$ and $\mathcal{N}^n \equiv \mathcal{N}_{A_1 \to B_1} \otimes \ldots \otimes \mathcal{N}_{A_n \to B_n}$ is the $n$-fold memoryless repetition of $\mathcal{N}$.

### 2.2 Information Quantities

For a pair of positive semi-definite operators $\rho$ and $\sigma$ with $\text{supp } \rho \subseteq \text{supp } \sigma$, the quantum relative entropy and the relative entropy variance \cite{Linden2012, THORBJERG2013} are respectively defined as follows\footnote{All logarithms in this paper are taken to base two.}.

$$D(\rho||\sigma) := \text{Tr} \left[ \rho (\log \rho - \log \sigma) \right], \quad \text{and} \quad (2.5)$$

$$V(\rho||\sigma) := \text{Tr} \left[ \rho (\log \rho - \log \sigma - D(\rho||\sigma))^2 \right]. \quad (2.6)$$

For a bipartite state $\rho_{AB}$, let us define the mutual information $I(A : B)_\rho := D(\rho_{AB}||\rho_A \otimes \rho_B)$. Similarly, we define the mutual information variance $V(A : B)_\rho := V(\rho_{AB}||\rho_A \otimes \rho_B)$.

The EAC capacity of a quantum channel $\mathcal{N}$ is defined as

$$C_{ea}(\mathcal{N}) := \lim_{\varepsilon \to 0} \lim_{n \to \infty} \frac{1}{n} \log M_{ea}^*(\mathcal{N}^n, \varepsilon). \quad (2.7)$$
Bennett, Shor, Smolin and Thapliyal [BSST02] established that the EAC capacity for a quantum channel \( N \equiv N_{A\rightarrow B} \) satisfies
\[
C_{ea}(N) = \max_{\psi_{AA'}} I(A': B)_\omega, \quad \text{where} \quad \omega_{A'B} = N_{A\rightarrow B} \otimes \text{id}_{A'}(\psi_{AA'}),
\] (2.8)
where the maximum is taken over all \( \psi_{AA'} \in \mathcal{D}_*(\mathcal{H}_A \otimes \mathcal{H}_{A'}) \) with \( \mathcal{H}_{A'} \simeq \mathcal{H}_A \). Its proof was later simplified by Holevo [Hol02a], and an alternative proof was given in [HDW08].

In analogy with [TT13], the following definitions will be used to characterize the second-order asymptotic behavior of \( M_{ea}^*(N^n, \varepsilon) \) for large \( n \).

**Definition 2.** Let \( N \equiv N_{A\rightarrow B} \) be a quantum channel. The set of capacity achieving resource states on \( N \) is defined as
\[
\Pi(N) := \arg \max_{\psi_{AA'}} I(A': B)_\omega \subseteq \mathcal{D}_*(\mathcal{H}_A \otimes \mathcal{H}_{A'}),
\] (2.9)
where \( \omega_{A'B} \) is given in (2.8). The minimal mutual information variance and the maximal mutual information variance of \( N \) are respectively defined as
\[
V_{ea,\min}(N) := \min_{\psi_{AA'}} V(A': B)_\omega \quad \text{and} \quad V_{ea,\max}(N) := \max_{\psi_{AA'}} V(A': B)_\omega,
\] (2.10)
where the optimizations are over \( \psi_{AA'} \in \Pi(N) \) and \( \omega_{A'B} \) is given in (2.8).

### 3 Results

We have conclusive results concerning the achievability of the second-order coding rate.

**Theorem 3.** Let \( \varepsilon \in (0, 1) \) and let \( N \equiv N_{A\rightarrow B} \) be a quantum channel. Then,
\[
\log M_{ea}^*(N^n, \varepsilon) \geq \begin{cases} 
nC_{ea}(N) + \sqrt{nV_{ea,\min}(N)} \Phi^{-1}(\varepsilon) + K(n; N, \varepsilon) & \text{if } \varepsilon < \frac{1}{2} \\
nC_{ea}(N) + \sqrt{nV_{ea,\max}(N)} \Phi^{-1}(\varepsilon) + K(n; N, \varepsilon) & \text{else}
\end{cases}
\] (3.1)
where \( K(n; N, \varepsilon) = O(\log n) \).

The proof of Theorem 3 is split into two parts, Proposition [11] in Section 4.2 and Proposition [13] in Section 4.3. We first derive a one-shot lower bound on \( \log M_{ea}^*(N, \varepsilon) \) using a coding scheme that is a one-shot version of the coding scheme given in [HDW08] and reviewed in [Wil13, Sec. 20.4]. Our one-shot bound is expressed in terms of an entropic quantity called the hypothesis testing relative entropy [WR12] (see Section 4.1 for a definition). An asymptotic expansion for this quantity for product states was derived independently by Tomamichel and Hayashi [TH13] and Li [Li12], and we make use of this to obtain our lower bound on \( \log M_{ea}^*(N^n, \varepsilon) \) in the second step.

**Remark 4.** In particular, Theorem 3 establishes that
\[
\liminf_{n \to \infty} \frac{1}{\sqrt{n}} \left( \log M_{ea}^*(N^n, \varepsilon) - nC_{ea}(N) \right) \geq \begin{cases} 
\sqrt{V_{ea,\min}(N)} \Phi^{-1}(\varepsilon) & \text{if } \varepsilon < \frac{1}{2} \\
\sqrt{V_{ea,\max}(N)} \Phi^{-1}(\varepsilon) & \text{else}
\end{cases}
\] (3.2)
In analogy with [PPV10, Eq. (221)] and [TT13, Rm. 3], we define the EAC ε-channel dispersion, for ε ∈ (0, 1) \ \{ \frac{1}{2} \} as
\[ V_{ea,\varepsilon}(\mathcal{N}) := \limsup_{n \to \infty} \frac{1}{n} \left( \log M_{ea}^* (N^n, \varepsilon) - nC_{ea}(\mathcal{N}) \right)^2. \] (3.3)

Theorem 3 shows that \( V_{ea,\varepsilon}(\mathcal{N}) \leq V_{ea,\min}(\mathcal{N}) \) if \( \varepsilon < \frac{1}{2} \) and \( V_{ea,\varepsilon}(\mathcal{N}) \geq V_{ea,\max}(\mathcal{N}) \) if \( \varepsilon > \frac{1}{2} \).

This leads us to the following conjecture:

**Conjecture 5.** We conjecture that \( (3.1) \) is an equality with \( K(n; N, \varepsilon) = o(\sqrt{n}) \). In particular, we conjecture that the EAC ε-channel dispersion satisfies
\[ V_{ea,\varepsilon}(\mathcal{N}) = \begin{cases} V_{ea,\min}(\mathcal{N}) & \text{if } \varepsilon < \frac{1}{2} \\ V_{ea,\max}(\mathcal{N}) & \text{else} \end{cases} \] (3.4)
and, thus, \( \log M_{ea}^* (N^n, \varepsilon) = nC_{ea}(\mathcal{N}) + \sqrt{nV_{ea,\varepsilon}(\mathcal{N})} \Phi^{-1}(\varepsilon) + o(\sqrt{n}) \).

