Stimulated by recent progress made by the LHCb Collaboration in discoveries of new bottom baryons, e.g., the $\Xi_b(6227)^-$ and the $\Sigma_b(6097)^\pm$, we re-examine the orbitally excited spectrum of the charmed and bottom baryons using Regge approach in the heavy quark-diquark picture. The results indicate that the spin-averaged mass spectrum of the orbitally-excited charmed and bottom baryons can be described by a linear Regge relation, which is derived from the rotating QCD string model. By giving further mass-splitting analysis of spin-dependent interactions, we explain the baryons $\Xi_b(6227)^-$ and the $\Sigma_b(6097)^\pm$, and the $\Sigma(2800)$ and $\Xi_c(2930)$ to be the $1P$-wave baryons, all with the spin-parity $J^P = 3/2^-$ preferably. Mass prediction of the bottom baryon $\Xi_b$ in its P- and D-waves are presented, providing clues for the coming experiments like the LHCb to find them.

I. INTRODUCTION

The information from singly heavy (SH) baryon spectrum is quite helpful to deepen the understanding of non-perturbative Quantum Chromodynamics (QCD) as the heavy quark inside a baryon endows us with a ‘flavor tag’ to look further into the nature of the interquark forces [1]. This forms an analogy with the hydrogen-like atoms, in which the quantum states of the binding systems are labeled well by that of light degrees of freedom, and provides us with a good chance to further construct excited states of the bottom baryon family. In the past two decades, more than twenty charmed baryon candidates have been announced by the different experimental collaborations [2]. Differing from the charmed baryons, searching for the bottom baryon states is far from easy for experiment since the bottom baryons seems to be more difficult to produce than the charmed baryons. Only several bottom baryon candidates were reported before 2017.

Recently, the LHCb Collaboration discovered, one after another, two new bottom baryon states, the $\Xi_b(6227)^-$ by studying its final states of the $\Lambda_b^0 K^-$ and $\Xi_b^0\pi^-$ [3], and the $\Sigma_b(6097)^\pm$ in the final states of $\Lambda_b^0\pi^\pm$ [4]. The two baryons differ about 130MeV in mass, close to the mass difference of $u/d$ and $s$ constituent quarks, and exhibit similar decay behaviors in width and final states. After their observations, the two baryons become the key states for establishing the whole family of the excited bottom baryons, and their properties and inner structures become hot topics for the heavy baryon study[5–11]. Most of these studies prefer to suggest that the $\Xi_b(6227)^-$ is the $P$-wave strange partner of the $\Sigma_b(6097)^\pm$, with spin-parity $J^P = 3/2^-$ or $5/2^-$ while there are also the molecular accommodation[12]. For more discussions on the excited heavy baryons, see Refs.[13–20].

To further decode inner structure of the $\Xi_b(6227)^-$ and $\Sigma_b(6097)^\pm$, it becomes important to explore the charmed and bottom baryons in a coherent way so that these newly discovered baryons can be analysed in connection with the existing singly heavy(SH) baryons in the charm sector, e.g., the $\Sigma(2800)$ and $\Xi_c(2930)$, whose quantum numbers are not established experimentally yet [2, 21, 22]. Obviously, it will be helpful to deepen our understanding of non-perturbative QCD if some analogies were found among these SH hadron systems. For the two charmed baryons mentioned above, quark models predict their quantum number to be [17–20],

$$J^P(\Sigma_c(2800)) = 1^- \text{or } 3^-, \quad J^P(\Xi_c'(2930)) = 3^- \text{or } 5^-. \quad (1)$$

Based on the Regge trajectories, authors of Ref.[23] assign the $\Sigma_c(2800)$ and $\Xi_c'(2930)$ to be the $P$-wave states with $J^P = 3/2^-$. The purpose of this work is to explore the orbitally-excited mass spectrum of the SH baryons $qqQ$ with the help of Regge trajectory and accommodate the newly discovered bottom baryons $\Xi_b(6227)^-$, the $\Sigma_b(6097)^\pm$, as well as the charmed baryons $\Sigma(2800)$ and $\Xi_c(2930)$. Our mass analysis indicates that a linear Regge trajectory is able to describe the spin-averaged mass spectrum of the existing singly heavy baryons in their orbitally excited states. Further mass-splitting analysis of the orbitally excited SH baryons suggests that the quantum numbers of the four SH baryons considered here are $J^P = 3/2^-$ preferably. We also make the mass prediction of the bottom baryon $\Xi_b$ in its P- and D-waves, which should be tested by future experiments, especially the LHCb.

The paper is organized as follows. After the introduction, we show how the linear Regge relation can be employed to demonstrate Regge behaviors in the spin-averaged masses of orbitally excited SH baryons in Sec. II, where the trajectory parameters are discussed. In sec. III, we perform mass calculations for the orbital excitations of the SH baryons with $L = 0, 1$ and $2(\Lambda_b, \Xi_b$ cases) by including the spin-dependent interactions, and assign the $J^P$ quantum number for the $\Sigma(2800)$ and the $\Xi_c(2930)$. In Sec. IV the similar analysis is applied to the singly bottom baryons and to assign the quantum number for the newly reported baryons $\Xi_b(6227)$ and the $\Sigma_b(6097)^\pm$.

The masses of the bottom baryon states $\Xi_b$ in the P- and D-waves are also predicted. Finally, the paper ends with the discussions and summary in Sec. V.

II. SPIN-INDEPENDENT MASSES FOR SINGLY HEAVY BARYONS

The notion of Regge trajectory or Regge mass relation $L = \alpha' M^2 + a_0$ for hadrons, which connects high energy scattering and the spectrum of hadrons in general theory [24], provides us a powerful way to organize the whole spectrum of a given family of the hadrons. In the case of light hadrons, the Regge trajectories are commonly believed to be linear and parallel, and these features are also tested to be true roughly for the SH hadrons in Ref. [25] provided that the hadron mass undergoes a shift $M \rightarrow M - M_Q$, with $M_Q$ the heavy quark mass. As such, one can estimate the spin-averaged masses of $\Sigma_Q$ and $\Xi_Q$ in their orbitally-excited states with the help of the trajectory information of the partner SH baryons or mesons.

We begin with a linear Regge relation [26, 27], which is derived from the rotating string model (see Appendix A),

$$ (M - M_Q)^2 = \pi a L + \left( m_d + \frac{P_Q^2}{M_Q} \right)^2, \quad (2) $$

This relation connects the shifted mass of a SH baryon squared, $(M - M_Q)^2$, with its quantum number of orbital angular momentum $L$. Here, $a$ stands for the tension of the string connected to the heavy quark with mass $M_Q$ at one end and the light diquark with mass $m_d$ at the other, and $M$ is the mass of the heavy baryon. In Eq. (2), the intercept depends on the diquark mass $m_d$ and the non-relativistic kinematic energy $P_Q/M_Q$ of the heavy quark through $a_0 = \left( m_d + P_Q^2/M_Q \right)$, with

$$ P_Q = M_Q v_Q \approx M_Q \left( 1 - \frac{m_{bareQ}^2}{M_Q^2} \right)^{1/2}, \quad (3) $$

where $m_{bareQ} = 1.275$ GeV and 4.18 GeV are the bare masses of the heavy charmed quark $Q = c$ and bottom quark $Q = b$, respectively. Here, $v_Q = \left( 1 - \frac{m_{bareQ}^2}{M_Q^2} \right)^{1/2}$ stands for the velocity of the heavy quark, which is conserved in the heavy quark limit.

The simplest way to understand Eq. (2) is to view it as an extension of the Selem-Wilczek relation [28] for the SH hadrons,

$$ M - M_Q = \sqrt{\frac{\pi}{2}} L + 2^{1/4} \frac{\kappa Q}{L^{1/4}}, \quad (4) $$

which scales as $(M - M_Q)^2 \propto (\alpha/2) L$ when $L \rightarrow \infty$ but divergent at $L = 0$. As $L \gg 1$, Eq. (2) reduces to Eq. (4),

$$ M - M_Q = \sqrt{\pi a L} + a_0/(2 \sqrt{\pi a L}), \quad \text{while it is finite at } L = 0 \text{ and becomes} $$

$$ M(1S) = M_Q + m_d + \frac{P_Q^2}{M_Q}, \quad (5) $$

This is consistent with the prediction by the heavy quark symmetry for the ground state $(L = 0)$ [29] as $M_Q$ is very close to the bare mass of the heavy quark $Q$ when $Q$ is heavy, as indicated by Eq. (A3) in Appendix A. The heavy quark limit defined by $m_{bareQ} \rightarrow \infty$ implies $M_Q = m_{bareQ} \rightarrow \infty$ and the 3-velocity of heavy quark $v_Q \rightarrow 0$ (see Appendix A). Here, the $m_d$ plays the role of the energy of the light brown muck in a baryon in the lowest states. We note that the orbital angular momentum $L$ here corresponds to the $\lambda$ mode in the quark model [30, 31].

In the light of the rotating string model [28], one can view the heavy baryon mass $M$ as the sum of the mass $M_Q$ of heavy quark at one end of the string and the string energy $\sqrt{\pi a L} + a_0$, with the light diquark tied to the other. We note that the full quantum treatment [32, 33] of the QCD string provides merely an additional constant $a_0$ added to $L$ as expected by the Regge trajectory of hadrons.

