Regularity at the Free Boundary for
Dirac-Harmonic Maps from Surfaces

Ben Sharp∗ and Miaomiao Zhu†

May 7, 2014

Abstract

We establish the regularity theory for certain critical elliptic systems with an anti-symmetric structure under inhomogeneous Neumann and Dirichlet boundary constraints. As applications, we prove full regularity and smooth estimates at the free boundary for weakly Dirac-harmonic maps from spin Riemann surfaces. Our methods also lead to the full interior $\epsilon$-regularity and smooth estimates for weakly Dirac-harmonic maps in all dimensions.

1 Introduction

Motivated by the supersymmetric nonlinear sigma model from quantum field theory [9, 23], a variational problem that couples a map between two Riemannian manifolds with a spinor field along this map is introduced in [5]. More precisely, let $(M,g_M)$ be a spin Riemannian manifold of dimension $m \geq 2$, $\Sigma M$ the spinor bundle over $M$ and $(N,g)$ a compact Riemannian manifold of dimension $d$. Let $\phi$ be a map from $M$ to $N$ and $\psi$ a section of the twisted bundle $\Sigma M \otimes \phi^{-1}TN$. Using the connection $\nabla$ which is induced from the spin connection on $\Sigma M$ and the pull back Levi-Civita connection on $\phi^{-1}TN$, one defines the Dirac operator $D$ along the map $\phi$ by $D\psi := \gamma_\alpha \nabla_{\gamma_\alpha} \psi$, where $\gamma_\alpha$ is a local orthonormal frame on $M$ and “·” is the Clifford multiplication. Consider the functional

$$L(\phi, \psi) = \int_M (|d\phi|^2 + \langle \psi, D\psi \rangle) \, dV_{g_M}.$$  \hfill (1.1)

Critical points $(\phi, \psi)$ of (1.1) are called Dirac-harmonic maps from $M$ to $N$. Mathematically, Dirac-harmonic maps generalise the notions of harmonic maps and harmonic spinors, both of which have been extensively studied from various geometric and analytic points of view. Analytically, the Euler-Lagrange system of (1.1) couples a second order critical elliptic equation with a first order Dirac-type equation. In dimension $m = 2$, the functional (1.1) is conformally invariant in the domain as is the case for harmonic maps, which places the study of Dirac-harmonic maps in the framework of two dimensional conformally invariant variational problems, where a lot of powerful geometric analysis techniques have been developed, allowing for a deep investigation of the regularity theory for weak solutions.

Exploring the geometric and analytic aspects of this variational problem, Chen-Jost-Wang-Zhu [7] introduced an appropriate boundary value problem for Dirac-harmonic maps from a spin Riemann

e-mail: Miaomiao.Zhu@mis.mpg.de
surface $M$ with non-empty boundary $\partial M$ into a compact Riemannian manifold $N$, providing a mathematical interpretation of the supersymmetric nonlinear sigma model with boundaries [4] and the D-branes in superstring theory [27]. More precisely, let $S$ be a closed $s$-dimensional submanifold of $N$, then the map $\phi$ is supposed to satisfy the classical free boundary condition:

$$\phi(\partial M) \subset S,$$

while the spinor field $\psi \in \Gamma(\Sigma M \otimes \phi^{-1}TN)$ is required to satisfy a chirality type (local elliptic) boundary condition that is compatible with $\phi$ as well as the supporting submanifold $S$:

$$B^\pm_\phi \psi|_{\partial M} = 0, \quad (1.2)$$

generalising the usual chirality (local elliptic) boundary condition $B^\pm \bar{\psi}|_{\partial M} = 0$ introduced by Gibbons-Hawking-Horowitz-Perry [14] (we refer to [20] for the mathematical setting) for usual spinors $\bar{\psi} \in \Gamma(\Sigma M)$.

Embed $N$ isometrically into some Euclidean space $\mathbb{R}^n$ and consider admissible fields for (1.1) in the following space

$$\mathcal{X}_{1,4}^{1,2}(M, N; S) := \left\{ (\phi, \psi) \in H^1(M, N) \times W^{1,4}(\Sigma M \otimes \phi^{-1}TN) : \phi(x) \in S \text{ and } B^\pm_\phi \psi(x) = 0 \text{ for a.e. } x \in \partial M \right\}.$$

One can easily verify that the functional (1.1) extends to $\mathcal{X}_{1,4}^{1,2}(M, N; S)$. Critical points $(\phi, \psi) \in \mathcal{X}_{1,4}^{1,2}(M, N; S)$ of (1.1) are called weakly Dirac-harmonic maps from $M$ to $N$ with free boundary $\phi(\partial M)$ on $S$.

To study the regularity at the free boundary for weakly Dirac-harmonic maps from spin Riemann surfaces, by conformal invariance in dimension $m = 2$, one can locate the problem in a small neighbourhood of a boundary point and consider the model case that the domain is the upper half unit disc

$$B_1^+ := \left\{ (x_1, x_2) \in \mathbb{R}^2 | x_1^2 + x_2^2 < 1, x_2 \geq 0 \right\}$$

equipped with the Euclidean metric and the free boundary portion is

$$I := \left\{ (x_1, 0) \in \mathbb{R}^2 | -1 < x_1 < 1 \right\}.$$

Denote by $\vec{n}$ the outward unit normal vector field on the boundary portion $I$.

As in [7], applying a reflection procedure for $\phi$ analogous to that used in the free boundary problem for harmonic maps [16, 32] and introducing a reflection for $\psi$ that is compatible with the boundary condition (1.2), one can extend the two fields across $I$ to the whole ball $B_1$ such that the extended fields $(\bar{\phi}, \bar{\psi})$ weakly solve a critical elliptic system with an anti-symmetric structure similar to that introduced by Rivièrè [29] and Rivièrè-Struwe [30] up to an additional frame transformation which can be analytically well controlled. By adapting the regularity theory of Rivièrè-Struwe, they proved the following regularity results:

**Theorem 1.1** ([14], Theorem 1.1-1.2). Let $M$ be a compact spin Riemann surface with boundary $\partial M$, $N$ a compact Riemannian manifold with $S \subset N$ a closed totally geodesic submanifold of $N$. Let $(\phi, \psi)$ be a weakly Dirac-harmonic map from $M$ to $N$ with free boundary $\phi(\partial M)$ on $S$. Then there exists some $\beta \in (0, 1)$ such that $\phi \in C^{1,\beta}(M, N)$ and $\psi \in C^{1,\beta}(\Sigma M \otimes \phi^{-1}TN)$.

In the present paper, we prove the full regularity at the free boundary - without assuming that $S \subset N$ is totally geodesic - by establishing the regularity theory for critical elliptic systems with an anti-symmetric structure under inhomogeneous Neumann and Dirichlet boundary constraints, extending the classical boundary regularity theory for sub-critical elliptic PDE studied by Agmon-Douglas-Nirenberg [2, 3]. It provides the boundary regularity results related to the recent interior
regularity theory for critical elliptic systems with an anti-symmetric structure developed by Riviè\` re [29], Rivièr\`e-Struwe [30], Sharp-Topping [37], Sharp [36, 35] and Zhu [42].

To state our main PDE result, let $1 \leq k \in \mathbb{N}$, $1 \leq p \in \mathbb{R}$ and $U \subset \mathbb{R}^m$, $m \geq 2$ be some open set with $T \subset \partial U$ a smooth boundary portion, define the space (see e.g. [40])

$$W^k_p(T) := \{ g \in L^1(T) : g = G|_T \text{ for some } G \in W^{k,p}(U) \}$$

with norm

$$\| g \|_{W^k_p(T)} = \inf_{G \in W^{k,p}(U), G|_T = g} \| G \|_{W^{k,p}(U)}.$$ 

Then we have

**Theorem 1.2.** Let $d \geq 2$, $0 \leq s \leq d$, $0 < \Lambda < \infty$ and $1 < p < 2$. For any $A \in L^\infty \cap W^{1,2}(B^+_1, GL(d))$, $\Omega \in L^2(B^+_1)$, $\mathbf{s}(d) \otimes \Lambda^1(\mathbb{R}^m)$, $f \in L^p(B^+_1, \mathbb{R}^d)$, $(g, \mathbf{t}) \in (W^{1,p}(I, \mathbb{R}^s), W^{2,p}(I, \mathbb{R}^{d-s}))$ and for any $u \in W^{1,2}(B^+_1, \mathbb{R}^d)$ weakly solving

$$d^*(Adu) = (\Omega, Adu) + f \quad \text{in} \quad B^+_1,$$

$$\frac{\partial u^i}{\partial n} = g^i \quad \text{on} \quad I \quad 1 \leq i \leq s,$$

$$u^j = \mathbf{t}^j \quad \text{on} \quad I \quad s + 1 \leq j \leq d,$$

with

$$\Lambda^{-1} |\xi| \leq |A(x)\xi| \leq \Lambda |\xi| \quad \text{for a.e. } x \in B^+_1, \quad \text{for all } \xi \in \mathbb{R}^d$$

and satisfying the compatibility condition that $A(x)$ commutes with $R$ for a.e. $x \in B^+_1$ where

$$R = (R^j_j) := \begin{pmatrix} I_{d_s} & 0 \\ 0 & -I_{d-d_s} \end{pmatrix}.$$ 

Then $u \in W^{2,p}_\text{loc}(B^+_1 \cup I)$ and there exist $\epsilon = \epsilon(d, \Lambda, p) > 0$ and $C = C(d, \Lambda, p) > 0$ such that whenever

$$\| \Omega \|_{L^2(B^+_1)} + \| \nabla A \|_{L^2(B^+_1)} \leq \epsilon,$$

then

$$\| \nabla^2 u \|_{L^p(B^+_1)} + \| \nabla u \|_{L^{2,p}(B^+_1)} \leq C(\| u \|_{L^1(B^+_1)} + \| f \|_{L^p(B^+_1)} + \| g \|_{W^{1,p}((I))} + \| \mathbf{t} \|_{W^{2,p}(I)}).$$