We show that Conjecture 5 is true for the class of covariant quantum channels. This follows essentially from an analysis by Matthews and Wehner [MW12] which we recapitulate in Section 4.4 and the asymptotic expansion of the hypothesis testing relative entropy.

4 Proofs

4.1 Technical Preliminaries

For given orthonormal bases \( \{|i_A\rangle\}_{i=1}^d \) and \( \{|i_B\rangle\}_{i=1}^d \) in isomorphic Hilbert spaces \( \mathcal{H}_A \simeq \mathcal{H}_B \simeq \mathcal{H} \) of dimension \( d \), we define a maximally entangled state of Schmidt rank \( d \) to be
\[ |\Phi_{AB}\rangle := \frac{1}{\sqrt{d}} \sum_{i=1}^d |i_A\rangle \otimes |i_B\rangle. \] (4.1)

Note that if \( d = 1 \) then \(|\Phi_{AB}\rangle\) is a product state. We often make use of the following identity ("transpose trick"): for any operator \( M \),
\[ (M_A \otimes I_B)|\Phi_{AB}\rangle = (I_A \otimes M_B^T)|\Phi_{AB}\rangle, \] (4.2)
where \( M_B^T := \sum_{i,j=1}^d |i\rangle_B \langle j|_B M_A |i\rangle_A \langle j|_B \) denotes the transpose.

4.1.1 Distance Measures

The trace distance between two states \( \rho \) and \( \sigma \) is given by
\[ \frac{1}{2} \| \rho - \sigma \|_1 = \max_{0 \leq Q \leq I} \text{Tr} (Q (\rho - \sigma)) = \text{Tr} [ \{ \rho \geq \sigma \} (\rho - \sigma) ] \] (4.3)
where \( \{ \rho \geq \sigma \} \) denotes the projector onto the subspace where the operator \( \rho - \sigma \) is positive semi-definite. The fidelity of \( \rho \) and \( \sigma \) is defined as
\[ F(\rho, \sigma) := \| \sqrt{\rho} \sqrt{\sigma} \|_1. \] (4.4)

For a pair of pure states \( \phi \) and \( \psi \), the trace distance and fidelity satisfy the following relation:
\[ \frac{1}{2} \| \phi - \psi \|_1 = \sqrt{1 - F^2(\phi, \psi)}. \] (4.5)
4.1.2 Relative Entropies for One-Shot Analysis

We will phrase our one-shot bounds in terms of the following relative entropy.

**Definition 6.** Let \( \varepsilon \in (0,1) \), \( \rho \in \mathcal{D}(\mathcal{H}) \) and \( \sigma \in \mathcal{P}(\mathcal{H}) \). Then, the hypothesis testing relative entropy [WR12] is defined as

\[
D^\varepsilon_H(\rho\|\sigma) := -\log \beta^\varepsilon(\rho\|\sigma), \tag{4.6}
\]

where

\[
\beta^\varepsilon(\rho\|\sigma) := \min\{ \text{Tr}(Q\sigma) : 0 \leq Q \leq I, \text{Tr}(Q\rho) \geq 1 - \varepsilon \}. \tag{4.7}
\]

Note that when \( \sigma \in \mathcal{D}(\mathcal{H}) \), \( \beta^\varepsilon(\rho\|\sigma) \) has an interpretation as the smallest type-II error of a hypothesis test between \( \rho \) and \( \sigma \), when the type-I error is at most \( \varepsilon \). The following lemma lists some properties of \( D^\varepsilon_H(\rho\|\sigma) \).

**Lemma 7.** Let \( \varepsilon \in (0,1) \). The hypothesis testing relative entropy has the following properties:

1. For any \( \rho \in \mathcal{D}(\mathcal{H}) \), \( \sigma' \geq \sigma \geq 0 \) we have \( D^\varepsilon_H(\rho\|\sigma) \geq D^\varepsilon_H(\rho\|\sigma') \).
2. For any \( \rho \in \mathcal{D}(\mathcal{H}) \), \( \sigma \geq 0 \), \( \alpha > 0 \), we have \( D^\varepsilon_H(\rho\|\alpha\sigma) = D^\varepsilon_H(\rho\|\sigma) - \log \alpha \).
3. For any classical-quantum state

\[
\rho_{XB} = \sum_{x \in \mathcal{X}} p(x)|x\rangle\langle x| \otimes \rho^x_B \in \mathcal{D}(\mathcal{H}_X \otimes \mathcal{H}_B), \tag{4.8}
\]

for any \( \sigma_X = \sum_{x \in \mathcal{X}} q(x)|x\rangle\langle x| \) (with \( \{p(x)\}_{x \in \mathcal{X}} \) and \( \{q(x)\}_{x \in \mathcal{X}} \) probability distributions on \( \mathcal{X} \)), and for any \( \sigma_B \in \mathcal{D}(\mathcal{H}_B) \), we have

\[
D^\varepsilon_H(\rho_{XB}\|\sigma_X \otimes \sigma_B) \geq \min_{x \in \mathcal{X}} D^\varepsilon_H(\rho^x_B\|\sigma_B), \tag{4.9}
\]

4. For any \( \delta \in (0,1-\varepsilon) \), \( \rho, \rho' \in \mathcal{D}(\mathcal{H}) \) with \( \frac{1}{2} \|\rho - \rho'\|_1 \leq \delta \), and \( \sigma \in \mathcal{P}(\mathcal{H}) \), we have \( D^\varepsilon_H(\rho\|\sigma) \leq D^\varepsilon_H(\rho'\|\sigma) \).

Properties 1–3 can be verified by close inspection and we omit their proofs.

**Proof of Property 4.** Consider \( Q \) to be the operator achieving the minimum in the definition of \( \beta^\varepsilon(\rho\|\sigma) \), i.e.

\[
D^\varepsilon_H(\rho'\|\sigma) = -\log \text{Tr}(Q\sigma) \quad \text{and} \quad \text{Tr}(Q\rho') \geq 1 - \varepsilon. \tag{4.10}
\]

From (4.3), we have \( \text{Tr}[Q(\rho' - \rho)] \leq \frac{1}{2} \|\rho - \rho'\|_1 \leq \delta \). Hence, \( \text{Tr}(Q\rho) \geq \text{Tr}(Q\rho') - \frac{1}{2} \|\rho - \rho'\|_1 \geq 1 - \varepsilon - \delta \), and

\[
D^\varepsilon_H(\rho'\|\sigma) \leq \max_{0 \leq Q' \leq I, \text{Tr}(Q'\rho) \geq 1 - \varepsilon - \delta} \left[ -\log \text{Tr}(Q'\sigma) \right] = D^{\varepsilon+\delta}_H(\rho\|\sigma), \tag{4.11}
\]

which concludes the proof. \( \square \)