As will be seen in what follows, the mass of the diquark $(qq)_d$ in Eq. (2) varies when the strangeness and its spin involve. In a SH baryon with zero strangeness, the diquark can be either of scalar (spin=0) or of vector (spin=1),

$$ (qq)_d = \begin{cases} \{ud\}, & I = 0 \text{ spin, in } \Lambda_Q, \\ \{uu, ud, dd\}, & I = 1 \text{ spin, in } \Xi_Q. \end{cases} $$

while in those with strangeness $=-1$, it can be either of scalar (spin=0) or axial vector (spin=1)

$$ (qs)_d = \begin{cases} \{us, ds\}, & I = 1/2, \text{ spin } 0, \text{ in } \Xi_Q, \\ \{us, ds\}, & I = 1/2, \text{ spin } 1, \text{ in } \Xi_Q. \end{cases} $$

To confront Eq. (2) with the baryon mass data, we list in Table I the observed masses of the heavy baryons $\Lambda_Q$ and the strange heavy baryons $\Xi_Q$, and the ground state $(Q = c, b)$, and in Table II that of the heavy baryons $\Sigma_Q$ and the strange heavy baryons $\Xi'_Q$ of the heavy quark $Q = c, b$. In Tables IX, the observed spin-averaged masses for the family of orbitally excited SH baryons are collected with the weight $2J + 1$ (with $J$ the angular momentum of the baryon), and are fitted by the relation (2), in which the estimated mass can be rewritten as, upon using Eq. (3),

$$ M_L = M_Q + \sqrt{\pi a L + \left[ m_d + M_Q - \frac{P_Q^2}{M_Q} \right]^2}. \quad (6) $$

In Table III, IV and V, the trajectory parameters reproducing the observed masses in Table I and Table II are listed for the charmed baryons $\Lambda_c$ and $\Sigma_c$, and for the baryons $\Sigma_c$ and charm-strange baryons $\Xi'_c$, respectively, including the ensuing P-wave spin-averaged masses predicted by Eq. (6). The resulted parameters are compared with the quark model predictions [17] in the three tables. In Table IX, the observed spin-averaged masses are collected for all relevant baryons except for the baryons $\Sigma_Q$ and $\Xi'_Q$, $(Q = c, b)$, and the spin-averaged masses predicted by Eq. (2) via the parameters given in Table

| \(\Lambda_c, 1P\) | 2616 | 2615.5 | \(\Xi_c, 1P\) | 2808 | 2803.9 |
| \(\Lambda_c, 1D\) | 2871 | 2871.1 | \(\Xi_c, 1D\) | 3069 | 3071.3 |
| \(\Lambda_b, 1S\) | 5619 | 5619 | \(\Xi_c, 1S\) | 5792 | 5798.1 |
| \(\Lambda_b, 1P\) | 5917 | 5616.3 | \(\Xi_c, 1P\) | -- | 6125.1 |
| \(\Lambda_b, 1D\) | 6148 | 6149.3 | \(\Xi_c, 1D\) | -- | 6380.9 |
| \(\Sigma_c, 1S\) | 2497.0 | 2496.1 | \(\Xi_c, 1S\) | 2624 | 2623.1 |
| \(\Sigma_c, 1P\) | -- | 2774.1 | \(\Xi_c, 1P\) | -- | 2923.0 |
| \(\Sigma_c, 1S\) | 5825 | 5825.0 | \(\Xi_c, 1S\) | 5949 | 5949.0 |
| \(\Sigma_c, 1P\) | -- | 6084.4 | \(\Xi_c, 1P\) | -- | 6248.2 |

III,IV and V are also shown for comparisons. Here, we assumed the orbital trajectories of the \(\Sigma_c(\Xi_c)\) and the \(\Lambda_c(\Xi_c')\) to be parallel, leading to the same string tensions between them.

We also apply Eq.(2), with \(m_d\) everywhere replaced by the effective masses of light(strange or \(u/d\)) antiquarks, to the heavy-light \((Q\bar{q})\) mesons whose observed masses are listed in Tables VI and VII, and list in Table VIII the determined trajectory parameters, namely, the effective masses \(m_o\), of light \(u/d\) quark and the strange quark, and the string tensions \(a\) for the \(D/D_s\) mesons and the \(B/B_s\) mesons. The resulting parameters are compared to that in the quark model \[34\] for the heavy-light mesons.

From Table III one sees that the predicted spin-averaged masses 2618 MeV and 2804 MeV of the 1P-wave \(\Lambda_c\) and \(\Xi_c\) are very close to the corresponding values 2616 MeV and 2808 MeV in Tables I, respectively. Furthermore, the following remarks are in order.

(1) The mass differences between the S-wave SH baryons \(\Sigma_c\) and \(\Lambda_c\) are equal to that between the diquarks (of scalar or vector type) contained in them,

\[
m_d(\Sigma_c) - m_d(\Lambda_c) = 210\text{MeV} = \bar{M}(\Sigma_c) - M(\Lambda_c),
\]

and

\[
m_d(\Xi_c') - m_d(\Xi_c) = 154\text{MeV} = \bar{M}(\Xi_c') - M(\Xi_c).
\]

This imposes a constraint on the masses of the vector diquark which are crucial for predicting, through Eq.(2), the spin-averaged masses of the P-wave excitations of the baryons \(\Sigma_c\) and \(\Sigma_c'\). The latter are less established experimentally, as shown in Table II.

(2) The mass values of the heavy quark and light diquarks in our approach are in consistent with that in the relativistic quark model. The string tension \(a\) in our approach is flavor-dependent weakly, with a rising about 0.04GeV\(^2\) (0.06GeV\(^2\)) for the charmed(bottom) baryons when diquark flavor in them changes from \(nn\) to \(ns(n = u, d)\).

(3) Once determined, the diquark masses of both types can be applied to explore the Regge behaviors in the bottom partner of the charmed baryons, for which the less data are available experimentally.

### III. INCLUDING MASS SPLITTING FOR ORBITAL EXCITATIONS

To estimate the mass splitting in orbitally excited charmed and bottom baryons \(Q\bar{q}q(Q = c, b, q = u/d, s, qq \neq ss)\), one needs to consider the spin-dependent interaction which was ignored in Eq.(2). In the light of QCD string, the orbital motion of QCD string[34] contributes dominantly to total angular moment \(L\) of the system, which makes the quark-diquark potential nontrivial(\(L\)-dependent) effectively. For simplicity, we follow Ref. [35] to compute the spin-dependent mass for \(L = 0, 1\) and \(2(\Lambda_Q, \Xi_Q\) case only) via the scaling relation between heavy baryons \(Q\bar{q}q\) and their meson partners \(Q\bar{q}\)(note that the color-structure similarity between baryon and meson is implicitly assumed in the quark-diquark picture). The spin-dependent interaction we consider is[17, 35]

\[
H^{SD} = a_1L \cdot S_d + a_2L \cdot S_Q + bS_{12} + cS_d \cdot S_Q,
\]

\[
S_{12} = 3S_d \cdot \hat{r}S_Q \cdot \hat{r} - S_d \cdot S_Q,
\]

where the first two terms are spin-orbit energies, the third is the tensor energy, and the last describes the hyperfine splitting between the heavy quark with spin \(S_Q\) and diquark with spin \(S_d\). Here, \(L\) is the orbital angular momentum of the baryons. The first term(\(a_1\)-term) is obviously larger than the others (especially for the bottom systems) as these terms all involve the magnetic moment \(S_Q/M_Q\) of heavy quark when viewing Eq.(9) as a spin-relevant relativistic correction.

(A) The S-wave baryons(\(L = 0\)). In this case, only the last term survives in Eq.(9), \(H^{SD} = cS_d \cdot S_Q\). Note that \((S_d \cdot S_Q) = [S(S + 1) - S_Q(S_Q + 1) - S_d(S_d + 1)])/2\) becomes 0 when the conserved total quark spin \(S\) (= \(J\) here)= 1/2 and \(S_d = 0\), and...
has the value $-1$ and $1/2$, when $S_L = 1$ and $S = 1/2, 3/2$, respectively. Thus, the mass for the $1S$-wave states is

$$M(1S)_{S_J=0} = \tilde{M}_{L=0}, (\Lambda_Q, \Xi_Q).$$

$$M(1S)_{S_J=1} = \tilde{M}_{L=0} + c \begin{pmatrix} -1 & 0 \\ 0 & 1/2 \end{pmatrix}, (\Sigma_Q, \Xi_Q').$$

For the baryon $\Lambda_Q$ and $\Xi_Q$ containing an light scalar diquark (spin $S_d = 0$), the total spin $S = 1/2 = J$. This corresponds to a single baryon ground state $I^J S_1/2$. The ground state masses of the baryons $\Lambda_Q$ and $\Xi_Q$ are given simply by their spin-independent masses in Eq.(2). To estimate $c$ for the baryon $\Sigma_Q$ and $\Xi_Q'$ which contain the light vector diquark (spin $S_d = 1$), we employ the following scaling relation to the partner in heavy mesons,

$$c(Q\bar{q}) = \frac{m_q}{m_d(Q\bar{q})}c(Q\bar{q}),$$

which stems from the inverse-mass scaling inherent in the contact interaction ($\sim$ the diquark magnetic moment $S_d/m_d$).