**Remark 1.3.** Theorem 1.2 says that for the boundary conditions above, under the appropriate assumptions on $A$ and $\Omega$, the solution $u$ behaves like that of the following classical boundary value problem (for a scalar-valued $u$)

$$-\Delta u = f \quad \text{in} \quad B^+_1,$$

$$\frac{\partial u}{\partial n} = g \quad \text{on} \quad I \quad \text{or} \quad u = \mathbf{t} \quad \text{on} \quad I,$$

studied by Agmon-Douglis-Nirenberg [2], where $f \in L^p(B^+_1)$, $g \in W^{1,p}(I)$, $\mathbf{t} \in W^{2,p}(I)$ and $p > 1$.

**Remark 1.4.** Clearly if $s = 0$ or $s = d$, then the condition that $A$ commutes with $R = \pm Id$ holds trivially. We remark here what it means for $u$ to be a weak solution to such a problem: setting

$$\mathbf{G} := (g^1, \ldots, g^s, 0, \ldots, 0),$$

and noticing that $A$ commutes with $R$ if and only if $A$ has the following block form:

$$A = \begin{pmatrix} A_s & 0 \\ 0 & A_{d-s} \end{pmatrix},$$

then for any $\psi \in C_c^\infty$ we have

$$-\int_{B^+_1} \nabla u \nabla \psi \, dx + \int_{\partial B^+_1} g \psi \, dS = \int_{B^+_1} f \psi \, dx.$$
then we say that \( u \) is a weak solution to (1.3), (1.4) and (1.5) if for any \( \eta \in C_c^\infty(B_1^+ \cup I, \mathbb{R}^d) \) such that

\[
\eta^j = 0 \quad \text{on } I, \quad s + 1 \leq j \leq d
\]

then

\[
\int_{B_1^+} (Adu, d\eta) = \int_{B_1^+} (\langle \Omega, Adu \rangle + f, \eta) + \int_I (A\mathcal{S}, \eta),
\]

with

\[
u^i = t^i \quad \text{on } I \text{ in a trace sense, } \ s + 1 \leq i \leq d.
\]

**Remark 1.5.** When the boundary conditions are homogeneous, namely \( g \equiv 0 \) and \( \varpi \equiv 0 \), we have an extension of Theorem 1.2 to the case of higher dimensional domains \( B_1^+ \subset \mathbb{R}^m \) for \( m \geq 2 \) with \( \Omega, \nabla A \) and \( \nabla u \) in the Morrey space \( M^{2,m-2} \) and \( f \in L^p \) with \( \frac{m}{2} < p < m \) (see Section 2, Theorem 2.7).

Now, going back to Dirac-harmonic maps, it is possible to use the known interior regularity [7, 39] to prove that we can localise our problem also in the target - see Lemma 4.4. This allows us to use the so called Fermi coordinates about \( S \) at which point we use elementary geometric arguments to show that our map \( \phi \) weakly solves an elliptic system of the form (1.3) with boundary conditions (1.4) and (1.5) but only for \( p = 1 \). More precisely we have

\[
|\Omega(x)| + |\nabla A(x)| \leq C|\nabla \phi(x)| \quad \text{for a.e. } x \in B_1^+
\]

and

\[
|f(x)| \leq C|\psi(x)|^2|\nabla \phi(x)| \quad \text{for a.e. } x \in B_1^+
\]

Moreover the tangent components of the map \( \phi \) satisfy an inhomogeneous Neumann condition

\[
\left( \frac{\partial \phi^i}{\partial n} \right) = \text{Re}(P_S^2(\tilde{\mathbf{n}} \cdot \psi^i; \psi^\top)) \quad \text{on } I, \quad \text{for } 1 \leq i \leq s
\]

\( (P_S(\cdot; \cdot)) \) is a spinorial extension of the shape operator \( P_S(\cdot; \cdot) \) of \( S \) in \( N \), see section 3.2) and the normal components satisfy a homogeneous Dirichlet condition

\[
\phi^i = 0 \quad \text{on } I, \quad \text{for } s + 1 \leq i \leq d.
\]

A-priori \( \psi \in W^{1,\frac{2}{3}} \hookrightarrow L^4 \) and \( \phi \in W^{1,2} \) hence we have

\[
f \in L^1(B_1^+), \quad \text{Re}(P_S^2(\tilde{\mathbf{n}} \cdot \psi^i; \psi^\top)) \in W_{\partial}^{1,1}(I).
\]

In order to be able to apply the regularity result in Theorem 1.2, we need to improve the regularity up to the boundary for the spinor field \( \psi \) so that

\[
f \in L^p(B_1^+), \quad \text{Re}(P_S^2(\tilde{\mathbf{n}} \cdot \psi^i; \psi^\top)) \in W_{\partial}^{1,p}(I), \quad \text{for some } p > 1.
\]

Fortunately, this can be achieved by investigating the Dirac equation for \( \psi \) as well as observing that the chirality boundary condition (1.2) on the spinor is essentially a simple Riemann-Hilbert boundary condition for the Cauchy-Riemann operator (see Section 4) and hence standard PDE estimates allow us to consider our map \( \phi \) as above but this time for some \( 1 < p < 2 \) and Theorem 1.2 yields, in particular, that \( \nabla \phi \in L^p \) up to the boundary for some \( r > 2 \). At this point we are considering a sub-critical and classical boundary value problem and a simple bootstrapping argument concludes:

**Theorem 1.6.** Let \( N \) be a compact Riemannian manifold, \( S \subset N \) a closed submanifold with \( (\phi, \psi) \) a weakly Dirac-harmonic map from \( B_1^+ \) to \( N \) with free boundary \( \phi(I) \) on \( S \). Then for any \( k \in \mathbb{N} \) there exist \( \epsilon = \epsilon(N, S, \|\psi\|_{L^4(B_1^+))} > 0 \) and \( C = C(k, N, S) > 0 \) such that if

\[
\|\nabla \phi\|_{L^2(B_1^+)} \leq \epsilon,
\]
then
\[ \|\nabla^k \phi\|_{L^\infty(B_1^+)} + \|\nabla^k \psi\|_{L^\infty(B_1^+)} \leq C \|\nabla \phi\|_{L^2(B_1^+)}(1 + \|\psi\|_{L^4(B_1^+)}) \].

**Remark 1.7.** We can be more precise about the dependency of \( \epsilon \) on \( \|\psi\|_{L^4(B_1^+)} \) in the above theorem: in particular there exists a uniform constant \( \hat{r} = \hat{r}(N, \mathcal{S}) > 0 \) such that one can take

\[ \epsilon = \frac{\hat{r}}{C(N)(1 + \|\psi\|_{L^4(B_1^+)})} \]

for some \( C(N) > 0 \) - see Lemma 4.4 and Remark 4.5.

By the conformal invariance of the problem and re-scaling in the domain coupled with the known interior regularity [7, 39], we trivially establish the full regularity at the free boundary:

**Theorem 1.8.** Let \( M \) be a compact spin Riemann surface with boundary \( \partial M \), \( N \) a compact Riemannian manifold, and \( \mathcal{S} \subset N \) a closed submanifold. Let \((\phi, \psi)\) be a weakly Dirac-harmonic map from \( M \) to \( N \) with free boundary \( \phi(\partial M) \) on \( \mathcal{S} \). Then \((\phi, \psi)\) is smooth up to the boundary.