The following result, established independently in [TH13, Eq. (34)] and [Li12], plays a central role in our analysis.
Lemma 8 (TH13). Let \( \varepsilon \in (0,1) \) and let \( \rho, \sigma \in \mathcal{D}(\mathcal{H}) \). Then,
\[
D_H^\varepsilon(\rho^{\otimes n}||\sigma^{\otimes n}) = nD(\rho||\sigma) + \sqrt{nV(\rho||\sigma)}\Phi^{-1}(\varepsilon) + O(\log n).
\] (4.12)

Two other generalized relative entropies which are relevant for our analysis are the collision relative entropy and the information-spectrum relative entropy [TH13]. For any pair of positive semi-definite operators \( \rho \) and \( \sigma \) satisfying the condition \( \text{supp} \rho \subseteq \text{supp} \sigma \), they are respectively defined as follows:
\[
D_2(\rho||\sigma) := \log \left( \text{Tr} \left( \sigma^{-1/4} \rho \sigma^{-1/4} \right)^2 \right),
\] (4.13)
and, for any \( \varepsilon \in (0,1) \),
\[
D_8^\varepsilon(\rho||\sigma) := \sup \{ R | \text{Tr} (\rho \{ \rho \leq 2^R \sigma \} ) \leq \varepsilon \}.
\] (4.14)
The following result, proved in [BG13, Thm. 4], relates these quantities.

Lemma 9 (BG13). Let \( \varepsilon, \lambda \in (0,1) \) and \( \rho, \sigma \in \mathcal{D}(\mathcal{H}) \). Then,
\[
2^{D_2(\rho||\lambda\rho+(1-\lambda)\sigma)} \geq (1-\varepsilon) \left[ \lambda + (1-\lambda)2^{-D_8^\varepsilon(\rho||\sigma)} \right]^{-1}.
\] (4.15)

Finally, the following lemma provides a useful relation between the hypothesis testing relative entropy and the information spectrum relative entropy [TH13, Lm. 12].

Lemma 10 (TH13). Let \( \varepsilon \in (0,1), \delta \in (0,1-\varepsilon), \rho \in \mathcal{D}(\mathcal{H}), \) and \( \sigma \in \mathcal{P}(\mathcal{H}) \). Then,
\[
D_8^{\varepsilon+\delta}(\rho||\sigma) \geq D_H^\varepsilon(\rho||\sigma) + \log \delta.
\]

4.2 One-Shot Achievability

Consider a quantum channel \( \mathcal{N}_{A\to B} \) and introduce an auxiliary Hilbert space \( \mathcal{H}_{A'} \cong \mathcal{H}_A \). Let
\[
\mathcal{H}_A \otimes \mathcal{H}_{A'} = \bigoplus_t \mathcal{H}_A^t \otimes \mathcal{H}_{A'}^t, \quad \mathcal{H}_A^t \cong \mathcal{H}_{A'}^t
\] (4.16)
be a decomposition of \( \mathcal{H}_A \otimes \mathcal{H}_{A'} \), and set \( d_t = |\mathcal{H}_A^t| \). We assume that \( |\vartheta_{AA'}\rangle \) can be written as a superposition of maximally entangled states:
\[
|\vartheta_{AA'}\rangle = \sum_t \sqrt{p(t)} |\Phi^t\rangle, \quad (4.17)
\]
where \( |\Phi^t\rangle \) denotes a maximally entangled state of Schmidt rank \( d_t \) in \( \mathcal{H}_A^t \otimes \mathcal{H}_{A'}^t \) and \( p(t) \) is some probability distribution so that \( \sum_t p(t) = 1 \).

Proposition 11. Let \( \varepsilon \in (0,1), \delta \in (0,\frac{\varepsilon}{2}) \) and let \( \mathcal{N} \equiv \mathcal{N}_{A\to B} \) be a quantum channel. Then for any \( \vartheta_{AA'} \) of the form (4.17), we have
\[
\log M_{\text{ea}}^\varepsilon(\mathcal{N}, \varepsilon) \geq D_H^{\varepsilon+\delta}(\mathcal{N}_{A\to B}(\vartheta_{AA'})) - \sum_t p(t) \left( \mathcal{N}_{A\to B}(\pi_{A}^t) \otimes \pi_{A'}^t \right) - f(\varepsilon, \delta), \quad (4.18)
\]
where \( f(\varepsilon, \delta) := \log \frac{\delta}{\delta^2} \) and \( \pi_{A'}^t \) is the maximally mixed state on the space \( \mathcal{H}_{A'}^t \), with a similar convention for \( \pi_{A'}^t \).
Remark 12. Note that the hypothesis testing relative entropy on the right hand side is not reminiscent of a mutual information type quantity since the second argument is not a product state.

Proof. Consider the set
\[ \mathcal{S} := \{ (x_t, z_t, b_t) \mid x_t, z_t \in \{0, 1, \ldots, d_t - 1\}, b_t \in \{0, 1\} \}, \]
where the index \( t \) labels the Hilbert spaces of the decomposition in (4.10). For any \( s \in \mathcal{S} \), consider the following unitary operator in \( \mathcal{B}(\mathcal{H}_A) \):
\[ U_A(s) := \bigoplus_t (-1)^{b_t} X(x_t)Z(z_t), \]
where \( X(x_t) \) and \( Z(z_t) \) are the Heisenberg-Weyl operators defined in Appendix A.

For any \( M \in \mathbb{N} \), we now construct a random code as follows. Let \( \mathcal{M} = \{1, 2, \ldots, M\} \). We set \( A' \equiv A \) (i.e., we use the labels interchangeably), and \( \mathcal{H}_{BB'} \simeq \mathcal{H}_A \). We consider the resource state \( \varphi_{AB'} = \text{id}_{A' \to B'}(\varphi_{AA'}) \). For each message \( m \in \mathcal{M} \), choose a codeword, \( s_m \), uniformly at random from the set \( \mathcal{S} \). The encoding operation, \( \{\mathcal{E}_A^m\}_{m \in \mathcal{M}} \), is then given by the (random) unitary \( U(s_m) \) as prescribed above. In particular,
\[ \mathcal{E}_A^m \otimes \text{id}_{B'}(\varphi_{AB'}) = \phi_{AB'}^m, \quad \text{where} \quad |\phi_{AB'}^m \rangle := (U_A(s_m) \otimes I_{B'})|\varphi_{AB'} \rangle. \]

We denote the corresponding channel output state by \( \rho_{BB'}^m := \mathcal{N}_{A \to B}(\phi_{AB'}^m) \) and use “pretty good” measurements for decoding. These are given by the POVM \( \{\Lambda_{BB'}^m\}_{m \in \mathcal{M}} \), where
\[ \Lambda_{BB'}^m := \left( \sum_{m' \in \mathcal{M}} \rho_{BB'}^{s_{m'}} \right)^{-\frac{1}{2}} \rho_{BB'}^{s_m} \left( \sum_{m' \in \mathcal{M}} \rho_{BB'}^{s_{m'}} \right)^{-\frac{1}{2}}. \]