Extracing $c(Q\bar{q})$ from the splitting between the $Q\bar{q}$ meson mass $M(1^3S_1, 1^-)$ and $M(1^1S_0, 0^-)$ in the case of the $D$ mesons (see Table VI):

$$c(Q\bar{q}) = M(1^3S_1, 1^-) - M(1^1S_0, 0^-) = 140.6 \text{ MeV},$$

one estimates, by Eq.(12),

$$c = 140.6 \times \begin{pmatrix} 230/745 \\ 230/872 \end{pmatrix} = \begin{pmatrix} 43.4(\Sigma_Q) \\ 37.1(\Xi_Q') \end{pmatrix}.$$ 

Having $c$ given by Eqs.(14), Eqs.(10-11) give masses for the $S$-wave charmed baryons, as listed in Table I and Table II, respectively.

(B) The $P$-wave baryons ($L = 1$). For the baryon $\Lambda_Q$ and $\Xi_Q$ containing spin $0$ diquarks, the $P$-wave states correspond to two baryon states of $J^P = 1/2^-$ and $3/2^-$. This can be written as

$$0_d \otimes (1/2)_Q \otimes L = \frac{1}{2} \oplus 3/2$$

in the notation of symmetry group, where the notations $\otimes$ and $\oplus$ stand for the coupling (adding of the angular momentum in the standard terminology) and the juxtaposition of the angular momentum shown. In the charm sectors, for instance, there are four $P$-wave candidates $\Lambda_c(2595)^+$ and $\Lambda_b(2625)^+$, $\Xi_c(2790)^+$ and $\Xi_b(2815)^+$[2] (see Table I). The masses and possible quantum numbers for the observed low-lying baryons $\Lambda_c$ and $\Xi_c$ are summarized in Table I.

For the baryon $\Sigma_Q$ and $\Xi_Q'$ containing spin $1$ diquarks, the five $P$-wave states $J = 1/2^-, 3/2^-, 1/2^+, 3/2^+$ and $5/2$ with negative parity are allowed:

$$\begin{pmatrix} 1/2 \otimes (1/2)_Q \otimes L = \frac{1}{2} \oplus 3/2 \oplus 5/2 \end{pmatrix}.$$ 

The current candidates of these $P$-wave charmed baryons are the $\Sigma_c(2800)^{0,+,*}$ in the nonstrange sector and the $\Sigma_c(2930)^{0,+}$ in the strange sector, whose spin and parity have not been established yet[2]. The quark model assignments are given by Eq.(1). The masses and possible quantum numbers for the observed low-lying baryons $\Sigma_c$ and $\Xi_c'$ are summarized in Table II, with the question marks indicating that their $J^P$ assignments are unknown experimentally.

A normal scheme (the $L$-$S$ coupling) of computing mass splitting by Eq. (9) is to couple the diquark spin $S_d$ to the heavy quark spin $S_Q$ first and then to the orbital angular momentum $L$ of the system, as shown in (15) for $S_d = 1$ case. In the $L$-$S$ basis the two $J = 1/2$ states and the two $J = 3/2$ states are usually mixed unless $a_1 = a_2$. They are eigenstates of $2 \times 2$ matrices $M_j$ given in the basis $|^{2}P_{J}\bar{q}, P_{J}\bar{q}, \rangle$.

Using the $1P$-wave wavefunctions of the heavy quark-diquark systems in the basis of $|L, S_Q, S_{dL}, \rangle$, these matrices can be evaluated and given by (Appendix B)

$$\langle L \cdot S_d \rangle_{J=\frac{3}{2}} = \begin{pmatrix} \frac{1}{2} - \frac{\sqrt{3}}{3} \\ -\frac{\sqrt{3}}{3} - \frac{\sqrt{3}}{3} \end{pmatrix}$$

and $\langle L \cdot S_d \rangle_{J=\frac{5}{2}} = 1$, $\langle L \cdot S_d \rangle_{J=\frac{5}{2}} = 1/2$. The two matrices above have the eigenvalues $-1, -2$ for $J = 1/2$ and the eigenvalues $\pm 1$ for $J = 3/2$.

One can also choose an alternative scheme (the $j$-$j$ coupling) in which the diquark spin $S_d$ couples to $L$ first and then to the conserved spin $S_Q$ of the heavy quark. In the $L$-wave case ($L = 1$), for instance, this scheme reads,

$$[0_d \otimes 1_L] \otimes \langle \frac{1}{2} \rangle_{Q} = 1_J \otimes \langle \frac{1}{2} \rangle_{Q} = \frac{1}{2} \oplus \frac{3}{2},$$

for the baryons $\Lambda_Q$ and $\Xi_Q$, and takes form

$$[1_d \otimes 1_L] \otimes \langle \frac{1}{2} \rangle_{Q} = 0_J \oplus 1_J \otimes \langle \frac{1}{2} \rangle_{Q} = \frac{1}{2} \oplus \frac{3}{2} \oplus \frac{3}{2} \oplus \frac{5}{2},$$

for the baryons $\Sigma_Q$ and $\Xi_Q'$. Since the interactions other than the $L \cdot S_d$ term in (9) are suppressed by $1/M_Q$, one can compute the mass splitting in a basis in which $L \cdot S_d$ is diagonal, with the other interactions treated perturbatively.

Notice that $\langle L \cdot S_d \rangle = \langle j(j + 1) - L(L + 1) - S_d(S_d + 1) \rangle / 2$ takes values $-2, -1$ and $1$ when $j = 0, 1, 2$, respectively, one can use the eigenfunction of the $L \cdot S_d$ to evaluate the mass splitting operators in Eq.(9) in the $j$-$j$ coupling (Appendix B).

The results are listed in Table X, from which the mass splitting $M(J, j) = \langle J, j | H^{PD} | J, j \rangle$ can be evaluated in the $|J, j\rangle$ basis. Written in terms of three parameters $(a_1, a_2, c, b)$, the results are (see Ref. [36]) for details, which corrected an error in Ref. [35]

$$M^{PD}(1/2, 0) = -2a_1,$$

(16)
One additional constraint stems from the vanishing of these splitting as a sum: $\mathbf{S}_1^D = 0$, which is
\begin{equation}
10M^D(1/2, 0) - 15M^D(1/2, 1) + 8M^D(3/2, 2) = 3M^D(5/2, 2).
\end{equation}

Following Ref. [35], one can calculate the parameters \(a_1, a_2, b\) in Eq. (9) for the heavy baryon \(Q\bar{q}(u/d, s)\) by assuming the following mass scaling, which relates these parameters to that for the heavy mesons \(Q\bar{q}\) with effective antiquark mass \(m_q\), or relates the parameters among the heavy flavor partners \((bqq\text{ and }cqq)\).

\begin{equation}
a_1(Q\bar{q}) = a_1(Q\bar{q}) \left( \frac{m_q}{m_d(q\bar{q})} \right),
\end{equation}

\begin{equation}
a_1(b) = a_1(c), a_2(b) = a_2(c) \left( \frac{M_b}{M_c} \right), b(b) = b(c) \left( \frac{M_b}{M_c} \right),
\end{equation}

where \(b, c\) in parenthesis stand for the bottom and charm sectors. In evaluating the coupling \(a_2\) for the charred baryons, a simple way is to estimate it via that for the charm mesons by resembling the charred baryon \(cqq\) to the charmed meson \(c\bar{q}\) systems. Considering the finite mass effects of the charm quark which differ between the charmed baryons and the charmed mesons, we use a recoil factor \((1 + m_d/M_Q)\) to partially remedy the uncertainty that may happen in this resembling.

\begin{equation}
a_2(cqq) = \frac{a_2(c\bar{q})}{1 + m_d/M_c}.
\end{equation}

In the following, we describe very briefly how to evaluate the parameters \(a_1, a_2, b\) for the charmed-strange mesons for which the spin-dependent Hamiltonian is given by Eq. (9) in which \(S_0\) is replaced by \(S_5\). Firstly, one can derive a counterpart of Eqs. (16-20) for \(Q\bar{q}\) system via a calculation similar to the P-wave heavy baryons and obtain the mass for the P-wave spin multiplets of the heavy mesons \((Q\bar{q})\) in the \([J, J]\) states \((J = L_1 + S_3, L = 1)\). The results are (Appendix C: Eq. (C8-C11)):

\begin{equation}
M(0, 1/2) = \tilde{M} - a_1 - a_2 - b - \frac{c}{10}.
\end{equation}

\begin{equation}
M(1, 1/2) = \tilde{M} - a_1 + \frac{1}{3} a_2 + \frac{1}{3} b - \frac{c}{12},
\end{equation}

\begin{equation}
M(1, 3/2) = \tilde{M} + \frac{1}{2} a_1 - \frac{5}{6} a_2 + \frac{1}{6} b - \frac{5 c}{12},
\end{equation}

\begin{equation}
M(2, 3/2) = \tilde{M} + \frac{1}{2} a_1 + \frac{1}{2} a_2 - \frac{1}{10} b + \frac{c}{4}.
\end{equation}

Secondly, confronting the observed masses of the \(D_b\) mesons in the P-wave (see Table VI), one can find the parameters \([a_1, a_2, b]\) for the heavy mesons \(D_b\) reproducing their observed mass spectrum via Eqs. (16-20). Ignoring \(c\) vanishes almost in the P-wave, one can find lastly [35] (see Appendix C: Eq. (C12)):

\begin{equation}
\left\{ \tilde{M}(\text{MeV}), a_1(\text{MeV}), a_2(\text{MeV}), b(\text{MeV}) \right\} = \begin{pmatrix} 2513.4, & 89.4, & 40.7, & 65.6. \end{pmatrix}
\end{equation}