**Remark 1.9.** Any weakly harmonic map or weakly minimal surface \( u : B_1^+ \rightarrow N \) with a free boundary \( u(I) \subset \mathcal{S} \) is also a weakly Dirac-harmonic map when coupled with the zero spinor field. Therefore we can apply Theorems 1.6 and 1.8 to obtain the regularity at the boundary in this case. The free boundary value problem is simpler for harmonic maps and minimal surfaces since one has zero Neumann conditions for the tangential components as well as zero Dirichlet conditions for the normal components - geometrically this is known as the transversality property at the free boundary (see e.g. [19, 16]): \( \frac{\partial u}{\partial n} \perp \mathcal{S} \), a.e. on \( I \).

Using the PDE results from this paper we also obtain the following local smooth interior estimates for weakly Dirac-harmonic maps in all dimensions \( m \geq 2 \). Denote by \( B_1 \subset \mathbb{R}^m \) the unit ball.

**Theorem 1.10.** For \( m = 2 \). Let \( N \) be a compact Riemannian manifold and \((\phi, \psi)\) a weakly Dirac-harmonic map from the unit disc \( B_1 \subset \mathbb{R}^2 \) into \( N \). For any \( k \in \mathbb{N} \) there exist \( \epsilon = \epsilon(N) > 0 \) and \( C = C(k, N) > 0 \) such that if

\[ \|\nabla \phi\|_{L^2(B_1)} \leq \epsilon, \]
then
\[ \|\nabla^k \phi\|_{L^\infty(B_1^+)} + \|\nabla^k \psi\|_{L^\infty(B_1^+)} \leq C \|\nabla \phi\|_{L^2(B_1)}(1 + \|\psi\|_{L^4(B_1)}). \]  

**Remark 1.11.** In dimension \( m = 2 \), the local smooth interior estimates as in (1.7) were obtained in [6] using classical methods but for smooth Dirac-harmonic maps and assuming also that \( \|\psi\|_{L^4(B_1)} \leq \epsilon \).

**Theorem 1.12.** Let \( m \geq 3 \) and \( N \) be a compact Riemannian manifold. For any \( k \in \mathbb{N} \), there exist \( \epsilon = \epsilon(m, N) > 0 \) and \( C = C(m, N, k) > 0 \) such that if \((\phi, \psi)\) is a weakly Dirac-harmonic map from the unit ball \( B_1 \subset \mathbb{R}^m \) into \( N \) (see Section 3 for a definition) satisfying

\[ \|\nabla \phi\|_{M^{2,m-2}(B_1)} + \|\psi\|_{M^{4,m-2}(B_1)} \leq \epsilon, \]
then
\[ \|\nabla^k \phi\|_{L^\infty(B_1^+)} + \|\nabla^k \psi\|_{L^\infty(B_1^+)} \leq C(\|\nabla \phi\|_{M^{2,m-2}(B_1)} + \|\psi\|_{M^{4,m-2}(B_1)}), \]
where the Morrey norms appearing here are defined in appendix B.

**Remark 1.13.** We can conclude the same results as in Theorem 1.12 for weakly Dirac-harmonic maps from \((B_1, g_1)\) equipped with a spin structure into \( N \), where \( g_1 \) is some smooth Riemannian metric. This is because the crucial improvement to the regularity comes from Theorem 2.1, thus taking into account remark 2.5 and equation (3.8) we can essentially apply the same proof. We also mention that this recovers the \( \epsilon \)-regularity estimates for weakly harmonic maps (setting \( \psi \equiv 0 \)).
Remark 1.14. Under the smallness assumption (1.8), the regularity for weakly Dirac-harmonic maps was proved by Wang-Xu [39] using a different method. More precisely, they first derive the Hölder continuity for \( \phi \) by combining Hélein’s technique of moving frames [18] for harmonic maps and Riviè re-Struwe’s Coulomb gauge theorem in the Morrey space setting [30], and then obtain the \( C^{1,\alpha} \)-regularity for \((\phi, \psi)\) by adapting the hole-filling-type argument by Giaquinta-Hildebrandt [15] for harmonic maps. Finally, the higher order regularity follows from the standard bootstrapping argument.

Remark 1.15. We also point out here that it is possible to prove these estimates without the smallness assumption on \( \|\psi\|_{M^{4,m-2}} \), however since it requires more involved techniques and the result does not directly benefit us in this paper, we postpone the details to a later work.

Layout of the paper. In section 2 we improve the regularity for suitably generalised elliptic systems appearing in [42] - Theorem 2.1 - following the ideas developed in [36, 35]. We also state consequences of this theorem for homogeneous Dirichlet and Neumann boundary value problems for the same system - Theorem 2.7, in order to prove Theorem 1.2. In section 3 we recall the set-up for Dirac-harmonic maps and the related free boundary problem developed in [7]. Section 4 contains the proofs of all of the Theorems concerning Dirac-harmonic maps mentioned in the introduction. In the same section we consider interior and boundary regularity for systems of spinors solving a Dirac equation, where the boundary value problem is of chirality-type - Theorems 4.1 and 4.8. In the appendix we give a brief overview of the classical function spaces we require, along with results on Hodge decompositions, the Coulomb gauge construction of Riviè re-Struwe [30] and some classical boundary value problem estimates for the Laplace and Cauchy-Riemann operator.

2 Supporting PDE results

The first main PDE theorem in this section - Theorem 2.1, is an improved interior regularity result for a system of critical PDE. Systems of this form were introduced and first studied by Riviè re-Struwe [30], however in the present form the improved regularity results, and generalisations thereof stem from works of the authors [42] and [36]. The proof of Theorem 2.1 follows precisely the lines set out in [30] and [42] in obtaining Hölder regularity and we follow [36] in proving the higher integrability. We provide a sketch of the proof of this theorem for the sake of clarity, referring to [36] and [35] for the fine detail.

Theorem 2.1. Let \( m, d \geq 2 \), \( 0 < \Lambda < \infty \) and \( \frac{m}{2} < p < m \). For any \( F, G \in L^\infty \cap M^{2,m-2}_1(B_1, gl(d)), \ A \in L^\infty \cap M^{2,m-2}_1(B_1, GL(d)), \ \Omega \in M^{2,m-2}_1(B_1, so(d) \otimes \wedge^1 \mathbb{R}^m), \ \zeta \in M^{2,m-2}_1(B_1, gl(d) \otimes \wedge^2 \mathbb{R}^m), \ f \in L^p(B_1, \mathbb{R}^d) \) and for any \( u \in M^{2,m-2}_1(B_1, \mathbb{R}^d) \) weakly solving

\[
d^*(\text{Ad}u) = (\Omega, \text{Ad}u) + \langle F d^* \zeta, G d u \rangle + f
\]

with

\[
\Lambda^{-1} |\xi| \leq |A(x)\xi| \leq \Lambda |\xi| \quad \text{for a.e. } x \in B_1, \text{ for all } \xi \in \mathbb{R}^d
\]

and

\[
\|F\|_{L^\infty(B_1)} + \|G\|_{L^\infty(B_1)} + \|\nabla F\|_{M^{2,m-2}(B_1)} + \|\nabla G\|_{M^{2,m-2}(B_1)} \leq \Lambda,
\]

and
there exist \( \epsilon = \epsilon(m, d, \Lambda, p) > 0 \) and \( C = C(m, d, \Lambda, p) > 0 \) such that whenever

\[
\|\Omega\|_{M^{2, m-2}(B_1)} + \|\nabla \zeta\|_{M^{2, m-2}(B_1)} + \|\nabla A\|_{M^{2, m-2}(B_1)} \leq \epsilon
\]

then

\[
\|\nabla^2 u\|_{M^{2, m-2}(B_{\frac{1}{2}})} + \|\nabla u\|_{M^{2, m-2}(B_{\frac{1}{2}})} \leq C(\|u\|_{L^1(B_1)} + \|f\|_{L^p(B_1)}).
\]

**Remark 2.2.** Under the conditions of Theorem 2.1, if \( \zeta \equiv 0 \) and \( f \in L^r \) for all \( r < m \), then we have that for all \( 2 < q < \infty \) there exist \( \epsilon = \epsilon(m, d, \Lambda, q) > 0 \) and \( C = C(m, d, \Lambda, q) > 0 \) such that whenever

\[
\|\Omega\|_{M^{2, m-2}(B_1)} + \|\nabla A\|_{M^{2, m-2}(B_1)} \leq \epsilon
\]

then

\[
\|\nabla^2 u\|_{M^{2, m-2}(B_{\frac{1}{2}})} + \|\nabla u\|_{M^{2, m-2}(B_{\frac{1}{2}})} \leq C(\|u\|_{L^1(B_1)} + \|f\|_{L^p(B_1)}).
\]

To see this notice that

\[
p := \frac{mq}{2 + q} \in \left( \frac{m}{2}, m \right)
\]

and apply the theorem for \( p = p(q) \) where

\[
q = \frac{2p}{p - m}.
\]

**Remark 2.3.** Note that we could have written the PDE as

\[
d^*(Adu) = (\tilde{\Omega}, Adu) + f
\]

where \( \tilde{\Omega} = \Omega + Fd^*\zeta GA^{-1} \) is not antisymmetric. Thus it is clear that in order to have the improved regularity “it is only necessary for the part of \( \Omega \) that has divergence to be anti-symmetric” as has been noted previously: [42] and [33]. We also point out that there have been further generalisations of this type of theorem in different directions - the interested reader should consult the works of Roger Moser [25] and Armin Schikorra [34].