Let us now analyze the code \( \mathcal{C} = \{\mathcal{M}, \varphi_{AB'}, \{\mathcal{E}_A^m\}_{m \in \mathcal{M}}, \{\Lambda_{BB'}^m\}_{m \in \mathcal{M}}\} \) given by (4.21) and (4.22), where we recall that \( s_m \) is a random variable. For this purpose, consider the random state
\[ \sigma_{MSBB'} := \frac{1}{M} \sum_{m \in \mathcal{M}} \langle m | m \rangle_M \otimes | s_m \rangle \langle s_m |_S \otimes \rho_{BB'}^{s_m}. \]

Then, following Beigi and Gohari [BG13, Thm. 5], we find that the average probability of successfully inferring the sent message can be expressed as
\[ p_{\text{succ}}(\mathcal{C}, \mathcal{N}) := 1 - p_{\text{err}}(\mathcal{C}, \mathcal{N}) = \frac{1}{M} \sum_{m \in \mathcal{M}} \text{Tr}(\Lambda_{BB'}^m \rho_{BB'}^{s_m}) \]
\[ = \frac{1}{M} 2^{D_2(\sigma_{MSBB'} \parallel \sigma_{MS} \otimes \sigma_{BB'})}. \]

Moreover employing both the data-processing inequality and joint convexity of the collision relative entropy as in [BG13], we establish the following lower bound on the expected value of \( p_{\text{succ}} \) with respect to the randomly chosen codewords:
\[ \mathbb{E}(p_{\text{succ}}(\mathcal{C}, \mathcal{N})) \geq \frac{1}{M} 2^{D_2(\mathbb{E}(\sigma_{BB'}) \parallel \mathbb{E}(\sigma_S \otimes \sigma_{BB}))}. \]
Note that

\[ E(\sigma_S \otimes \sigma_{BB'}) = E \left( \frac{1}{M^2} \sum_{m \in M} |s_m\rangle \langle s_m| \otimes \rho_{BB'}^{s_m} \right) + E \left( \frac{1}{M^2} \sum_{m, m' \in M, m' \neq m} |s_m\rangle \langle s_m| \otimes \rho_{BB'}^{s_m} \right) \]  

\[ = \frac{1}{M} \rho_{BB'} + \left( 1 - \frac{1}{M} \right) \rho_S \otimes \rho_{BB'}, \]  

(4.27)

where

\[ \rho_{BB'} := E(\sigma_{BB'}) = N_{A \rightarrow B} \left( \frac{1}{|S|} \sum_{s \in S} |s\rangle \langle s| \otimes U_A(s) \varphi_{AB} U_A^\dagger(s) \right) \]  

\[ = \frac{1}{|S|} \sum_{s \in S} |s\rangle \langle s| \otimes N_{A \rightarrow B} \left( U_A(s) \varphi_{AB} U_A^\dagger(s) \right), \]  

(4.29)

and \( \rho_S \) and \( \rho_{BB'} \) are the corresponding reduced states on the systems \( S \) and \( BB' \), respectively. In particular, defining \( V(x_t, z_t) := X(x_t)Z(z_t) \), using the decomposition (4.17) of the state \( |\varphi_{AB}\rangle \) and the definition (4.20) of the unitary operators \( U_A(s) \), we find that

\[ \rho_{BB'} = N_{A \rightarrow B} \left( \frac{1}{|S|} \sum_{s \in S} U_A(s) \left( \sum_{t, t'} \sqrt{p(t)p(t')} |\Phi^t\rangle \langle \Phi^{t'}| \right) U_A^\dagger(s) \right) \]  

\[ = N_{A \rightarrow B} \left( \sum_{t} p(t) \frac{1}{d_t^2} \sum_{x_t, z_t = 0}^{d_t - 1} V(x_t, z_t) |\Phi^t\rangle \langle \Phi^{t'}| V^\dagger(x_t, z_t) \right) \]  

\[ + N_{A \rightarrow B} \left( \sum_{t, t' \neq t} \sqrt{p(t)p(t')} \frac{1}{4} \sum_{b_t, b_{t'} \in \{0, 1\}} (-1)^{b_t + b_{t'}} \frac{1}{d_t^2 d_{t'}^2} \sum_{x_t, z_t = 0}^{d_t - 1} \sum_{x_{t'}, z_{t'} = 0}^{d_{t'} - 1} V(x_t, z_t) |\Phi^t\rangle \langle \Phi^{t'}| V^\dagger(x_{t'}, z_{t'}) \right) \]  

(4.33)

can be written as the sum of a diagonal \( (t = t') \) and an off-diagonal \( (t \neq t') \) term. It can be easily verified (see, e.g., [Wil13, pp. 504–505]) that the off-diagonal term vanishes and in fact

\[ \rho_{BB'} = \sum_t p(t) N_{A \rightarrow B}(\pi_A^t) \otimes \pi_B^t, \]  

(4.34)

where \( \pi_A^t = \text{Tr}_{B'} \Phi^t \) and \( \pi_B^t = \text{Tr}_A \Phi^t \) are completely mixed states. The above identity follows from the fact that applying a Heisenberg-Weyl operator uniformly at random completely randomizes a quantum state, yielding a completely mixed state.

Hence, for any \( 0 < \delta < \varepsilon \), we have

\[ E \left( p_{\text{succ}}(C, \mathcal{N}) \right) \geq \frac{1}{M} 2D_2(\rho_{BB'}||\frac{1}{M} \rho_{BB'} + (1 - \frac{1}{M})(\rho_S \otimes \rho_{BB'})) \]

\[ \geq \frac{1 - (\varepsilon - \delta)}{1 + (M - 1) 2^{-D_2^2}(\rho_{BB'}||\rho_S \otimes \rho_{BB'})}, \]  

(4.35)

\[ (4.36) \]
where the last line follows from Lemma 9. Thus, provided that
\[ M \leq \frac{\delta}{1 - \varepsilon} 2^{D_{\varepsilon - \delta}^H (\rho_{SBB'} \| \rho_S \otimes \rho_{BB'})} + 1 \] (4.37)
the random code satisfies \( \mathbb{E} (p_{\text{succ}} (C, N)) \geq 1 - \varepsilon \). In particular, there exists a (deterministic) code which satisfies \( p_{\text{succ}} (C, N) \geq 1 - \varepsilon \). Hence, we conclude that
\[ \log M^*_{\text{ea}} (N, \varepsilon) \geq D_{\varepsilon - \delta}^H (\rho_{SBB'} \| \rho_S \otimes \rho_{BB'}) + \log \frac{\delta}{1 - \varepsilon} \] (4.38)
\[ \geq D_{\varepsilon - 2\delta}^H (\rho_{SBB'} \| \rho_S \otimes \rho_{BB'}) - f (\varepsilon, \delta), \] (4.39)
where we require that \( \varepsilon > 2\delta \) and use
\[ f (\varepsilon, \delta) = \log \frac{1 - \varepsilon}{\delta}. \] (4.40)
The inequality in (4.39) follows from Lemma 10. Further, since \( \rho_{SBB'} \) is a classical-quantum state as seen in (4.30), by item 3 of Lemma 7 we have
\[ D_{\varepsilon - 2\delta}^H (\rho_{SBB'} \| \rho_S \otimes \rho_{BB'}) \geq \min_{s \in S} D_{\varepsilon - 2\delta}^H (\rho_{sBB'} \| \rho_{BB'}), \] (4.41)
where
\[ \rho_{sBB'} = N_{A \rightarrow B} \left( U_A (s) \varphi_{AB'} U_A^\dagger (s) \right). \] (4.42)
Using the decomposition (4.17) of the state \( |\varphi_{AB'} \rangle \) and the transpose trick (4.2) we can write
\[ \rho_{sBB'} = U^T_B (s) N_{A \rightarrow B} (\varphi_{AB'}) U^T_B^\dagger (s). \] (4.43)
Further, from (4.34) it follows that
\[ U^T_B (s) \rho_{BB'} U^T_B^\dagger (s) = \rho_{BB'}. \] (4.44)
Hence, (4.43), (4.44), and the invariance of the hypothesis testing relative entropy under the same unitary on both states imply that
\[ D_{\varepsilon - 2\delta}^H (\rho_{sBB'} \| \rho_{BB'}) = D_{\varepsilon - 2\delta}^H \left( N_{A \rightarrow B} (\varphi_{AB'}) \left\| \sum_t p (t) \left( N_{A \rightarrow B} (\pi^t_A) \otimes \pi^t_{B'} \right) \right\right). \] (4.45)
From (4.39) and (4.45) we obtain the statement of the proposition.