Given \(a_1\) in Eq. (29) for the \(D_b\) mesons in P-wave, the diquark masses in Table III and IV and the strange quark mass in Table VIII, Eq. (22) gives

\begin{equation}
\Sigma_c, 1P : a_1(c\bar{s}) \left( \frac{m_{c\bar{s}}(q\bar{q})}{m_{c\bar{s}}} \right) = 89.4 \text{MeV} \left( \frac{328}{3} \right) = 39.4 \text{MeV},
\end{equation}

\begin{equation}
\Xi_c, 1P : a_1(c\bar{s}) \left( \frac{m_{c\bar{s}}(q\bar{q})}{m_{c\bar{s}}} \right) = 89.4 \text{MeV} \left( \frac{328}{3} \right) = 33.6 \text{MeV},
\end{equation}

For the charmed baryons \(\Sigma_c\) and \(\Xi_c\), Eq. (24) with \(m_d\) given in Table IV gives

\begin{equation}
a_2(\Sigma_c, 1P) = \frac{a_2(D_b)}{1 + m_d/M_c} = \frac{40.7}{1 + m_d/M_c} = 26.8 \text{MeV},
\end{equation}

\begin{equation}
a_2(\Xi_c, 1P) = \frac{a_2(D_b)}{1 + m_d/M_c} = \frac{40.7}{1 + m_d/M_c} = 25.3 \text{MeV},
\end{equation}

while for the charmed baryons \(\Lambda_c\) and \(\Xi_c\), the parameter \(a_2\) become slightly larger when using Eq. (29) and the diquark masses given in Table III. We take \(a_2(\Lambda_c, 1P) = a_2(\Sigma_c, 1P)\) and \(a_2(\Xi_c, 1P) = a_2(\Xi_c, 1P)\) for simplicity as this varying in \(a_2\) is small at the mass scale of the P-wave charmed baryons, as shown explicitly in Figs. 1-2. Eq. (31) are in consistent with the values of \(a_2\) that match the observed P-wave masses of the baryons \(\Lambda_c\) and \(\Xi_c\):

\begin{equation}
a_2(\Lambda_c) = 24 \text{MeV}, a_2(\Xi_c) = 16 \text{MeV}.
\end{equation}

These two values follows from the mass differences (see Table I) between the \(J = 3/2^-\) and \(J = 1/2^-\) states of the baryon \(\Lambda_c\) and the \(\Xi_c\), respectively, which depend only on the second term in Eq. (9) when \(S_d = 0\), that is, \(M(J = 3/2^-) - M(J = 1/2^-) = 3a_2/2\).

As \(S_d = 0\) for the \(\Lambda_c\) and the \(\Xi_c\), the mass splitting operator for them simplifies, \(H_3^D = a_2L\cdot S_0\), which gives the mass in the \([J = 1/2, J = 1]\) and \([J = 3/2, J = 1]\):

\begin{equation}
M(\Lambda_c/\Xi_c, 1P) = \tilde{M}_{c = 1} + a_2(\Lambda_c/\Xi_c) \begin{pmatrix} -1 & 0 \\ 0 & 1/2 \end{pmatrix},
\end{equation}

Table X: The matrix elements of the mass splitting operators in the P-wave baryon states in the \(J-j\) coupling

| \((J, j)\) | \((L \cdot S_0)\) | \((S_12)\) | \((S_4 \cdot S_0)\) |
|---|---|---|---|
| \((1/2, 0)\) | 0 | 0 | 0 |
| \((1/2, 1)\) | -3 | -1 | -3 |
| \((3/2, 1)\) | 3 | 1 | 3 |
| \((3/2, 2)\) | -3 | 1/10 | -3 |
| \((5/2, 2)\) | 3 | -3/10 | 3 |
where the expectation values of \( I \cdot S_Q \) is given by \( [J(J + 1) - L(L + 1) - S_Q(S_Q + 1)]/2 \), taking values \(-1\) for \( J = 1/2 \) and \(+1/2\) for \( J = 3/2 \). The computed masses via Eqs. (33) and (31) for the P-wave \( \Lambda_c/\Xi_c \) are collected in Table I.

Putting all together and ignoring the spin-spin \( c \)-term (quite small) in the P-wave, it follows from Eqs.(16-20) that the mass splitting in the P-wave are

\[
\begin{align*}
M(1/2, 0) &= 2694.74, \\
M(1/2, 1) &= 2722.64 - b, \\
M(3/2, 1) &= 2740.37 + \frac{1}{2} b, \\
M(3/2, 2) &= 2795.63 + \frac{3}{10} b, \\
M(5/2, 2) &= 2825.63 - \frac{1}{5} b.
\end{align*}
\]

for the baryon \( \Sigma_c \), and

\[
\begin{align*}
M(1/2, 0) &= 2855.76, \\
M(1/2, 1) &= 2881.38 - b, \\
M(3/2, 1) &= 2893.38 + \frac{1}{2} b, \\
M(3/2, 2) &= 2938.62 + \frac{3}{10} b, \\
M(5/2, 2) &= 2964.62 - \frac{1}{5} b.
\end{align*}
\]

for the baryon \( \Xi'_c \), which are plotted against \( b \) in FIG.1 and FIG.2, respectively. Each pair of the adjacent lines corresponds to the choice \( a_2 \) given in Eq. (31) (dotted lines) and Eq. (32) (solid lines), respectively. As shown in FIG. 1, for moderate values of \( b \), there is a clear separation between the three lowest masses \( M(1/2, j = 0), M(1/2, j = 1), M(3/2, j = 1) \), and the two highest masses \( M(3/2, j = 2) \) and \( M(5/2, j = 2) \).

Without loss of the generality, we assume that \( b \) is of same order with \( a_2 \) (note that \( a_2 = b \) in the quark model[37] of the heavy-light mesons in the heavy quark limit). The mass function \( M(3/2, j = 2) \) in FIG.1 approaches the observed mass of the \( \Sigma_c(2800)^{0+,++} \) at \( b \) around 20MeV, while the mass function \( M(3/2, j = 2) \) meets the observed averaged mass 2936MeV of the \( \Xi_c(2930) \) and \( \Xi_c(2942) \). Also, the mass function \( M(3/2, j = 1) \) slowly tends to approach the mass of the \( \Xi_c(2930) \) at larger \( b \) in FIG. 2. In both cases, the P-wave states with the spin-parity \( J^P = 3/2^- \) is favored. The states with \( J^P = 3/2^- \) and \( 5/2^- \) can be the states most likely being relatively narrow and thereby easier to observe when they decay via the higher partial wave(D-wave), as discussed in section IV.

(C) The D-wave baryons \( L = 2 \). We consider only the baryon \( \Lambda_Q \) and \( \Xi_Q \) containing spin = 0 diquarks due to the limited experimental information for the charged mesons(\( \eta \)) in D-wave on which our calculation depends. Two possible D-wave states are the baryon states of \( J^P = 3/2^+ \) and \( 5/2^+ \), which can be written as

\[
\left[ 0_s \otimes \frac{1}{2}, \frac{1}{2} \right] \otimes 2_L = \frac{3}{2} \oplus \frac{5}{2}.
\]

In the charm sectors, for instance, there are four D-wave candidates, the \( \Lambda_c(2860)^+ \), the \( \Lambda_c(2880)^+ \), the \( \Lambda_c(3055)^+ \) and the \( \Xi_c(3080)^+ \) [2], as shown in Table I where the other masses and their quantum numbers are also summarized.

Given \( S_Q = 0 \) for the baryon \( \Lambda_Q \) and \( \Xi_Q \) the mass splitting operator is \( H^{D} = a_2 I \cdot S_Q \), which gives the mass in the basis \( |3/2, j = 2 \rangle \) and \( |5/2, j = 2 \rangle \):

\[
M(\Lambda_Q/\Xi_Q, 1D) = M_{L=2} + a_2 \begin{pmatrix} -3/2 & 0 \\
0 & 1 \end{pmatrix}.
\]

Employing the parameterized mass in Eqs.(C19-C22) stemming from Eq.(9) in the \( j \cdot j \) coupling and confronting it with the observed masses of the \( D \) mesons in D-wave in Table XII(see Appendix C), one finds \( a_2 = 12.6 \text{MeV} \)(see Eq.(C23) for details). It follows from Eq.(24), with \( m_d \) in Table III,

\[
a_2(cqq) = \frac{12.6 \text{MeV}}{1 + m_d/1.44} = \left\{ \begin{array}{cl}
9.2 \text{MeV}(\Lambda_c) \\
8.4 \text{MeV}(\Xi_c) \end{array} \right.
\]

by which all computed masses of the D-wave charmed baryons in Table I follow.