In order to prove Theorem 2.1 we first require a small generalisation of a result of Rivière-Struwe [30] concerning the Hölder regularity of such weak solutions:

**Theorem 2.4 ([30, 31, 42, 33]).** Let the set-up be as in Theorem 2.1 then there exist \( \epsilon = \epsilon(m, n, \Lambda, p) > 0 \) and \( C = C(m, n, \Lambda, p) > 0 \) such that whenever

\[
\|\Omega\|_{M^{2, m-2}(B_1)} + \|\nabla \zeta\|_{M^{2, m-2}(B_1)} + \|\nabla A\|_{M^{2, m-2}(B_1)} \leq \epsilon
\]

then \( u \in C^{0, \gamma}_{\text{loc}} \), for \( \gamma = 2 - \frac{m}{p} \) with

\[
[u]_{C^{0, \gamma}(B_{\frac{1}{2}})} \leq C(\|\nabla u\|_{M^{2, m-2}(B_1)} + \|f\|_{L^p(B_1)}).
\]

**Remark 2.5.** We point out here that both Theorem 2.1 and Theorem 2.4 remain true if we consider the domain to be equipped with a Lipschitz Riemannian metric \( (B_1, g_1) \) where \( g_1 \) is arbitrary. Of course in this case \( d^*_g \) would depend on \( g_1 \) as would the inner product \( \langle \cdot, \cdot \rangle_{g_1} \). We will not give a proof of this fact here as the proof follows the same lines as the Euclidean setting with some added technicalities.

**Remark 2.6.** The conclusion of Theorem 2.1 is stronger than that of Theorem 2.4 since we have (see [12, Chapter III, Theorem 1.2])

\[
[u]_{C^{0, \gamma}} \leq C\|\nabla u\|_{M^{2, m-2}}.
\]
Our second main PDE result in this section is to present estimates up to the boundary when we have zero Dirichlet and/or Neumann conditions. Denote by $B^+_1 := B_1 \cap \{ x_m \geq 0 \}$ the upper half unit ball and set $I := \{(x_1, ..., x_{m-1}, 0) \in \mathbb{R}^m | -1 < x_1, ..., x_{m-1} < 1 \}.$

**Theorem 2.7.** Let $m,d \geq 2, 0 \leq s \leq d, 0 < \Lambda \ll \infty$ and $\frac{m}{2} < p < m.$ For any $A \in L^\infty \cap M^{2,m-2}(B^+_1, \text{GL}(d)), \Omega \in M^{2,m-2}(B^+_1, \text{so}(d) \otimes \Lambda^1 \mathbb{R}^m),$ $f \in L^p(B^+_1, \mathbb{R}^d)$ and for any $u \in M^{2,m-2}(B^+_1, \mathbb{R}^d)$ weakly solving
\[
\begin{align*}
&d^*(Adu) = \langle \Omega, Adu \rangle + f \quad \text{in } B^+_1, \\
&\frac{\partial u^i}{\partial n} = 0 \quad \text{on } I \quad 1 \leq i \leq s, \\
&u^j = 0 \quad \text{on } I \quad s + 1 \leq j \leq d,
\end{align*}
\]  
with 
\[
\Lambda^{-1} |\xi| \leq |A(x)\xi| \leq \Lambda |\xi| \quad \text{for a.e. } x \in B^+_1, \quad \text{for all } \xi \in \mathbb{R}^d
\]
and satisfying the compatibility condition that $A(x)$ commutes with $R$ for almost every $x \in B^+_1$ where $R$ is as in (1.6), there exist $\epsilon = \epsilon(m,d,\Lambda,p) > 0$ and $C = C(m,d,\Lambda,p) > 0$ such that whenever
\[
\|\Omega\|_{M^{2,m-2}(B^+_1)} + \|\nabla A\|_{M^{2,m-2}(B^+_1)} \leq \epsilon
\]
then 
\[
\|\nabla^2 u\|_{M^{2,m-2}(B^+_2)} + \|\nabla u\|_{M^{2,m-2}(B^+_2)} \leq C(\|u\|_{L^1(B^+_1)} + \|f\|_{L^p(B^+_1)}).
\]

**Remark 2.8.** As above we can make sense of this theorem when $B^+_1$ is equipped with a Riemannian metric $g^+_1,$ but we require that it is in block form:
\[
g^+_1 = \begin{pmatrix}
(g_{ij})_{ij}^+ & 0 \\
0 & 0
\end{pmatrix}
\]
The reader should think of this condition as taking local Fermi coordinates with respect to $\partial M \subset M$ about some boundary point $p$ which we can always do, i.e., about $p \in \partial M$ we can find a chart $\phi : U \subset M \to B^+_1$ such that $\phi(U \cap \partial M) = I$ and the metric is in the form above.

In dimension $m = 2,$ we are able to deal with the case of inhomogeneous Neumann and Dirichlet boundary constraints - our main PDE result in the paper Theorem 1.2. Here, we point out the following Corollary of Theorem 1.2 to the reader, the proof of which is left as an exercise:

**Corollary 2.9.** Let $U \subset \mathbb{R}^2$ be an open domain and $T \subset U$ a smooth boundary portion. Let $d \geq 2,$ $0 \leq s \leq d, 0 < \Lambda \ll \infty$ and $1 < p < 2.$ For any $A \in L^\infty \cap W^{1,2}(U, GL(d)), \Omega \in L^2(U, \text{so}(d) \otimes \Lambda^1 \mathbb{R}^2),$ $f \in L^p(U, \mathbb{R}^d), (g, \xi) \in (W^{1,p}_0(T, \mathbb{R}^d), W^{2,p}_0(T, \mathbb{R}^{d-s}))$ and for any $u \in W^{1,2}(U, \mathbb{R}^d)$ weakly solving
\[
\begin{align*}
&d^*(Adu) = \langle \Omega, Adu \rangle + f \quad \text{in } U, \\
&\frac{\partial u^i}{\partial n} = g^i \quad \text{on } T \quad 1 \leq i \leq s, \\
&u^j = \xi^j \quad \text{on } T \quad s + 1 \leq j \leq d,
\end{align*}
\]  
with 
\[
\Lambda^{-1} |\xi| \leq |A(x)\xi| \leq \Lambda |\xi| \quad \text{for a.e. } x \in U, \quad \text{for all } \xi \in \mathbb{R}^d
\]
and satisfying the compatibility condition that $A(x)$ commutes with $R$ for almost every $x \in U,$ where $R$ is as in (1.6), then we have $u \in W^{2,p}_0(U \cup T)$ and for any $V \subset U \cup T,$ there exist $\epsilon = \epsilon(d, \Lambda, p, V) > 0$ and $C = C(d, \Lambda, p, V) > 0$ such that whenever
\[
\|\Omega\|_{L^2(U)} + \|\nabla A\|_{L^2(U)} \leq \epsilon
\]
then 
\[
\|\nabla^2 u\|_{L^p(V)} + \|\nabla u\|_{L^{2p}_0(V)} \leq C(\|u\|_{L^1(U)} + \|f\|_{L^p(U)} + \|g\|_{W^{1,p}_0(T)} + \|\xi\|_{W^{2,p}_0(T)}).
\]
Remark 2.10. In particular if \( U \) is any smooth domain then we can apply the above theorem for \( T = \partial U \) and \( V = \bar{U} \).

2.1 Proof of Theorems 2.7 and 1.2

Proof of Theorem 2.7: First we define reflections in the domain and target: In the domain we denote \( \rho : \mathbb{R}^m \to \mathbb{R}^m \) to be \( \rho(x) := (\rho_1(x), \ldots, \rho_m(x), -x_m) \) and in the target, \( \sigma : \mathbb{R}^d \to \mathbb{R}^d \) defined by \( \sigma(y) = (y^1, \ldots, y^s, -y^{s+1}, \ldots, -y^d) \) - note that \( R \) is the matrix describing both \( \sigma \) and \( D\sigma \). Now we extend the objects appearing in the Theorem as follows:

\[
\begin{align*}
\hat{u}_E(x) := & \begin{cases} 
  u(x) & \text{if } x \in B_1^+ \\
  Ru(\rho(x)) & \text{if } x \in B_1^- 
\end{cases} \in W^{1,2}(B_1, \mathbb{R}^d), \\
\hat{A}_E(x) := & \begin{cases} 
  A(x) & \text{if } x \in B_1^+ \\
  A(\rho(x)) & \text{if } x \in B_1^- 
\end{cases} \in W^{1,2}(B_1, GL(d)), \\
\hat{\Omega}_E(x) := & \begin{cases} 
  \Omega(x) & \text{if } x \in B_1^+ \\
  R(\rho^*\Omega)(x)R & \text{if } x \in B_1^- 
\end{cases} \in L^2(B_1, so(d) \otimes \Lambda^1 \mathbb{R}^m), \\
\hat{f}_E(x) := & \begin{cases} 
  f(x) & \text{if } x \in B_1^+ \\
  Rf(\rho(x)) & \text{if } x \in B_1^- 
\end{cases} \in L^p(B_1, \mathbb{R}^d).
\end{align*}
\]

Now, for any \( \eta \in C^\infty_0(B_1, \mathbb{R}^d) \) we decompose it as follows

\[
\eta(x) = \eta_1(x) + \eta_2(x) = \frac{1}{2}(\eta(x) + R\eta(\rho(x))) + \frac{1}{2}(\eta(x) - R\eta(\rho(x)))
\]

where we have \( R\eta_1(\rho(x)) = \eta_1(x) \) \( R\eta_2(\rho(x)) = -\eta_2(x) \).