Remark 13. Alternatively, one may also employ the one-shot achievability result of Hayashi and Nagaoka [HN03] (in the form of [WR12]), which leads to the following bound on the one-shot \( \varepsilon \)-error entanglement-assisted capacity. Let \( \varepsilon \in (0, 1) \). Then, for any \( \delta \in (0, \varepsilon) \) and for any \( |\vartheta_{AA'} \rangle \) with decomposition (4.17), we have
\[ \log M^*_{\text{ea}} (N, \varepsilon) \geq D_{\varepsilon - \delta}^H \left( N_{A \rightarrow B} (\vartheta_{AA'}) \left\| \sum_t p (t) \left( N_{A \rightarrow B} (\pi^t_A) \otimes \pi^t_{A'} \right) \right\right) - \log \frac{4e}{\delta^2}. \] (4.46)
The proof of this lower bound uses the same coding scheme as given above while employing the error analysis and decoder given in [HN03].
4.3 Second Order Analysis for Achievability

Theorem 3 is a direct corollary of the following result, for an appropriate choice of $\psi_{AA'}$.

**Proposition 14.** Let $\varepsilon \in (0,1)$, $N \equiv N_{A \rightarrow B}$ be a quantum channel, and $\psi_{AA'} \in D_{\ast}(\mathcal{H}_A \otimes \mathcal{H}'_A)$, where $\mathcal{H}_A \simeq \mathcal{H}_A$. Then, we have

$$
\log M_{\text{es}}(N^n, \varepsilon) \geq n I(A' : B)_{\omega} + \sqrt{n V(A' : B)_{\omega}} \Phi^{-1}(\varepsilon) + K(n; N, \varepsilon, \psi_{AA'}),
$$

(4.47)

where $\omega_{A'B} = N_{A \rightarrow B} \otimes \text{id}_{A'}(\psi_{AA'})$ and $K(n; N, \varepsilon, \psi_{AA'}) = O(\log n)$.

**Proof.** We intend to apply Proposition 11 to the channel $N^n := N^\otimes n$ for a fixed $n$. For this purpose, let us first construct an appropriate resource state $\vartheta_{A^nA'^n}$. We write

$$
|\psi_{AA'}\rangle = \sum_{x \in \mathcal{X}} \sqrt{q(x)} |x\rangle_A \otimes |x\rangle_{A'}
$$

(4.48)

in its Schmidt decomposition, where $\mathcal{X} = \{1, 2, \ldots, d\}$ with $d = \dim_{A} = \dim_{A'}$ and define $\rho_{A'} = \text{Tr}_A \psi_{AA'}$. For a sequence $x^n = (x_1, x_2, \ldots, x_n) \in \mathcal{X}^n$, we write $|x^n\rangle_{A^n} = |x_1\rangle_A \otimes |x_2\rangle_A \otimes \cdots \otimes |x_n\rangle_{A_n}$. We denote type classes (for sequences of length $n$) by $\mathcal{T}$, i.e., $\mathcal{T} = \{x^n \in \mathcal{X}^n : P_{x^n} = t\}$ where $P_{x^n}$ denotes the empirical distribution of the sequence $x^n \in \mathcal{X}^n$. The set of empirical distributions is denoted $\mathcal{P}_n$. (We refer to Appendix B for a short overview of the method of types and relevant results.) We consider the decomposition

$$
(\mathcal{H}_A \otimes \mathcal{H}_{A'})^{\otimes n} = \bigoplus_{t \in \mathcal{P}_n} \mathcal{H}_{A^n}^t \otimes \mathcal{H}_{A'^n}^t,
$$

(4.49)

where $\mathcal{H}_{A^n}^t = \text{span}\{|x^n\rangle_{A^n} | x^n \in \mathcal{T}^t\}$ as in (4.16). Notably, since $\psi_{AA'}^\otimes$ is a tensor-power state, we can write

$$
|\psi_{AA'}^\otimes\rangle = \sum_{t \in \mathcal{P}_n} \sqrt{p'(t)} |\Phi^t\rangle,
$$

(4.50)

where $|\Phi^t\rangle \in \mathcal{H}_{A^n}^t \otimes \mathcal{H}_{A'^n}^t$ denotes a maximally entangled state of Schmidt rank $d_t = |\mathcal{T}^t|$, and

$$
p'(t) := \sum_{x^n \in \mathcal{T}^t} q^n(x^n), \quad \text{where} \quad q^n(x^n) = \prod_{i=1}^{n} q(x_i).
$$

(4.51)

Now, fix a small $\mu > 0$ and consider a restriction of $|\psi_{AA'}^\otimes\rangle$ to types $\mu$-close to $q$. More precisely, we consider the set $\mathcal{P}_n^{\mu} := \{t \in \mathcal{P}_n | D(t||q) \leq \mu\}$ and define

$$
|\vartheta_{A^nA'^n}\rangle := \sum_{t \in \mathcal{P}_n^{\mu}} \sqrt{p(t)} |\Phi^t\rangle,
$$

(4.52)

where $p(t) = \frac{p'(t)}{\alpha}$, and

$$
\alpha := \sum_{t \in \mathcal{P}_n^{\mu}} p(t) = \sum_{t \in \mathcal{P}_n^{\mu}} \frac{p'(t)}{\alpha} \geq 1 - 2^{-n \left(\frac{\mu}{\log(n+1)}\right)}.
$$

(4.53)

where the last inequality follows from (B.6) in Appendix B. Note that

$$
\frac{1}{2} \left\| \vartheta_{A'^nB'^n} - \psi_{AA'}^\otimes \right\|_1 \leq \sqrt{1 - F^2(\vartheta_{A'^nB'^n}, \psi_{AA'}^\otimes)} = \sqrt{1 - \alpha} = 2^{-\frac{n}{2} \left(\frac{\mu}{\log(n+1)}\right)} = g(n, \mu),
$$

(4.54)

(4.55)
where the last inequality follows from \eqref{4.53}.