![FIG. 1: The masses of the P-wave \( \Sigma_c \) against the parameter \( b \).](image)

**IV. MASS SPLITTING FOR THE SINGLY BOTTOM BARYONS**

One can apply the calculational method similar to section III to the singly bottom baryons. Differing from the charmed baryons, one can improve the computational accuracy for the bottom baryons via the scaling relation to the charmed baryons(note that there are few higher partial waves for the \( B_s \) mesons in Table VII). The masses and the quantum numbers for the observed low-lying baryons \( \Lambda_b \) and \( \Xi_b \) are summarized in Table I, whereas in Table II, we list mainly the observed lowest baryons \( \Sigma_b \) and \( \Xi_b \) and the newly-observed
excited baryons $\Sigma_b'(6097)$ and $\Xi'_b(6227)$, including the resonances $\Lambda_b(6146)$ and $\Lambda_b(6152)$ discovered very recently by the LHCb Collaboration.

(A) The S-wave baryons ($L = 0$). Only the last (contact) term in Eq. (9) survives for the bottom baryons ($\Sigma_b', \Xi_b'$) while Eq. (9) vanishes for the bottom baryons ($\Lambda_b, \Xi_b$) for which both $L$ and $S_L$ vanish. Considering the contact term is suppressed by the magnetic moment $M_Q/M_\Omega$, the computation of the parameter $c$ for the bottom baryons ($\Sigma_b', \Xi_b'$) can be obtained by the following heavy-quark mass scaling

$$c = c(\Sigma_b) \left( \frac{M_c}{M_b} \right) = \begin{cases} 12.8(\Sigma_b) \\ 10.9(\Xi_b') \end{cases}.$$

Given $c$ in Eq.(46), Eqs.(10-11) lead to the masses for the S-wave bottom baryons, as listed in Table V and II, respectively.

(B) The P-wave baryons ($L = 1$). A classification that is similar to the charmed baryons in section III(B) can be given to the baryon state (namely, $Q \rightarrow b$). Using the scaling (23) for the bottom hadrons where $Q = b$, one can calculate $a_1$,

$$\Sigma_b: \quad a_1(1P) = a_1(\Sigma_b(1P)) = 39.4\text{MeV},$$

$$\Xi_b': \quad a_1(1P) = a_1(\Xi_b'(1P)) = 33.6\text{MeV}.$$

For the parameter $a_2$ for the singly bottom baryons, the scaling (23) gives, using $a_2$ for the SH mesons given in Eq. (32),

$$a_2(\Sigma_b) = a_2(\Sigma_c) \left( \frac{M_c}{M_b} \right) = 24 \left( \frac{4.4}{4.8} \right) = 7.7\text{MeV},$$

$$a_2(\Xi_b') = a_2(\Xi_c') \left( \frac{M_c}{M_b} \right) = 16 \left( \frac{4.4}{4.8} \right) = 5.1\text{MeV}.$$

Note that they are smaller than $a_1$ roughly by factor of 1/5. For the $\Lambda_b/\Xi_b$, Eq.(25) leads to, using $a_2$ in the charm sector given in Eq. (31),

$$a_2(\Lambda_b) = a_2(\Lambda_c) \left( \frac{M_c}{M_b} \right) = 8.61\text{MeV},$$

$$a_2(\Xi_b) = a_2(\Xi_c) \left( \frac{M_c}{M_b} \right) = 8.13\text{MeV}.$$

Including the spin-dependent mass splitting, the relation similar to Eq.(33) yields

$$M(\Lambda_b/\Xi_b, 1P) = M(0) + a_2(\Lambda_b) \left[ \begin{array}{cc} -1 & 0 \\ 0 & 1/2 \end{array} \right],$$

which gives, combining with the spin-averaged masses in Table V and Eq. (48), the mass predictions for the P-wave baryons $\Lambda_b$ and $\Xi_b$. The results as collected in Table I.

Knowing the coupling strengths $a_1$ and adding the spin-independent masses in Table V to the mass splitting (16)-(20), one can find the masses of the P-wave spin multiplets,

$$M(1/2, 0) = 6009,$$

$$M(1/2, 1) = 6046 - b,$$

$$M(3/2, 1) = 6050 + \frac{1}{2}b,$$

$$M(3/2, 2) = 6124 + \frac{3}{10}b,$$

$$M(5/2, 2) = 6130 - \frac{1}{5}b.$$

for the bottom baryon $\Sigma_b$, and

$$M(1/2, 0) = 6181,$$

$$M(1/2, 1) = 6211 - b,$$

$$M(3/2, 1) = 6216 + \frac{1}{2}b,$$

$$M(3/2, 2) = 6277 + \frac{3}{10}b,$$

$$M(5/2, 2) = 6285 - \frac{1}{5}b.$$

for the baryon $\Xi_b'$, which are plotted against $b$ in FIG. 3 and FIG. 4, respectively. Note that two adjacent lines in the plots are very close and not distinguishable for the two choices in Eq. (47) and Eq. (48) and hence only the later case is shown in FIG. 3 and FIG. 4.

In FIG. 3, the observed mass of the $\Sigma_b(6097)^-$ pass through the gap between two mass functions $M(3/2, j = 1, 2)$ while in FIG. 4 the line of the mass function $M(3/2, j = 1)$ approaches the mass of the $\Xi_b'(6227)^-$ at about $b = 20$ assuming $b$ is positive. In former case, agreement with data can be achieved most likely when the states $|3/2, j = 1, 2\rangle$ mixes. In both cases, the spin-parity $J' = 3/2^-$ is favored for the $\Sigma_b(6097)^-$ and $\Xi_b'(6227)^-$. The states with $J' = 3/2^+$ are easier to observe since they decay strongly only via D-wave and are relatively narrow.

(C) The D-wave baryons $\Lambda_b/\Xi_b$. We compute, as an example, the masses of the $\Lambda_b(1D)$. Using the trajectory parameters in Table V, and $M_b\gamma_5^2 = 4.48(1 - 4.18^2/4.48^2) = 0.5799\text{GeV}$, Eqs. (2-3) yield a spin-averaged mass for the $D$-wave,

$$M(1D) = 4.48 + \sqrt{2\pi \cdot 0.246 + 0.534 + 0.5799^2} = 6.1492\text{GeV},$$

which agrees remarkably well with the observed spin-averaged mass 6149.97MeV of the new resonances.
$\Lambda_b(3/2^+, 5/2^+)$ reported very recently by LHCB\cite{38}:

$$M[\Lambda_b(6146)^0] = 6146.17 \pm 0.33 \pm 0.22 \pm 0.16 \text{MeV},$$

$$M[\Lambda_b(6152)^0] = 6152.51 \pm 0.26 \pm 0.22 \pm 0.16 \text{MeV}.$$  

Given the difference 5/2 in $L$ - $S_0$ between the 5/2$^+$ and 3/2$^+$ states, one can extract $a_2$ for the $\Lambda_b(1D)$ to have $a_2[\Lambda_b(1D)] = 2^{1/2} [\Lambda_b(5/2^+) - \Lambda_b(3/2^+)] = 10.21 \text{MeV}$. The scaling relation (23) gives then

$$a_2[\Lambda_b(1D)] = a_2[\Lambda_b(1D)] \left( \frac{1.44}{4.48} \right) = 3.28 \text{MeV},$$

which predicts (in MeV), by Eq. (44),

$$M[\Lambda_b(1D)] = 6149.3 + 3.28 \begin{bmatrix} -3/2 & 0 \\ 0 & 1 \end{bmatrix}$$

$$= \left[ \begin{array}{cc} 6144.4 & 0 \\ 0 & 6152.6 \end{array} \right].$$

corresponding to $J = 3/2^+, 5/2^+$, respectively. This is in good agreement with the observations.

Due to the lacking of the $B/B_s$ meson data for D-wave unfortunately, we are not able to test the scaling relation (24) directly with the SH mesons. An alternative is to verify it via scaling from the $D(1D)$ mesons to the $\Lambda_b(1D)$ and then to the $\Lambda_b(1D)$. Combined with Eq.(22) and (C23) in Appendix C, Eq. (24) yields

$$a_2[\Lambda_b] = a_2[\Lambda_b(1D)] \left( \frac{M_{c}}{M_{b}} \right) = \frac{a_2[D(1D)] \left( \frac{M_{c}}{M_{b}} \right)}{1 + m_{d}/M_{c}}$$

$$= \frac{12.6 \text{MeV} \times 1.44}{1 + 0.535/1.44} = 2.95 \text{MeV}, \quad (60)$$

which gives

$$M[\Lambda_b(1D)] = 6149.27 \pm \{-3/2, 1\} \times 2.95$$

$$= (6144.8, 6152.2) \text{MeV}.$$  

This agrees with the LHCB observations equally well. The same procedure as in Eq. (60) applies for computing the D-wave masses of the $\Xi_b$, with the results collected in Table I.

Finally, we explain why the some of the four observed SH baryons discussed in this work can not be the lower $J^P = 1/2^-$ multiplet in the P-wave SH baryons so that they can be seen easily experimentally comparing with the $J^P = 3/2^-$ multiplets. In the following, we choose $\Xi'_b(6227)^-$ as an example to address this question briefly in the light of strong decay behavior which was not the main topics of this work. For more discussions on decays of the $\Sigma_b(6097)/\Xi'_b(6227)^-$, see the literatures [8–10, 16].