As a preliminary calculation we check that

\[
\int_{B_1^+} \langle \hat{\Omega}(x), A(x)du(x) \rangle + f(x), \eta_1(x) \rangle = \int_{B_1^-} \langle (\rho^*\hat{\Omega})(x), A(\rho(x))du(\rho(x)) + f(\rho(x)), \eta_1(\rho(x)) \rangle \\
= \int_{B_1^-} \langle \hat{\Omega}(x), A(\rho(x))du(\rho(x)) + f(\rho(x)), \eta_1(\rho(x)) \rangle \\
= \int_{B_1^-} \langle \Omega_E(x), A_E(x)du_E(x) \rangle + f_E(x), \eta_1(x) \rangle.
\]

Therefore by (2.1) and the fact that \( \eta_j^i = 0 \) on \( I \) for \( s + 1 \leq j \leq d \) we have

\[
\int_{B_1} \langle A_Edu_E, d\eta_1 \rangle = \int_{B_1^+} (Adu, d\eta_1) + \int_{B_1^-} (A(\rho(x))Rdu(\rho(x)), d\eta_1(x)) \\
= \int_{B_1^+} \langle \Omega, Adu \rangle + f, \eta_1 \rangle + \int_{B_1^-} \langle A(\rho(x))Rdu(\rho(x)), Rd(\eta_1), \rho(\rho(x)) \rangle \\
= \int_{B_1^+} \langle \Omega, Adu \rangle + f, \eta_1 \rangle + \int_{B_1^-} \langle A(du(\rho(x)), d\eta_1(x)) \rangle \\
= 2 \int_{B_1^+} \langle \Omega, Adu \rangle + f, \eta_1 \rangle \\
= \int_{B_1} \langle \Omega_E(x), A_E(x)du_E(x) \rangle + f_E(x), \eta_1(x) \rangle.
\]

9
We also check that
\[
\int_{B_1^+} (A_E du_E, d\eta_2)^+ = \int_{B_1^+} (A du, d\eta_2) + \int_{B_1^+} (A(\rho(x)) Rd(u \circ \rho)(x), d\eta_2(x)) \\
= \int_{B_1^+} (A du, d\eta_2) - \int_{B_1^+} (A(\rho(x)) Rd(u \circ \rho)(x), Rd(\eta_2 \circ \rho)(x)) \\
= \int_{B_1^+} (A du, d\eta_2) - \int_{B_1^+} (A(x) du(x), d\eta_2(x)) \\
= 0.
\]

On the other hand, a simple calculation gives
\[
\int_{B_1^+} ((\Omega(x), A(x) du(x)) + f(x), \eta_2(x)) = \int_{B_1^+} ((\rho^* \Omega(x), A(\rho(x)) d(u \circ \rho)(x)) + f(\rho(x)), \eta_2(\rho(x))) \\
= - \int_{B_1^+} ((\rho^* \Omega(x), A(\rho(x)) d(u \circ \rho)(x)) + f(\rho(x)), R\eta_2(x)) \\
= - \int_{B_1^+} ((\Omega_E(x), A_E(x) du_E(x)) + f_E(x), \eta_2(x)).
\]

It follows that
\[
\int_{B_1} ((\Omega_E(x), A_E(x) du_E(x)) + f_E(x), \eta_2(x)) = 0.
\]

Therefore we have proved that for all such \( \eta \) we have
\[
\int_{B_1} (A_E du_E, d\eta) = \int_{B_1} ((\Omega_E(x), A_E(x) du_E(x)) + f_E(x), \eta(x)).
\]

By applying Theorem 2.1 we are done. \( \Box \)

Before we begin the proof of Theorem 1.2 we first recall a fundamental result of Agmon-Douglis-Nirenberg [2], the proof of which we leave to the reader - see [40, Theorem 3.4].

**Theorem 2.11.** Let \( G \in W^{1,p}(B_1^+) \) for \( 1 < p < \infty \). Then there exist \( C = C(p) > 0 \) and \( \hat{u}_G \in W^{2,p}(B_1^+) \) such that
\[
\frac{\partial \hat{u}_G}{\partial \bar{n}} = G|_I \quad \text{and} \quad \|\hat{u}_G\|_{W^{2,p}} \leq C\|G\|_{W^{1,p}}.
\]

**Proof of Theorem 1.2:** By the definition of the spaces \( W^{k,p}_\partial \) and the above theorem we can find \( \hat{u} \in W^{2,p}(B_1^+) \) such that
\[
\frac{\partial \hat{u}}{\partial \bar{n}} = g^i \quad \text{on} \quad I \quad 1 \leq i \leq s \\
\hat{u}^j = t^j \quad \text{on} \quad I \quad s + 1 \leq j \leq d,
\]
and \( C = C(p) > 0 \) with
\[
\|\hat{u}\|_{W^{2,p}} \leq C(\|g\|_{W^{1,p}} + \|t\|_{W^{2,p}}).
\]

Defining \( v := u - \hat{u} \) and \( F := f - d^*(Ad\hat{u}) + \langle \Omega, Ad\hat{u} \rangle \), the reader can check that we have
\[
d^*(Adv) = \langle \Omega, Adv \rangle + F \quad \text{on} \quad B_1^+
\]
with \( v \) satisfying the boundary conditions (2.1) and
\[
\|F\|_{L^p(B_1^+)} \leq C(\|f\|_{L^p(B_1^+)} + \|g\|_{W^{1,p}} + \|t\|_{W^{2,p}}).
\]
Now we apply Theorem 2.7 to \( v \) for \( m = 2 \) which eventually gives the desired estimate for \( u \). \( \square \)
2.2 Proof of Theorems 2.4 and 2.1

Proof of Theorem 2.4: The proof we give follows the ideas set out in [30, 31], see also [33, 42]. Setting $T := P^{-1}A$ where $P$ is given by the Morrey version of the Coulomb gauge, Theorem D.1, we end up with the system

$$d^*(Tdu) = \langle d^*\xi, Tdu \rangle + \langle P^{-1}F d^*\zeta, GAdu \rangle + P^{-1}f$$

and

$$d(Tdu) = dT \wedge du.$$ 

Note that

$$\|T\|_{L^\infty} \leq \Lambda,$$

and

$$\frac{1}{\Lambda} |du| \leq |Tdu| \leq \Lambda |du|.$$

and

$$\|\nabla T\|_{M^{2,m-2}(B_1)} \leq C\epsilon.$$

Pick $t = t(m, p)$ such that $1 < t < \frac{m+n}{m}$ and $t\gamma < 1$ where $\gamma = 2 - \frac{mp}{p} \in (0, 1)$. We can perform a Hodge decomposition (see appendix C)

$$Tdu = da + d^*b + h$$

for $a \in W^{1,t}_0(B_1, \mathbb{R}^d)$, $b \in W^{1,\gamma}_N(B_1, \mathbb{R}^d \otimes \Lambda^2 \mathbb{R}^m)$ and $h \in L^t(B_1, \mathbb{R}^d \otimes \Lambda^1 \mathbb{R}^m)$ is harmonic ($dh = d^*h = 0$). We obtain the following bounds by the usual duality arguments:

$$\|da^t\|_{L^t(B_1)} \leq C(t) \sup_{\phi \in C^\infty_0(B_1)} \|\nabla \phi\|_{L^{t^*}(B_1)} (da^t, d\phi) \quad (2.3)$$

and

$$\|d^*b\|_{L^t(B_1)} \leq C(t) \sup_{\phi \in C^\infty_0(B_1, \Lambda^2 \mathbb{R}^m)} \|\nabla \phi\|_{L^{t^*}(B_1)} (d^*b, d^*\phi). \quad (2.4)$$