Next, recall that $N^n \equiv (N_{A \rightarrow B})^{\otimes n}$. Then by Proposition \[ \text{ fixed } \varepsilon > 0 \text{ and } 0 < 2\delta < \varepsilon \]
and $\partial A^n A^m$ given in \eqref{4.52}, we establish that

\[
\log M_{\epsilon \alpha}(N^n, \varepsilon) \geq D^H_{H} - 2\delta \left( N^n \left( \partial A^n A^m \right) \left( \sum_{t \in P_{n}^{\theta}} p(t) \left( N^n(\pi^t_{A^n}) \otimes \gamma_{n,m} \rho^{\otimes n}_{A'} \right) - f(\varepsilon, \delta) \right) \right) (4.56)
\]

where $f(\varepsilon, \delta)$ is given by \eqref{4.40}, and $\pi^t_{A^n}$ and $\pi^t_{A^m}$ are completely mixed states. In particular, for any $t$ with $D(t||q) \leq \mu$, we have

\[
\pi^t_{A^n} = \frac{1}{d_t} \sum_{x^n \in T^t} |x^n\rangle \langle x^n| \leq (n + 1)|X| q_{\theta} \sum_{x^n \in T^t} q^n(x^n) |x^n\rangle \langle x^n| \leq (n + 1)|X| q_{\theta} \sum_{x^n \in X^n} q^n(x^n) |x^n\rangle \langle x^n| = \gamma_{n,m} \rho^{\otimes n}_{A'} .
\]

The first inequality in \eqref{4.58} follows from \eqref{4.5} in Appendix B which is a consequence of the fact that $D(t||q) \leq \mu$.

Next, we use \eqref{4.56} and \eqref{4.58} to obtain

\[
\log M_{\epsilon \alpha}(N^n, \varepsilon) \geq D^H_{H} - 2\delta \left( N^n \left( \partial A^n A^m \right) \left( \sum_{t \in P_{n}^{\theta}} p(t) \left( N^n(\pi^t_{A^n}) \otimes \gamma_{n,m} \rho^{\otimes n}_{A'} \right) - f(\varepsilon, \delta) \right) \right) (4.59)
\]

\[
= D^H_{H} - 2\delta \left( N^n \left( \partial A^n A^m \right) \left( \sum_{t \in P_{n}^{\theta}} p(t) \left( N^n(\pi^t_{A^n}) \otimes \rho^{\otimes n}_{A'} \right) - f(\varepsilon, \delta) - \log \gamma_{n,m} \right) \right) (4.60)
\]

\[
\geq D^H_{H} - 2\delta - g(n, \mu) \left( (N(\psi_{A'A'})^{\otimes n}) \left( \sum_{t \in P_{n}^{\theta}} p(t) N^n(\pi^t_{A^n}) \otimes \rho^{\otimes n}_{A'} \right) - f(\varepsilon, \delta) - \log \gamma_{n,m} \right) (4.61)
\]

\[
\geq D^H_{H} - 2\delta - g(n, \mu) \left( (N(\psi_{A'A'})^{\otimes n}) \left( \sum_{t \in P_{n}^{\theta}} p(t) N^n(\pi^t_{A^n}) \otimes \rho^{\otimes n}_{A'} \right) - f(\varepsilon, \delta) - \log \gamma_{n,m} \right) (4.62)
\]

\[
= D^H_{H} - 2\delta - g(n, \mu) \left( (N(\psi_{A'A'})^{\otimes n}) \left( \sum_{t \in P_{n}^{\theta}} p(t) N^n(\pi^t_{A^n}) \otimes \rho^{\otimes n}_{A'} \right) - f(\varepsilon, \delta) - \log \gamma_{n,m} \right) (4.63)
\]

The first and second lines follow from items 1 and 2 of Lemma \[ \text{ respectively. The third line follows from item 4 of Lemma \[ \text{ The fourth line also follows from item 2 of Lemma \[ since \]

\[
\sum_{t \in P_{n}^{\theta}} p(t) N^n(\pi^t_{A^n}) \otimes \rho^{\otimes n}_{A'} \geq \sum_{t \in P_{n}^{\theta}} p(t) N^n(\pi^t_{A^n}) \otimes \rho^{\otimes n}_{A'} .
\]

The last line follows from the linearity of $N^n$ and the fact that

\[
\sum_{t \in P_{n}^{\theta}} p(t) \pi^t_{A^n} = \text{Tr}_{A^n} \psi_{A'A'} = \rho^{\otimes n}_{A} .
\]

Let us choose $\delta = 1/\sqrt{n}$ and $\mu = (|X| + 1) \log(n + 1) / n$. Then

\[
g(n, \mu) = \frac{1}{\sqrt{n}} \leq \frac{1}{\sqrt{n}} , \quad \text{ and } \quad \varepsilon - 2\delta - g(n, \mu) \geq \varepsilon - 3/\sqrt{n} .
\]
Since $D_H^\varepsilon(\rho\|\sigma) \geq D_H^{\varepsilon'}(\rho\|\sigma)$ for $\varepsilon > \varepsilon'$, we obtain the following bound from (4.61):

$$
\log M^*_{ea}(N^n, \varepsilon) \geq D_H^{3/\sqrt{n}}( (N(\psi_{AA'}))^\otimes n) \left\| (N(\rho_A))^\otimes n \otimes \rho_{A'}^{\otimes n} \right\| - f(\varepsilon, \delta) - \log \gamma_{n,\mu},
$$

(4.68)

thus arriving at an expression involving the hypothesis testing relative entropy for product states. Substituting the above choices for $\delta$ and $\mu$ in the expressions (4.40) for $f(\varepsilon, \delta)$ and in $\gamma_{n,\mu}$, we find that

$$
f(\varepsilon, \delta) + \log \gamma_{n,\mu} = O(\log n).
$$

(4.69)

Crucially, Lemma 8 applied to (4.68) now implies that

$$
\log M^*_{ea}(N^n, \varepsilon) \geq n D(N(\psi_{AA'}) \parallel N(\rho_A) \otimes \rho_{A'})
$$

(4.70)

$$
+ \sqrt{n} V(N(\psi_{AA'}) \parallel N(\rho_A) \otimes \rho_{A'}) \Phi^{-1}(\varepsilon - 3/\sqrt{n}) + K'(n; N, \varepsilon, \psi_{AA'})
$$

(4.71)

$$
= n I(A': B)_\omega + \sqrt{n} V(A': B)_\omega \Phi^{-1}(\varepsilon - 3/\sqrt{n}) + O(\log n)
$$

(4.72)

where $K'(n; N, \varepsilon, \psi_{AA'}) = O(\log n)$ due to (4.69). To conclude the proof, note that $\Phi^{-1}$ is continuously differentiable around $\varepsilon > 0$, and thus $\Phi^{-1}(\varepsilon - 3/\sqrt{n}) = \Phi^{-1}(\varepsilon) + O(1/\sqrt{n})$.