First of all, we note that experiments by LHCB using $pp$ collision data found the $\Xi'_b(6227)^-$ to be relatively narrow\cite{39, 41}

$$\Gamma[\Xi'_b(6227)^-] = 18.1 \pm 5.4 \pm 1.8 \text{MeV},$$

In principle the 1/2$^-$ assignment for the $\Xi'_b(6227)^-$ is allowed since in the P-wave the diquark angular momentum can be $j = 1 \oplus 1 = \{0, 1, 2\}$ and couple with $S_Q = 1/2$ to give $J = 1/2$. If this is the case, the decay to the 1/2$^+$ ground-state $\Xi_b\pi^{-}$ (or $\Lambda_bK^{-}$) is very likely to happen via the S-wave by absorbing the $L = 1$ orbital motion into the diquark system to flip the spin of one quark in diquark $bs\bar{q}q^{\dagger}(1P) \rightarrow bs\bar{q}q^{\dagger}(15/12) + q^{\dagger}\bar{q}^{\dagger}(S$-wave). This yields normally a large decay width, contradictory with the relatively narrow width of the $\Xi'_b(6227)$ shown above. For the $J^P = 3/2^-$ SH baryons in P-wave, this kind of absorbing is prohibited by the angular momentum conservation, and the P-wave decay is also banned by the parity. So the $\Xi'_b(6227)$ can decay strongly only via D-wave which agrees with its relatively narrow width due to the higher $L$ suppression. So, unlike the 1/2$^-$ state, a 3/2$^-$ baryon $\Xi_b$ in P-wave is easier to be seen in experiments due to its relatively narrow width. In addition, though the 5/2$^-$ assignment for the $\Sigma_b(6097)$ seems to be marginal, it can not be excluded fully in the light of our mass analysis.

![FIG. 3: The masses of the P-wave $\Xi_b$ against the parameter $b$.](image1)

![FIG. 4: The masses of the P-wave $\Xi'_b$ against the parameter $b$.](image2)
In this work we use Regge approach in the heavy quark-diquark picture to re-examine the orbitally excited spectrum of the charmed and bottom baryons. Our analysis via a simple linear Regge relation (2) with the baryon mass shifted by the heavy quark mass \(M \rightarrow M - M_Q\) indicates that the relation is able to describe the spin-averaged mass spectrum of the orbitally-excited charmed and bottom baryons(\(\Lambda_Q, \Xi_Q, \Sigma_Q\) and \(\Xi'_Q, Q = c, b\)). The further computations on spin-dependent mass splitting suggest that the baryons \(\Xi_Q(6227)^-\) and the \(\Xi_Q(6097)^-\), and the \(\Sigma_Q(2800)^-\) and the \(\Xi'_Q(2930)^-\) are all the 1\(P\)-wave baryons with the spin-parity \(J^P = 3/2^-\) preferably. We also present mass predictions of the unseen bottom baryon \(\Xi_b^0\) in their 1\(P\) and 1\(D\) states, providing some useful clues for the coming experiments to find them, especially the LHCb.

It is noticeable that the relation (2) is derived from the classical relativistic energy and angular momentum of the rotating QCD string model, with no attempt made to obtain quantum correction to it. However, this relation shows the main feature predicted by the quantized theory of the QCD string\([32, 33, 40, 45]\): the linear functional form of trajectory remains intact, only with the intercept and the hadron mass shifted. When taking \(L\) to be the quantized numbers, the approach in this work can be viewed, in a sense, as an leading semi-classical approximation of quantized theory of string. A recent quantum treatment of rotating string\([33]\) in the non-vanishing endpoint-mass case yields a similar conclusion. We also note that for a string tied to one heavy and one light quarks, the mass shift \(M \rightarrow M - M_Q\) in the relation (2) is crucial for describing the moderate nonlinear behavior of the baryon mass squared \(M^2\) as a function of \(L\)[40](see FIGs.6-7) at low-\(L\): such a nonlinearity is absorbed into Eq. (2) largely, since the later takes the form:

\[
M^2 - 2M_0M + M_Q^2 = \pi aL + a_0, \quad (61)
\]

when expanding it in \(M_Q\). Obviously, a nonlinear dependence in \(M^2\) happens in the LHS of Eq. (61) which tends to vanish when \(L\) is large. This is in consistent with the numerical computations in Ref.[40], and is supported by a systematic examination[25] for whole SH hadron systems (the SH mesons and baryons).

In order to compute the spin-dependent mass, we employed the scaling relations based on similarity in the color-configuration between a SH baryon and its meson partner or among the heavy flavor partners. While they are of approximate these relations turn out to be valuable as they have exhibited the most general features of the spin-dependent relativistic corrections, which scale as the magnetic moment \(S_Q/m_Q\) for the \(a_1\)-term and as \(S_Q/M_Q\) for the \(a_2\)-term in Eq.(9). We note that the color-structure similarity among these SH hadrons is implicitly assumed in the quark-diquark picture.

The way, the following remarks are in order:

1. Without adding or tunning of the parameters, a simple application of our computational procedure to the D-wave bottom baryon \(\Lambda_b\) yields a spin-averaged mass and spin-dependent mass splitting which agree well with the observed spin-averaged mass 6149.97MeV of the newly reported resonances \(\Lambda_b\)\([38]\) and its mass splitting \(-3.80\text{MeV}\) and \(2.54\text{MeV}\) for the \(3/2^-\) and \(5/2^-\) states, respectively.

2. By predicting spin-averaged masses, the relation (2) are helpful in itself in identifying the state order of the excited spin-multiplets in the sense of the bisection of the mass intervals. To accommodate them further, detailed computations about the mass differences of the spin-multiplets are necessary.

3. Similar decay behaviors (the pseudoscaler meson emission and relatively narrow widths) seen for the baryons \(\Xi_Q(6227)^-/\Xi_Q(6097)^-\), the \(\Sigma_Q(2800)\)/\(\Xi'_Q(2930)\) prefer to support that they are all the 1\(P\)-wave baryons with \(J^P = 3/2^-\). Further exploring of the parameter \(b\) for them becomes valuable for decoding inner-structures of the \(P\)-wave partners of these baryons.

4. The method in this work can in principle be used to estimate the higher orbital excitations of the bottom baryons, with the experimental mass information of the excited mesons partners or the charmed partners increasing. To go beyond the limitation having to refer to the SH meson mass spectrum in computing the mass splitting, the quantized string dynamics is desirable for further exploring the heavy baryon spectroscopy.

Notes added.– After submission of this work, two newly reported resonances \(\Lambda_b(6146)^0\) and the \(\Lambda_b(6146)^0\)\([38]\) come to our attention, which can be nicely accommodated as the D-wave singly bottom baryons using our approach in this work. The agreement of our prediction with the observed mass data is remarkable.

APPENDIX A

For the orbitally excitations, the classical energy and orbital angular momentum for the rotating QCD string read [28, 40, 43]

\[
E = \frac{m_Q}{\sqrt{1 - v^2_Q}} + \frac{m}{\sqrt{1 - v^2}} + \frac{a}{\omega} \int_0^{\nu_0} du \int_0^{\nu_0} du \frac{du}{\sqrt{1 - u^2}}, \quad (A1)
\]

\[
L = \frac{m_Q^2/\omega}{\sqrt{1 - v^2_Q}} + \frac{m v^2/\omega}{\sqrt{1 - v^2_d}} + \frac{a}{\omega^2} \int_0^{\nu_0} \int_0^{\nu_0} \frac{u^2 du}{\sqrt{1 - u^2}}, \quad (A2)
\]

where \(m_Q\) and \(m\) are the bare masses of the heavy quark \(Q\) and light diquarks \(d\) and \(v_i = \omega_r(i = Q, d)\) the velocity of
the string end tied to the quark \( i = Q,d \). It is known that the
Semel-Wilczek relation (4) follows from upon the \((m,\omega/\alpha)\)-
expansion of (A1) and (A2) [28]. Following [27], we define
the effective (dynamical) masses of the heavy quark and the
light diquark in the CM frame of the baryon by
\[
M_Q = \frac{m_Q}{\sqrt{1 - v_Q^2}}, m_d = \frac{m}{\sqrt{1 - v_d^2}}, \tag{A3}
\]
to rewrite (A1) and (A2) as
\[
E = M_Q + m_d + \frac{a}{\omega} \left[ \arcsin(v_d) + \arcsin(v_Q) \right], \tag{A4}
\]
\[
L = \frac{1}{\omega} (M_Q v_Q^2 + m_d^2) + \frac{a}{2 \omega} \sum_{i=Q,d} \left[ \arcsin(v_i) - v_i \sqrt{1 - v_i^2} \right], \tag{A5}
\]
in which the last term in (A4) is the contribution to the orbital
angular momentum due to the string rotating.
The boundary condition of string at ends with heavy quark gives
\[
\frac{a}{\omega} = \frac{m_Q v_Q}{\sqrt{1 - v_Q^2}} = \frac{M_Q v_Q}{\sqrt{1 - v_Q^2}}, \tag{A6}
\]
or
\[
\frac{a}{\omega} \approx P_Q + \frac{P_Q^3}{2 M_Q^2}, \tag{A7}
\]
with \( P_Q \equiv M_Q v_Q \) the conserved momentum of the heavy
quark. Expanding Eqs. (A3) and (A4) in \( v_Q \) and \( m \) gives, up to \( v_Q^4 \) and the leading order of \( m \),
\[
E = M_Q + m_d + \frac{\pi a}{2 \omega} \left[ v_Q - \frac{m}{m_d} + \frac{1}{6} v_Q^3 \right] + O[v_Q^5], \tag{A8}
\]
\[
\omega L = m_d + M_Q v_Q^2 + \frac{a}{\omega} \left[ \frac{\pi}{4} \frac{m}{m_d} + \frac{a}{3 \omega} v_Q^3 \right] + O[v_Q^5]. \tag{A9}
\]
Using Eq. (A7) and upon eliminating \( \omega \), Eqs.(A8)-(A9)
combines to give, when ignoring the small term \( m/m_d \),
\[
(E - M_Q)^2 = \pi a L + \left( m_d + \frac{P_Q^3}{2 M_Q} \right)^2 - 2 m P_Q. \tag{A10}
\]
This leads to Eq. (2) when taking the bare mass \( m \to 0 \). By
the way, we note that Eq. (3) follows by rewriting the velocity
\( v_Q^2 = 1 - \frac{m_Q}{M_Q} \), with \( m_Q \equiv m_{\text{bare Q}} \) the bare mass of
the heavy quark \( Q \).
Note that the heavy quark limit(HQL) is defined as the
largeness of the bare mass \( m_Q \) of the heavy quark \( Q \) enter-
ing the QCD Lagrangian while its 3-momentum \( P_Q = M_Q v_Q \)
remains fixed as \( Q \) behaves like a static external source[29]
within the bound state of hadrons. It follows from Eq. (A3)
that in the HQL the effective mass \( M_Q \) tends to infinity also
while the 3-velocity \( v_Q \) tends to vanish, that is, the heavy
quarks move nonrelativistically within hadrons, as it should be.
One can readily check that in the HQL, Eqs. (A8) and
(A9) become \( E = M_Q + m_d + \frac{\pi a}{2 \omega} \) and \( \omega L = m_d + \frac{\pi a}{4 \omega} \), which yield \( (E - M_Q)^2 = \pi a L + m_d^2 \). Here, \( M_Q v_Q^2 = P_Q^2/M_Q \) tends to
vanish in the RHS of Eq. (A9).