Before we begin to estimate these quantities we first need to extend some of the objects arising above. By standard extension arguments we consider $\tilde{T}, \tilde{P}, \tilde{F}, \tilde{G}$ each considered as a function on $\mathbb{R}^m$ with $\tilde{\cdot} = \cdot$ in $B_1$ and

$$\|\tilde{T}\|_{W^{1,2}} + \|\tilde{T}\|_{L^\infty} \leq C(\|\cdot\|_{W^{1,2}(B_1)} + \|\cdot\|_{L^\infty(B_1)}).$$

We extend $u$ to $\bar{u}$, defined on $\mathbb{R}^m$ (see appendix A) with

$$[\bar{u}]_{BMO} \leq C[u]_{BMO(B_1)}$$

and we define $\bar{\zeta}$ and $\tilde{T}$ by extending $(\zeta - \zeta_1, \bar{\zeta})$ and $(T - T_1, \bar{T})$ in $W^{1,2}$ respectively (where $g_{r,x} = \bar{f}_{B_r(x)} g$). Hence $\nabla \bar{\zeta} = \nabla \tilde{\zeta}, \nabla T = \nabla \tilde{T}$ in $B_1$ and

$$\|\nabla \tilde{\zeta}\|_{L^2} + \|\nabla \tilde{T}\|_{L^2} \leq C\epsilon.$$

We also extend any such $\phi$ and $\eta$ by zero and we can extend any $\psi$ to a two-form $\tilde{\psi} \in C^\infty_0(B_2, \Lambda^2 \mathbb{R}^m)$ and

$$\|\nabla \tilde{\psi}\|_{L^{t^*}} \leq C.$$
Now we can check

\[
(d^a \iota, \phi) = (d^*(Tdu)^i, \phi) \\
= (d^*\eta_i, Td\eta)^i + (P^{-1}F d^*\zeta, G A du)^i + \int_{B_1} (P^{-1}f)^i \phi \\
= (d^*\eta_i, d(Tr\phi))^i - [(d^*\eta_i, d(T\phi))u]^i + (d^*\zeta^h_i, d[(P^{-1})^j F^k_i G^l A^m_k u^h \phi]) \\
\phantom{= (d^*\eta_i, d(Tr\phi))^i} - (d^*\zeta^h_i, d[(P^{-1})^j F^k_i G^l A^m_k u^h \phi])u^h + \int_{B_1} (P^{-1}f)^i \phi \\
= -[(d^*\eta_i, d(Tr\phi))\bar{u}]^i + (d^*\zeta^h_i, d[(P^{-1})^j F^k_i G^l A^m_k \phi])\bar{u}^h \\
\phantom{= (d^*\eta_i, d(Tr\phi))^i} + \int_{B_1} (P^{-1}f)^i \phi \text{ because of the boundary values (see appendix C)} \\
\leq C((\|\nabla \phi\|_{L^2} + \|\phi\|_{L^\infty})c[BMO(B_1)] + ||\phi||_{L^\infty} ||f||_{L^1}) \\
\leq C(c[BMO(B_1)] + ||f||_{L^p(B_1)}) \quad (2.5)
\]

where we have used the Hardy-BMO duality [10] and results of Coifman et.al [8] (see appendix A). Putting together (2.3) and (2.5) we have

\[
||d^a||_{L^1(B_1)} \leq C(c[BMO(B_1)] + ||f||_{L^p(B_1)}). \quad (2.6)
\]

Using (2.4) and similar methods as above we can check that

\[
||d^b||_{L^1(B_1)} \leq C(t) \sup_{\psi \in C^{\infty}_c(B_1, \mathbb{R}^{2m})} (d^*b, d^*\psi) \\
= C \sup_{\psi \in C^{\infty}_c(B_1, \mathbb{R}^{2m}), \|\nabla \psi\|_{L^1(B_1)} \leq 1} (dT \wedge du, \psi) \\
= C \sup_{\psi \in C^{\infty}_c(B_1, \mathbb{R}^{2m}), \|\nabla \psi\|_{L^1(B_1)} \leq 1} \int_{B_1} (dT \wedge du) \wedge *\psi \\
\leq C \sup_{\psi \in C^{\infty}_c(B_1, \mathbb{R}^{2m}), \|\nabla \psi\|_{L^1(B_1)} \leq 1} \int_{B_1} (dT \wedge du) \wedge *\tilde{\psi} \\
\leq C \sup_{\psi \in C^{\infty}_c(B_2, \mathbb{R}^{2m}), \|\nabla \psi\|_{L^1(B_1)} \leq 1} (d\tilde{T}, d^*\tilde{\psi}) \tilde{\psi} \\
\leq C(\psi)[BMO(B_1)]. \quad (2.7)
\]

Now, by standard properties of harmonic functions (see [18, Lemma 3.3.12]) we know that

\[
||h||_{L^1(B_1)} \leq r^m ||h||_{L^1(B_1)} \leq Cr^{-m} ||Tdu||_{L^1(B_1)}
\]

We can estimate

\[
||Tdu||_{L^1(B_1)} \leq C(||d^a||_{L^1(B_1)} + ||d^b||_{L^1(B_1)} + ||h||_{L^1(B_1)}).
\]

Thus we are left with (using (2.6) and (2.7))

\[
||Tdu||_{L^1(B_1)} \leq C(c[BMO(B_1)] + ||f||_{L^p(B_1)} + r^{-m} ||Tdu||_{L^1(B_1)}).
\]

Hence by a scaling argument

\[
\frac{||Tdu||_{L^1(B_1, x_0)}}{(rR)^{m-t}} \leq C \left( \frac{c[BMO(B_1, x_0)]}{r^{m-t}} + R^{(2 - \frac{p}{q})} \frac{||f||_{L^p(B_1, x_0)}}{r^{m-t}} + \frac{||Tdu||_{L^1(B_1, x_0)}}{r^{-t}R^{m-t}} \right)
\]

12
for any $B_R(x_0) \subset B_1$, where we have also multiplied by $r^{t-m}$. As in [31, 30, 33] we define
\[
\Phi(x_0, \rho) := \rho^{t-m} \| T \omega \|_{L^t(B_{\rho}(x_0))}
\]
and
\[
\Psi(\bar{\rho}) = \sup_{x_0 \in B_{\frac{1}{2}} \setminus 0 < \rho < \frac{1}{2}} \Phi(x_0, \rho).
\]
By Poincaré’s inequality and the properties of $T$ we have
\[
\sup_{x_0 \in B_{\frac{1}{2}} \setminus 0 < \rho < \frac{1}{2}} [u]^t_{BMQ(B_0(x_0))} \leq C\Psi(\bar{\rho}).
\]
Thus we have
\[
\Psi(rR) \leq C(\epsilon^t r^{t-m} + r^t)\Psi(R) + CR\gamma r^{t-m} \| f \|_{L^p(B_1)}^t.
\]
Now fix $r$ sufficiently small such that $C\gamma \frac{1}{r} \leq \frac{1}{2}$ and subsequently $\epsilon$ sufficiently small such that $\epsilon^t \leq r^m$, giving us
\[
\Psi(rR) \leq r^{\frac{t-m}{2}}\Psi(R) + CR\gamma \| f \|_{L^p(B_1)}^t.
\]
Given $s \in (0, r]$ we have $r^{t+1} < s \leq r^l$ for some $l \in \mathbb{N}$. Thus
\[
\Psi(s) \leq \Psi(r^l) \leq r^{\frac{t-m}{2}}\Psi(r^{l-1}) + r^{(l-1)t\gamma}C\| f \|_{L^p(B_1)}^t
\]
and iterating this we get
\[
\Psi(s) \leq C(r^{(l+1)t\gamma} - t^m) \Psi(r) + \sum_{j=0}^{\infty} r^j \| f \|_{L^p(B_1)}^t \| \nabla u \|_{M^{2, m-2}(B_{\frac{1}{2}})} + \| f \|_{L^p(B_1)}^t
\]
where we have used that $t\gamma < 1 < \frac{t-m}{2}$. Thus we have the estimate
\[
\| \nabla u \|_{M^{1, m-2+t\gamma}(B_{\frac{1}{2}})} \leq C(\| \nabla u \|_{M^{2, m-2}(B_1)} + \| f \|_{L^p(B_1)})
\]
and standard Morrey growth estimates (see [12, Chapter III]) give
\[
[u]_{C^\gamma(B_{\frac{1}{2}})} \leq C\| \nabla u \|_{M^{1, m-2+t\gamma}(B_{\frac{1}{2}})}.
\]
\[
\square
\]
**Proof of Theorem 2.1:** We first assume the following:

**Proposition 2.12.** Let the setup be as in Theorem 2.1. Then there exits $\epsilon = \epsilon(d, m, p, \Lambda) > 0$ such that whenever
\[
\| \Omega \|_{M^{2, m-2}(B_1)} + \| \nabla \zeta \|_{M^{2, m-2}(B_1)} + \| \nabla A \|_{M^{2, m-2}(B_1)} \leq \epsilon
\]
then $\nabla u \in M^2_{2, m-2+2\gamma}(B_1, \mathbb{R}^d)$.