### 4.4 Second-Order Converse for Covariant Quantum Channels

In this section, we observe that the Gaussian approximation is valid for the entanglement-assisted capacity of covariant quantum channels (i.e., Conjecture 5 is true for this class of channels). Holevo first defined the class of covariant quantum channels [Hol02b], and it is now known that many channels fall within this class, including depolarizing channels, transpose depolarizing channels [WH02] [FHMV04], Pauli channels, cloning channels [Bra11], etc. Note that the following argument up to (4.82) has already essentially been proven in Section III-E of Matthews and Wehner [MW12]. However, we give a brief exposition in this section for completeness. We leave open the question of determining whether the Gaussian approximation is valid for the entanglement-assisted capacity of general discrete memoryless quantum channels.

Let $N_{A\rightarrow B}$ be a quantum channel mapping density operators acting on an input Hilbert space $\mathcal{H}_A$ to those acting on an output Hilbert space $\mathcal{H}_B$. Let $G$ be a compact group, and for every $g \in G$, let $g \rightarrow U_A(g)$ and $g \rightarrow V_B(g)$ be continuous projective unitary representations of $G$ in $\mathcal{H}_A$ and $\mathcal{H}_B$, respectively. Then the channel $N_{A\rightarrow B}$ is said to be covariant with respect to these representations if the following relation holds for all $g \in G$ and input density operators $\rho$:

$$
N_{A\rightarrow B} \left( U_A(g) \rho U_A^\dagger(g) \right) = V_B(g) N_{A\rightarrow B}(\rho) V_B^\dagger(g).
$$

(4.73)

We restrict our attention in this section to covariant channels for which the representation acting on the input space is irreducible.

In [MW12 Thm. 14], Matthews and Wehner establish the following upper bound on the one-shot entanglement-assisted capacity of a channel $N \equiv N_{A\rightarrow B}$.

$$
\log M^*_{ea}(N, \varepsilon) \leq \max_{\rho_A} \min_{\sigma_B} D_H( N(\phi_{AA'}^\rho) \parallel \rho_{A'} \otimes \sigma_B),
$$

(4.74)
where $\phi_{AA'}^\rho$ is a purification of $\rho_A$ and $\rho_{A'}$ is the reduction of $\phi_{AA'}^\rho$ to $A'$. They also prove [MW12 Thm. 19] that the quantity $\beta_\varepsilon (\mathcal{N}_{A\rightarrow B} (\phi_{AA'}^\rho) \parallel \rho_{A'} \otimes \sigma_B)$ is convex in the input density operator $\rho_A$ for any $\sigma_B$, from which it follows that the quantity

$$
\beta_\varepsilon (\mathcal{N}_{A\rightarrow B}, \rho_A) := \max_{\sigma_B} \beta_\varepsilon (\mathcal{N}_{A\rightarrow B} (\phi_{AA'}^\rho) \parallel \rho_{A'} \otimes \sigma_B)
$$

(4.75)

is convex in $\rho_A$ because it is the pointwise maximum of a set of convex functions.

We would now like to apply these results to the entanglement-assisted capacity of any discrete memoryless covariant channel $\mathcal{N}_{A^n\rightarrow B^n} \equiv \mathcal{N}^\otimes n$. By definition, such channels have the following covariance:

$$
\mathcal{N}_{A^n\rightarrow B^n} \left( (U_{A_1} (g_1) \otimes \cdots \otimes U_{A_n} (g_n)) \rho_{A^n} (U_{A_1} (g_1) \otimes \cdots \otimes U_{A_n} (g_n)) \right)
$$

$$
= [V_{B_1} (g_1) \otimes \cdots \otimes V_{B_n} (g_n)] \mathcal{N}_{A^n\rightarrow B^n} (\rho_{A^n}) [V_{B_1} (g_1) \otimes \cdots \otimes V_{B_n} (g_n)]^\dagger.
$$

(4.76)

Let $T_{A^n}$ be a shorthand for a sequence of local units of the form $U_{A_1} (g_1) \otimes \cdots \otimes U_{A_n} (g_n)$. Let $\mathbb{E}$ denote the expectation over all such units $T_{A^n}$, with the measure being the product Haar measure $\mu (g_1) \times \cdots \times \mu (g_n)$. Then following [MW12 Sec. III-E], we can conclude the following chain of inequalities:

$$
\beta_\varepsilon (\mathcal{N}_{A^n\rightarrow B^n}, \rho_{A^n}) = \mathbb{E} \left\{ \beta_\varepsilon (\mathcal{N}_{A^n\rightarrow B^n}, T_{A^n} \rho_{A^n} T_{A^n}^\dagger) \right\}
$$

(4.77)

$$
\geq \beta_\varepsilon (\mathcal{N}_{A^n\rightarrow B^n}, \mathbb{E} \left\{ T_{A^n} \rho_{A^n} T_{A^n}^\dagger \right\})
$$

(4.78)

$$
= \beta_\varepsilon (\mathcal{N}_{A^n\rightarrow B^n}, \pi_{A_1} \otimes \cdots \otimes \pi_{A_n}),
$$

(4.79)

where $\pi$ is the maximally mixed state. The first equality is a result of [MW12 Prop. 29] (this follows directly from the assumption of channel covariance with respect to the operations $T_{A^n}$). The sole inequality exploits convexity as mentioned above. The last equality follows because the state $\mathbb{E} \{ T_{A^n} \rho_{A^n} T_{A^n}^\dagger \}$ commutes with all local units $U_{A_1} (g_1) \otimes \cdots \otimes U_{A_n} (g_n)$. As a consequence of Schur’s lemma and the irreducibility of the representation on the input space, the only state which possesses such invariances is the tensor-power maximally mixed state. Note that we require irreducibility of the representation on only the input space in order for this argument to hold. So, by using the definition of $D^\varepsilon_H$, we can then conclude that

$$
\log M^*_{ca} (\mathcal{N}_{A^n\rightarrow B^n}, \varepsilon) \leq \max_{\rho_{A^n}, \sigma_{B^n}} \min_{\rho_{A^n}, \sigma_{B^n}} \beta_\varepsilon (\mathcal{N}_{A^n\rightarrow B^n} (\phi_{AA'}^\rho) \parallel \rho_{A^n} \otimes \sigma_{B^n})
$$

(4.80)

$$
\leq \min_{\sigma_{B^n}} \beta_\varepsilon ((\mathcal{N}_{A\rightarrow B} (\Phi_{AA'}))^\otimes n \parallel \pi_{A'}^\otimes n \otimes \sigma_{B^n})
$$

(4.81)

$$
\leq D^\varepsilon_H (\mathcal{N}_{A\rightarrow B} (\Phi_{AA'}))^\otimes n \parallel \pi_{A'}^\otimes n \otimes [\mathcal{N}_{A\rightarrow B} (\pi_A)]^\otimes n
$$

(4.82)

$$
= n I (A' : B) + \sqrt{n V (A' : B)} \Phi^{-1} (\varepsilon) + O (\log n)
$$

(4.83)

where the information quantities in the final line are with respect to the state $\omega_{A'B} := \mathcal{N}_{A\rightarrow B} (\Phi_{AA'})$. The final equality uses the asymptotic expansion in Lemma 8.