APPENDIX B

For the heavy quark-diquark systems, the matrix elements of \( L \cdot S_i \) can be calculated by explicit construction of the
baryon states with a given \( J_1 \) as linear combinations of the states \( |S_{13}, S_Q, L_1 \rangle \) with \( S_{13} + S_Q + L_3 = J_1 \). Due to the
rotation invariance of the matrix elements, it suffices to use a
single \( J_1 \) for each and, one can use
\[
L \cdot S_i = \frac{1}{2} \left( L_1 S_{13} + L_2 S_{12} + L_3 S_{13} \right), \tag{B1}
\]
to find their elements by applying \( L \cdot S_i \) on the third compo-
nents of angular momenta. In the rep. of \( |L_1, S_Q, S_{13} \rangle \) these
component are given by the following basis states [42]
\[
|1^2 P_{1/2}, J_1 = 1/2 \rangle = \frac{\sqrt{5}}{3} |1, -1/2, 0 \rangle - \frac{1}{3} |0, 1/2, 0 \rangle
- \frac{\sqrt{5}}{3} |0, -1/2, 1 \rangle + \frac{2}{3} |1, -1/2, 1 \rangle,
\]
\[
|1^4 P_{1/2}, J_1 = 1/2 \rangle = \frac{1}{\sqrt{2}} |1, 1/2, -1 \rangle - \frac{1}{3} |1, -1/2, 0 \rangle
- \frac{\sqrt{5}}{3} |0, 1/2, 0 \rangle + \frac{1}{3} |0, -1/2, 1 \rangle
+ \frac{1}{3 \sqrt{2}} |1, 1/2, 1 \rangle,
\]
\[
|1^2 P_{3/2}, J_1 = 3/2 \rangle = \frac{2}{3} \sqrt{7/3} |1, -1/2, 1 \rangle - \frac{1}{3} |0, 1/2, 1 \rangle,
\]
\[
|1^4 P_{3/2}, J_1 = 3/2 \rangle = \frac{3}{5} \sqrt{11/15} |1, 1/2, 0 \rangle - \frac{2}{\sqrt{15}} |1, -1/2, 1 \rangle
- \frac{2}{\sqrt{15}} |0, 1/2, 1 \rangle,
\]
\[
|1^4 P_{5/2}, J_1 = 5/2 \rangle = |1, 1/2, 1 \rangle.
\]
Having these component states (in \( L - S \) coupling), one can
compute the matrix elements of \( L \cdot S_i \),
\[
\langle L \cdot S_i \rangle_{J_1 = \frac{3}{2}} = \begin{bmatrix}
-\frac{4}{3} & -\frac{\sqrt{3}}{3} \\
-\frac{\sqrt{3}}{3} & -\frac{8}{3}
\end{bmatrix}, \tag{B1}
\]
\[
\langle L \cdot S_i \rangle_{J_1 = \frac{5}{2}} = \begin{bmatrix}
\frac{2}{3} & -\frac{\sqrt{5}}{3} \\
-\frac{\sqrt{5}}{3} & -\frac{8}{3}
\end{bmatrix}. \tag{B2}
\]

Accordingly, the states in terms of the \( J - j \) coupling can be
expressed as linear combinations of states with definite \( L - S \)
coupling (for each eigenvalue \( \lambda \) of \( L \cdot S_{13} \)) [42]:
\[
\lambda = -2 : \langle J = \frac{1}{2}, j = 0 \rangle = \sqrt{\frac{5}{3}} |1^2 P_{1/2} \rangle + \sqrt{\frac{2}{3}} |1^4 P_{1/2} \rangle, \tag{B3}
\]
\[
\lambda = -1 : \langle J = \frac{3}{2}, j = 1 \rangle = \sqrt{\frac{7}{5}} |1^2 P_{3/2} \rangle + \sqrt{\frac{2}{15}} |1^4 P_{3/2} \rangle,
\]
\[
\lambda = 0 : \langle J = \frac{5}{2}, j = 1 \rangle = \sqrt{\frac{11}{25}} |1^2 P_{5/2} \rangle + \sqrt{\frac{1}{15}} |1^4 P_{5/2} \rangle,
\]
\[
\lambda = 1 : \langle J = \frac{7}{2}, j = 2 \rangle = \sqrt{\frac{13}{25}} |1^2 P_{7/2} \rangle + \sqrt{\frac{1}{15}} |1^4 P_{7/2} \rangle,
\]
\[
\lambda = 2 : \langle J = \frac{9}{2}, j = 2 \rangle = \sqrt{\frac{17}{25}} |1^2 P_{9/2} \rangle + \sqrt{\frac{1}{15}} |1^4 P_{9/2} \rangle.
\]
\[ \lambda = -1 : |J = \frac{1}{2}, J = 1\rangle = \sqrt{\frac{2}{3}}(1^2 P_{1/2}) - \sqrt{\frac{1}{3}}|1^4 P_{1/2}\rangle, \quad (B4) \]

\[ \lambda = -1 : |J = \frac{3}{2}, j = 1\rangle = \sqrt{\frac{1}{6}}|1^2 P_{3/2}\rangle + \sqrt{\frac{5}{6}}|1^4 P_{3/2}\rangle, \quad (B5) \]

\[ \lambda = +1 : |J = \frac{3}{2}, j = 2\rangle = \sqrt{\frac{5}{6}}|1^2 P_{3/2}\rangle - \sqrt{\frac{1}{6}}|1^4 P_{3/2}\rangle, \quad (B6) \]

\[ \lambda = +1 : |J = \frac{5}{2}, j = 2\rangle = |1^4 P_{3/2}\rangle, \quad (B7) \]

which can be used to average \( \mathbf{L} \cdot \mathbf{S}_Q \) and \( \mathbf{S}_{12} \). The detailed results are collected in Table X.

### APPENDIX C

We describe here some of the details on how to estimate the values of the parameters \( a_1, a_2, b, c \) that enter the spin-dependent interaction (9) for the SH mesons where \( \mathbf{S}_Q \) is replaced everywhere in Appendix C by the spin \( \mathbf{S}_g \) of light quark. The following three cases of excited states are considered in order:

1. The S-wave SH mesons. In this ground-state case, only the contact term \( c \mathbf{S}_Q \cdot \mathbf{S}_g \) remains in the spin-dependent interaction (9). Since the expectation values of \( \mathbf{S}_Q \cdot \mathbf{S}_g \) are \(-3/4\) and \(1/4\) in the \(1^1 S_0\) and \(1^3 S_1\) meson states, respectively, the parameter \( c \) can be estimated simply by confronting the predicted mass difference between two \( S \)-states, \( c(1/4 - 3/4) = c \), with the measured S-wave masses of the \( D \) mesons in the Table VI. The result is

\[ c = (2010.3 - 1869.7) \text{MeV} = 140.6 \text{MeV}. \quad (C1) \]

2. The P-wave SH mesons. Similar to Appendix B, a calculation can be performed for the P-wave SH mesons. As in the case of the SH baryons, we find it convenient to work in the \( j - j \) basis in which the analogue of the first term in Eq.(9), \( a_1 \mathbf{L} \cdot \mathbf{S}_f \), is diagonal. We first calculate the expectation values of \( \mathbf{L} \cdot \mathbf{S} \) and the tensor operator \( \mathbf{S}_{12} \) in the basis states \( 3^5 P_1 \). The results are shown in Table XI.