We now follow precisely the bootstrapping argument of [36] (see also [35, Chapter 6]) therefore we do the first few lines and then refer the reader there for the full proof. Setting $\Theta := A^{-1}dA + A^{-1}\Omega A + A^{-1}Fd^* \zeta G \in M^{2, m-2}(B_1, g(d) \otimes \mathbb{1} \mathbb{R}^m)$ we have that
\[
\| \Theta \|_{M^{2, m-2}(B_1)} \leq C(\Lambda)\epsilon
\]
and \( u \) is a solution to:
\[
-\Delta u = (\Theta, d u) + f.
\]
Using the fact that now we know \( \nabla u \) has better than \( L^2 \) integrability we can simply bootstrap this information back into our PDE. This completes the proof of Theorem 2.1. \( \square \)

**Proof of Proposition 2.12:** We can of course apply Theorem 2.4 to our situation in Theorem 2.1. Now we assume the following:

**Proposition 2.13.** With the set-up as in Theorem 2.1; let \( \delta > 0 \), then there exist \( \epsilon = \epsilon(d, m, p, \Lambda) > 0 \) small enough and \( C = C(\delta, m, d, p, \Lambda) > 0 \) such that when
\[
\| \Omega \|_{M^{2,m-2}(B_1)} + \| \nabla \zeta \|_{M^{2,m-2}(B_1)} + \| \nabla A \|_{M^{2,m-2}(B_1)} \leq \epsilon
\]
we have the following estimate (\( \gamma = 2 - \frac{m}{p} \))
\[
\| A \nabla u \|_{L^2(B_1)}^2 \leq C(\delta)(\epsilon^2 \| u \|_{W^{1,\gamma}(B_1)}^2 + \| f \|_{L^p(B_1)}^2) + \gamma m(1 + \delta)\| A \nabla u \|_{L^2(B_1)}^2.
\]

Assuming Proposition 2.13 we follow the argument for the proof of [37, Lemma 7.3], again the full details are given in [36] or [35, Chapter 6], however one should follow the argument by replacing \( \nabla u \) with \( A \nabla u \). This finishes the proof of Proposition 2.12. \( \square \)

**Proof of Proposition 2.13:** This section of the proof also follows exactly the ideas set out in [36] and [35, Chapter 6] but we include some of the details since there are a couple of added technicalities here: We will use the Coulomb gauge in order to re-write our equation, so set \( \epsilon \) small enough so that we can apply Theorem D.1. We have
\[
d^*(P^{-1}A d u) = \langle d^* \eta, P^{-1}A d u \rangle + \langle P^{-1}F d^* \zeta, G d u \rangle + P^{-1}f
\]
and
\[
d(P^{-1}A d u) = (d(P^{-1}A) \wedge d u).
\]
Letting \( S = P^{-1}A \) we have
\[
d^*(S d u) = \langle d^* \eta, S d u \rangle + \langle P^{-1}F d^* \zeta, G d u \rangle + P^{-1}f
\]
and
\[
d(S d u) = (d S \wedge d u)
\]
where
\[
\frac{1}{\Lambda} |\xi| \leq |S(x)\xi| \leq \Lambda |\xi|
\]
for all \( \xi \in \mathbb{R}^n \) and almost every \( x \in B_1 \). We also have
\[
\| \nabla S \|_{M^{2,m-2}(B_1)} \leq \epsilon(\Lambda + 1).
\]
We can also set \( \epsilon \) small enough in order to apply Theorem 2.4 so that \( u \in C^{0,\gamma} \) where \( \gamma = 2 - \frac{m}{p} \in (0,1) \). Now we wish to extend the quantities arising above in the appropriate way: First of all we may extend \( \eta \) by zero. We also extend \( S - S_{1,2} \) to \( \tilde{S} \in W^{1,2} \cap L^\infty(\mathbb{R}^m) \) and finally \( u \) to \( \tilde{u} \in C^{0,\gamma}(\mathbb{R}^m) \) where each has compact support in \( B_2 \) (we may assume \( u \in C^{0,\gamma}(\overline{B_1}) \)).

Note that we have \( \| \nabla \tilde{S} \|_{L^2} \leq C \| \nabla S \|_{L^2(B_1)} \leq C \epsilon(\Lambda + 1) \) by Poincaré’s inequality and \( \nabla \tilde{S} = \nabla S \) in \( B_1 \). We also have \( \tilde{u} \in C^{0,\gamma}(\mathbb{R}^m) \) with \( \| \tilde{u} \|_{C^{0,\gamma}} \leq C \| u \|_{C^{0,\gamma}} \) and (since we may assume \( \int u = 0 \)) we have \( \| \tilde{u} \|_{C^{0,\gamma}} \leq C \| u \|_{C^{0,\gamma}} \). Moreover \( \tilde{u} = u \) in \( B_1 \). All the constants here come from standard extension operators and are independent of the function, see for instance [13]. We also extend \( \zeta - \zeta_{1,2} \) to \( \tilde{\zeta} \in M^{2,m-2}(\mathbb{R}^m) \) with \( \nabla \tilde{\zeta} = \nabla \zeta \) in \( B_1 \) and
\[
\| \nabla \tilde{\zeta} \|_{M^{2,m-2}} \leq C \| \nabla \zeta \|_{M^{2,m-2}(B_1)} \leq C \epsilon.
\]
(see appendix B). We also extend $P, F, G$ using appendix B.

Now we use the $L^2$ version of Theorem C.1 in order to write

$$Sd u = da + d^* b + h$$

with $a, b, h$ as in the Theorem. Notice that we have

$$\Delta a = (d^* \eta, Sd u) + (P^{-1} F d^* \zeta, Gd u) + P^{-1} f$$

and $\Delta b = dS \wedge d u$ weakly. We proceed to estimate $S \nabla u \in L^2$ by estimating $\|d a\|_{L^2}, \|d^* b\|_{L^2}$ and using standard properties of harmonic functions in order to deal with $\|h\|_{L^2}$. The next part of the proof follows from [36] or [35, Chapter 6] with a few extra terms involving our extensions above, however we still obtain:

$$\|\nabla a\|_{L^2(B_i)} \leq C(\epsilon[u]_{C^{0,\gamma}(B_i)} + \|f\|_{L^p(B_i)}). \quad (2.8)$$

and

$$\|d^* b\|_{L^2(B_i)} \leq C\epsilon[u]_{C^{0,\gamma}(B_i)}. \quad (2.9)$$

We now use the fact that $h$ is harmonic giving that the quantity $r^{-m} \|h\|_{L^2(B_i)}^2$ is increasing, and Theorem C.1 to give

$$\|h\|_{L^2(B_i)}^2 \leq r^m \|h\|_{L^2(B_i)}^2 \leq r^m \|Sd u\|_{L^2(B_i)}^2 = r^m \|A d u\|_{L^2(B_i)}^2$$

where the last line follows because $P$ is orthogonal.

Going back to our original Hodge decomposition we see that (using Young’s inequality, the orthogonality of $P$, (2.8) and (2.9))

$$\|A d u\|_{L^2(B_i)}^2 = \|Sd u\|_{L^2(B_i)}^2 \leq (\|h\|_{L^2(B_i)}^2 + \|d a\|_{L^2(B_i)}^2 + \|d^* b\|_{L^2(B_i)}^2)^2 \leq (1 + \delta)\|h\|_{L^2(B_i)}^2 + C(\delta)(\|d a\|_{L^2(B_i)}^2 + \|d^* b\|_{L^2(B_i)}^2)^2 \leq (1 + \delta) r^m \|A d u\|_{L^2(B_i)}^2 + C(\delta)(\epsilon^2[u]_{C^{0,\gamma}(B_i)} + \|f\|_{L^p(B_i)}^2).$$

This completes the proof. \hfill $\square$

### 3 Overview of Dirac-harmonic maps and the free boundary value problem

#### 3.1 Dirac-harmonic maps

In this subsection, we shall recall the geometric set up of Dirac-harmonic maps [5, 6, 41, 7, 39] in general dimensions $m \geq 2$.