## 5 Discussion

We have established the direct part of the Gaussian approximation in Theorem 3 and conjectured that the converse also holds in Conjecture 5. In the following we will discuss some of the approaches taken and difficulties encountered when trying to prove the converse for general channels.
Arimoto Converse: Converse proofs using Arimoto’s approach \cite{Ari73} and quantum generalizations of the Rényi divergence \cite{MLDS13,WWY13} as in \cite{GW13} can be used to establish that the probability of successful decoding goes to zero exponentially fast for codes with \( \frac{1}{n} \log |M| > C_{ea} \). However, they only yield trivial results when \( \frac{1}{n} \log |M| = C_{ea} \pm O(1/\sqrt{n}) \), as is the case in the Gaussian approximation.

De Finetti Theorems: Following Matthews and Wehner \cite{MW12}, we find the following converse bound for \( n \) uses of the channel employing the arguments presented in Section 4.4 and (4.74).

\[
\log M_{ea}(N^n, \varepsilon) \leq \max_{\rho_{A^n}, \sigma_{B^n}} \min_{\rho_{A^n} \otimes \sigma_{B^n}} D_{\mathcal{H}}(N(\phi_{A^n A^n}^A) \| \rho_{A^n} \otimes \sigma_{B^n}),
\]

(5.1)

where \( \rho_{A^n} \) and \( \sigma_{B^n} \) are invariant under permutations of the \( n \) systems, and \( \phi_{A^n A^n}^A \) is chosen to have this property as well. One may now try to approximate the state \( \phi_{A^n A^n}^A \) by a convex combination of product states using the de Finetti theorem or the exponential de Finetti theorem \cite{Ren07}. However, the problem is that the number of systems that need to be sacrificed is at least of the order \( \sqrt{n} \), and thus affects the second order term significantly.

Relation to Channel Simulation: EAC coding is closely related to the classical communication cost in entanglement-assisted channel simulation \cite{BDH14} and \cite{BCR11}. In the latter paper, some bounds on the classical communication cost of entanglement-assisted channel simulation for a finite number of channels \( n \) are given. However, these bounds turn out to be unsuitable for our purposes since the error is scaled by a factor polynomial in \( n \) as a result of applying the post-selection technique \cite{CKR09}. It is not clear how the proof in \cite{BCR11} can be adapted to yield a statement for fixed error.

We believe that establishing Conjecture 5 thus requires new techniques and that this constitutes an interesting open problem.

Acknowledgements. We are especially grateful to Milan Mosonyi for insightful discussions and for his help in establishing the proof of Propositions 11 and 14. We acknowledge discussions with Ke Li and Andreas Winter, and we thank the Isaac Newton Institute (Cambridge) for its hospitality while part of this work was completed. MT is funded by the Ministry of Education (MOE) and National Research Foundation Singapore, as well as MOE Tier 3 Grant “Random numbers from quantum processes” (MOE2012-T3-1-009). MMW acknowledges startup funds from the Department of Physics and Astronomy at LSU, support from the NSF through Award No. CCF-1350397, and support from the DARPA Quiness Program through US Army Research Office award W31P4Q-12-1-0019.

A Heisenberg-Weyl Operators

For any \( x, z \in \{0, 1, \cdots, d\} \) the Heisenberg-Weyl Operators \( X(x) \) and \( Z(z) \) are defined through their actions on the vectors of the qudit computational basis \( \{|j\rangle\}_{j \in \{0,1,\cdots,d-1\}} \) as follows:

\[
X(x)|j\rangle = |j \oplus x\rangle, \quad Z(z)|j\rangle = e^{2\pi i z j/d}|j\rangle,
\]

(A.1) (A.2)

where \( j \oplus x = (j + x) \mod d \). Also note that if \( d = 1 \), then both \( X(x) \) and \( Z(z) \) are equal to the identity operator.
B The Method of Types

In our proofs we employ the notion of types [Csi98], and hence we briefly recall certain relevant definitions and properties here.

Let $\mathcal{X}$ denote a discrete alphabet and fix $n \in \mathbb{N}$. The type (or empirical probability distribution) $P_x^n$ of a sequence $x^n \in \mathcal{X}^n$ is the empirical frequency of occurrences of each letter of $\mathcal{X}$, i.e., $P_x^n(a) := \frac{1}{n} \sum_{i=1}^{n} \delta_{x_i,a}$ for all $a \in \mathcal{X}$. Let $\mathcal{P}_n$ denote the set of all types. The number of types, $|\mathcal{P}_n|$, satisfies the bound [CT91, Thm. 11.1.1]

$$|\mathcal{P}_n| \leq (n+1)^{|\mathcal{X}|}. \quad (B.1)$$

For any type $t \in \mathcal{P}_n$, the type class $\mathcal{T}_t$ of $t$ is the set of sequences of type $t$, i.e.

$$\mathcal{T}_t := \{x^n \in \mathcal{X}^n : P_x^n = t\}. \quad (B.2)$$

The number of types in a type class $\mathcal{T}_t$ satisfies the following lower bound [Csi98, Lm. II.2]:

$$|\mathcal{T}_t| \geq 2^{nH(t) - (n+1)|\mathcal{X}|}. \quad (B.3)$$

where $H(t) := -\sum_{a \in \mathcal{X}} t(a) \log t(a)$, is the Shannon entropy of the type.

Let $q$ be any probability distribution on $\mathcal{X}$. For any sequence $x^n = (x_1, x_2, \ldots, x_n) \in \mathcal{X}^n$, let $q^n(x^n) = \prod_{i=1}^{n} q(x_i)$. Then, we have

$$q^n(x^n) = 2^{-n(H(t) + D(t\|q))}, \quad \text{where} \quad t = P_x^n \quad \text{(B.4)}$$

is the type of $x^n$ and $D(t\|q) := \sum_{a \in \mathcal{X}} t(a) \log \frac{t(a)}{q(a)}$ is the Kullback-Leibler divergence of the probability distributions $t$ and $q$. From (B.1), (B.3) and (B.4) it follows that for any sequence $x^n \in \mathcal{X}^n$ of type $t$,

$$(n+1)^{|\mathcal{X}|} 2^{nD(t\|q)} q^n(x^n) = 2^{-nH(t)} (n+1)^{|\mathcal{X}|} \geq \frac{1}{|\mathcal{T}_t|}. \quad (B.5)$$

Finally, for any $\mu > 0$ we have [CT91, Eq. (11.98)]

$$\sum_{x^n \in \mathcal{X}^n, D(P_x^n\|q) > \mu} q^n(x^n) \leq 2^{-n(\mu - |\mathcal{X}| \log(n+1))}. \quad (B.6)$$