### TABLE XI: Expectation values of the spin-dependent terms for P-wave \( cQ \) mesons in the \( L - S \)-coupling basis states.

| State | \( \langle \mathbf{L} \cdot \mathbf{S} \rangle \) | \( \langle \mathbf{S}_{12} \rangle \) | \( \langle \mathbf{S}_Q \cdot \mathbf{S}_g \rangle \) |
|-------|-----------------|-----------------|-----------------|
| \( 1^3 P_0 \) | -2 | -4 | 1/4 |
| \( 1^3 P_1 \) | 0 | 0 | -3/4 |
| \( 3^3 P_1 \) | -1 | 2 | 1/4 |
| \( 3^3 P_2 \) | 1 | -2/5 | 1/4 |

To evaluate the expectation values of \( \mathbf{L} \cdot \mathbf{S}_i(i = a, Q) \), it is convenient to use the \( L - S \) basis. When labelling the states by \( |S_{q3}, S_{Q3}, L_3\rangle \), one can construct the \( L - S \) basis by

\[ |3^1 P_0, J_3 = 0\rangle = \left| -\frac{1}{2}, -\frac{1}{2}, 1\right\rangle, \quad (C2) \]

\[ |3^1 P_1, J_3 = 1\rangle = \left| \frac{1}{\sqrt{2}}, \frac{1}{\sqrt{2}}, 1\right\rangle - \left| -\frac{1}{2}, -\frac{1}{2}, 1\right\rangle, \quad (C3) \]

\[ |3^1 P_1, J_3 = 1\rangle = \left| \frac{1}{\sqrt{2}}, \frac{1}{\sqrt{2}}, 1\right\rangle + \left| \frac{1}{2}, -\frac{1}{2}, 1\right\rangle - \frac{1}{\sqrt{2}}\left| \frac{1}{2}, -\frac{1}{2}, 0\right\rangle, \quad (C4) \]

\[ |3^1 P_2, J_3 = 2\rangle = \left| \frac{1}{2}, -\frac{1}{2}, 1\right\rangle. \quad (C5) \]

Using (B1) in the \( J = 1 \) subspace given by the basis \( 3^1 P_1, 3^3 P_1 \), the matrices describing mixing of the \( J = 1 \) states are

\[ \langle L \cdot S_Q \rangle_{J=1} = \begin{bmatrix} 0 & 1/\sqrt{2} \\ 1/\sqrt{2} & -1/2 \end{bmatrix}, \quad (C6) \]

\[ \langle L \cdot S_Q \rangle_{J=1} = \begin{bmatrix} 0 & -1/\sqrt{2} \\ -1/\sqrt{2} & -1/2 \end{bmatrix}. \quad (C7) \]

The first matrix, which has the eigenvalues \(-1/2\) and \(-1/2\), can be diagonalized by transforming the \( L - S \) eigenstates to the \( |J, J\rangle \) eigenstates. This transformation, when written in the whole space, can be given by

\[ | J = 0, j = 1/2\rangle = |3^1 P_0\rangle, \]

\[ | J = 1, j = 1/2\rangle = \left| \frac{1}{2} |1^3 P_1\rangle - \frac{2}{3} |3^3 P_1\rangle, \right. \]

\[ | J = 1, j = 3/2\rangle = \left| \frac{2}{3} |1^3 P_1\rangle + \frac{1}{3} |3^3 P_1\rangle, \right. \]

\[ | J = 2, j = 3/2\rangle = |3^3 P_2\rangle. \]

With the expressions above one can work out the expectation values of all spin-dependent operators contributing to the masses of the P-wave \( Q\bar{q} \) mesons and thereby obtain estimations for the spin-dependent mass splitting via expanding around the eigenstates of \( J = L + S_Q \). Including the spin-averaged mass \( \bar{M} \), the results for the P-wave are [35],

\[ M(0, 1/2) = \bar{M} - a_1 - a_2 - b - \frac{c}{4}, \quad (C8) \]

\[ M(1, 1/2) = \bar{M} - a_1 + \frac{1}{3} a_2 + \frac{1}{3} b - \frac{c}{12}, \quad (C9) \]

\[ M(1, 3/2) = \bar{M} + \frac{1}{2} a_1 - \frac{5}{6} a_2 + \frac{1}{6} b - \frac{5c}{12}, \quad (C10) \]
Given Eqs. (C8-C11), the parameters \((a_1, a_2, b)\) which reproduce the observed masses of the \(c\bar{s}\) mesons in Table VI are\[35\]

\[
\begin{align*}
    \tilde{M}(\text{MeV}), & \quad a_1(\text{MeV}), \quad a_2(\text{MeV}) \quad b(\text{MeV}) \\
    2513.4, & \quad 89.4, \quad 40.7, \quad 65.6,
\end{align*}
\]

where the parameter \(c\) in the hyperfine term is taken to be zero as it is quite small in the P-wave state.

(3) The D-wave \(S\) mesons. The similar procedure applies for the D-wave \(Q\bar{q}\) mesons. Using the state \(|S_{\bar{q}3}, S_{\bar{Q}3}, L_3\rangle\), one can explicitly construct the \(L - S\) basis for the D-wave \(Q\bar{q}\) states by

\[
|\hat{J}D_1, J_3 = 1\rangle = \sqrt{\frac{2}{5}} \left| -\frac{1}{2}, -\frac{1}{2}, 2 \right\rangle + \sqrt{\frac{1}{10}} \left| \frac{1}{2}, \frac{1}{2}, 0 \right\rangle
\]

- \(\sqrt{\frac{3}{20}} \left| -\frac{1}{2}, \frac{1}{2}, 1 \right\rangle - \sqrt{\frac{3}{20}} \left| \frac{1}{2}, \frac{1}{2}, 1 \right\rangle\),

\[
|\hat{J}D_2, J_3 = 2\rangle = \frac{1}{\sqrt{2}} \left| -\frac{1}{2}, -\frac{1}{2}, 2 \right\rangle - \frac{1}{\sqrt{2}} \left| \frac{1}{2}, \frac{1}{2}, 2 \right\rangle\),

\[
|\hat{J}D_3, J_3 = 3\rangle = \left| \frac{1}{2}, \frac{1}{2}, 2 \right\rangle.
\]

Utilizing (B1) again in the \(J = 2\) subspace given by the basis \(|\hat{J}D_2, \hat{J}D_2\rangle\), the matrices describing mixing of the \(J = 2\) states are

\[
\begin{align*}
    \langle L \cdot S_q \rangle_{j=2} &= \left[ \begin{array}{cc} 0 & \sqrt{3/2} \\ \sqrt{3/2} & -1/2 \end{array} \right], \\
    \langle L \cdot S_Q \rangle_{j=2} &= \left[ \begin{array}{cc} 0 & -\sqrt{3/2} \\ -\sqrt{3/2} & -1/2 \end{array} \right].
\end{align*}
\]

The first matrix, which has the eigenvalues \(-3/2\) and \(1\), can be diagonalized by the following basis transformation between the \(L-S\) eigenstates and the \(|\hat{J}, \hat{j}\rangle\) eigenstates. In the whole space, the transformation takes the form:

\[
|J = 1, j = 3/2\rangle = |\hat{J}D_1\rangle,
\]

\[
|J = 2, j = 3/2\rangle = |\sqrt{2/5}|P_2\rangle - |\sqrt{3/5}|P_2\rangle,
\]

\[
|J = 2, j = 5/2\rangle = \sqrt{\frac{3}{5}}|P_2\rangle + \sqrt{\frac{2}{5}}|P_2\rangle,
\]

\[
|J = 3, j = 5/2\rangle = |\hat{3}P_3\rangle.
\]

Given these relations, the calculations for the expectation values of all mass splitting operators can be performed and the mass expression for the D-wave \(Q\bar{q}\) mesons can be obtained via the procedure similar to that to have Eqs.(16)-(20). The results are

\[
M(1, 3/2) = \tilde{M} - \frac{3}{2} a_1 - \frac{3}{2} a_2 - \frac{5}{2} b + \frac{c}{4},
\]

\[
M(2, 3/2) = \tilde{M} + \frac{9}{10} a_1 + \frac{3}{2} a_2 + \frac{3}{2} b - \frac{3c}{2},
\]

\[
M(2, 5/2) = \tilde{M} + a_1 + \frac{9}{5} a_2 + \frac{7}{5} b - \frac{7c}{20},
\]

\[
M(3, 5/2) = \tilde{M} + a_1 + a_2 - b - \frac{c}{4}.
\]

In the D-wave case, only two observed masses are available in Table VI for each family of the \(D/D_s\) mesons. Since only the mass splitting \(\Delta M = M - \tilde{M}\) is relevant here, we use the mass splitting \(\Delta M\) given by the quark model(QM) predictions\[34\] rescaled by the deviation factor 2.04 so that the rescaled mass splitting match the observed data. The details are listed in Table XII. The parameters for the D-wave \(D\) mesons which reproduce the mass splitting \(\Delta M\)(rescaled) in Table VIII are

\[
\begin{align*}
    \left\{ a_1(\text{MeV}), \quad a_2(\text{MeV}) \quad b(\text{MeV}) \right\} = \left\{ 47.6, \quad 12.6, \quad 0.52, \right\}
\end{align*}
\]

where the parameter \(c\) in the hyperfine term has been set to be zero. This completes the estimation of \(a_2\) for the \(S\) mesons in their P-wave and D-wave excitations.