Let $(M, g_M)$ be a Riemannian manifold of dimension $m \geq 2$ and with a fixed spin structure. Let $\Sigma M$ be the spinor bundle over $M$ with a hermitian metric $(\cdot, \cdot)_{\Sigma M}$ and a compatible spin connection $\nabla$. For $X \in \Gamma(TM)$ and $\psi \in \Gamma(\Sigma M)$, denote by $X \cdot \psi$ the Clifford multiplication, satisfying:

$$\langle X \cdot \psi, \varphi \rangle = -\langle \psi, X \cdot \varphi \rangle, \quad X \cdot Y \cdot \psi + Y \cdot X \cdot \psi = -2g_M(X, Y)\psi,$$  \quad (3.1)
for any \(X, Y \in \Gamma(TM)\) and any \(\psi, \varphi \in \Gamma(S^1)\). The usual Dirac operator \(\mathcal{D}\) is defined by \(\mathcal{D} \psi := \gamma_\alpha \cdot \nabla_\gamma \psi\) for a local orthonormal frame \(\{\gamma_\alpha\}_{\alpha=1}^n\) on \(M\) and a usual spinor \(\psi \in \Gamma(S^1)\). The summation convention will be used throughout the paper. We refer to [24, 22] for more spin geometric materials.

Let \((N, g)\) be a compact Riemannian manifold of dimension \(d \geq 2\) and let its metric in local coordinates \(\{y^i\}_{i=1}^d\) be given by \(g_{ij}\), with Christoffel symbols \(\Gamma^i_{jk}\) and Riemannian curvature tensor \(R^m_{ijl}\). Let \(\phi\) be a smooth map from \(M\) to \(N\) and \(\phi^{-1}TN\) the pull-back bundle of \(TN\) under \(\phi\). Consider the twisted bundle \(\Sigma M \otimes \phi^{-1}TN\) with the induced metric \((\cdot, \cdot)_{\Sigma M \otimes \phi^{-1}TN}\) and the induced connection \(\nabla := \nabla + 1 \otimes \nabla_{\phi^{-1}TN}\). In local coordinates, the section \(\psi\) of \(\Sigma M \otimes \phi^{-1}TN\) can be expressed by \(\psi(x) = \sum_{j=1}^d \psi^j(x) \otimes \partial_j(\phi(x))\), where \(\psi^j\) is a usual spinor and \(\{\partial_j = \partial y^j\}\) is the natural local basis on \(N\). \(\nabla\) can be expressed by

\[
\nabla \psi = \sum_{i=1}^d \nabla \psi^i(x) \otimes \partial_i(\phi(x)) + \sum_{i,j,k=1}^d \Gamma^i_{jk}(\phi(x)) \psi^i(\gamma_\alpha) \gamma_\alpha \cdot \psi^k(x) \otimes \partial_i(\phi(x)).
\]

The Dirac operator along the map \(\phi\) is defined by

\[
D_{\phi} \psi := \gamma_\alpha \cdot \nabla_\gamma \psi = \sum_i \phi \psi^i(\phi(x)) \otimes \partial_i(\phi(x)) + \sum_{i,j,k=1}^d \Gamma^i_{jk}(\phi(x)) \phi^i(\gamma_\alpha) \gamma_\alpha \cdot \psi^k(x) \otimes \partial_i(\phi(x)).
\]

Set

\[
\mathcal{A}(M, N) := \{ (\phi, \psi) | \phi \in C^\infty(M, N) and \psi \in C^\infty(\Sigma M \otimes \phi^{-1}TN) \}.
\]

Consider the following functional on \(\mathcal{A}(M, N)\):

\[
L(\phi, \psi) := \int_M (\|d\phi\|^2 + \langle \psi, D\psi \rangle) \, dV_{gM}.
\]

In terms of local coordinates, the functional \(L(\cdot, \cdot)\) can be expressed as:

\[
L(\phi, \psi) = \int_M (g_{ij}(\phi) \langle d\phi^i, d\phi^j \rangle_{gM} + g_{ij}(\phi) \langle \psi^i, \psi^j \rangle) \, dV_{gM},
\]

and the corresponding Euler-Lagrange equations are:

\[
-\Delta_{gM} \psi^i + \Gamma^i_{jk}(\phi) \phi^k(\gamma_\alpha) \gamma_\alpha \cdot \psi^j = 0, \quad i = 1, 2, \ldots, d, \quad (3.2)
\]

\[
\phi \psi^i + \Gamma^i_{jk}(\phi) \nabla \phi^j \cdot \psi^k = 0, \quad i = 1, 2, \ldots, d. \quad (3.3)
\]

Here \(\Delta_{gM}\) is the Laplace-Beltrami operator with respect to \(g_M\), \(\nabla \phi^j := \nabla g_{ij} \phi^j = \partial_y^i(\gamma_\alpha) \phi^j = \phi^j_{\alpha} \gamma_\alpha\) and \(“\cdot”\) denotes the Clifford multiplication. Solutions \(\phi, \psi \in \mathcal{A}(M, N)\) to (3.2), (3.3) are called Dirac-harmonic maps from \(M\) to \(N\).

We embed \(N\) isometrically into some Euclidean space \(\mathbb{R}^n\) via the Nash-Moser embedding theorem. Let \(\mathcal{A}(\cdot, \cdot)\) be the second fundamental form of \(N\) in \(\mathbb{R}^n\), and \(P\) the shape operator of \(N\) in \(\mathbb{R}^n\). Set

\[
\mathcal{A}(d\phi(\gamma_\alpha), \gamma_\alpha \cdot \psi) = \phi^j_{\alpha} \gamma_\alpha \cdot \psi^j \otimes \mathcal{A}(\partial_y^j, \partial_y^j),
\]

\[
\mathcal{P}(\mathcal{A}(d\phi(\gamma_\alpha), \gamma_\alpha \cdot \psi) \psi) = P(\mathcal{A}(\partial_y^j, \partial_y^j); \partial_y^j)(\psi^i, \gamma_\alpha \cdot \psi^j \phi^i_{\alpha}).
\]

By the Gauss equation, the equations (3.2) and (3.3) can be written as (see [41, 7])

\[
-\Delta_{gM} \phi = \mathcal{A}(\phi, \phi_{\alpha}) + \text{Re } \mathcal{P}(\mathcal{A}(d\phi(\gamma_\alpha), \gamma_\alpha \cdot \psi) \psi), \quad (3.4)
\]
\[ \phi \psi = \mathcal{A}(d\phi(\gamma_\alpha), \gamma_\alpha \cdot \psi). \]  

Denote
\[ H^1(M, N) := \{ \phi \in H^1(M, \mathbb{R}^K) \mid \phi(x) \in N \text{ a.e. } x \in M \}, \]
\[ \mathcal{W}^{1,\frac{4}{3}}(\Sigma M \otimes \phi^{-1}TN) := \left\{ \psi \in \Gamma(\Sigma M \otimes \phi^{-1}TN) \mid \int_M |\nabla \psi|^\frac{4}{3} < +\infty, \int_M |\psi|^4 < +\infty \right\}. \]

Here, \( \psi \in \Gamma(\Sigma M \otimes \phi^{-1}TN) \), the spinor field along the map \( \phi \), should be understood as an \( n \)-tuple of spinors \( (\psi^1, \psi^2, ..., \psi^n) \) satisfying
\[ \sum_i \nu^i \psi^i = 0, \quad \text{for any normal vector } \nu = \sum_i \nu^i \partial z^i \text{ at } \phi(x), \]
where \( \{z^i, i = 1, 2, ..., n\} \) are the canonical coordinates of \( \mathbb{R}^n \). In the case that \( \dim M = 2 \) we have \( \mathcal{W}^{1,\frac{4}{3}} = W^{1,\frac{4}{3}} \) by Sobolev embedding. It is easy to verify that \( L(\phi, \psi) \) is well defined for \( (\phi, \psi) \in H^1(M, N) \times \mathcal{W}^{1,\frac{4}{3}}(\Sigma M \otimes \phi^{-1}TN) \) (see [39, Remark 1.3]). Denote
\[ \mathcal{X}^{1,2}_{1,\frac{4}{3}}(M, N) := \left\{ (\phi, \psi) \in H^1(M, N) \times \mathcal{W}^{1,\frac{4}{3}}(\Sigma M \otimes \phi^{-1}TN) \right\}, \]
and extend the functional \( L(\cdot, \cdot) \) to the space \( \mathcal{X}^{1,2}_{1,\frac{4}{3}}(M, N) \). Critical points \( (\phi, \psi) \in \mathcal{X}^{1,2}_{1,\frac{4}{3}}(M, N) \) of \( L(\cdot, \cdot) \) are called weakly Dirac-harmonic maps from \( M \) to \( N \) (see [6, 39]).

It is worth remarking that the equation (3.4) can be written as an elliptic system with an \( L^2 \)-antisymmetric structure and hence the Coulomb gauge construction (see appendix D) can be applied to prove the interior continuity of \( \phi \) for any weakly Dirac-harmonic map \( (\phi, \psi) \) from a spin Riemann surface \( M \) into a compact Riemannian manifold \( N \) (see Theorem 2.1 in [7] and Theorem 1.5 in [39]), extending the case of \( N = S^n \) in [6] and the case that \( N \) is a compact hypersurface in \( \mathbb{R}^{d+1} \) in [41].

To see this, consider the case of a domain \( (B_1 \subset \mathbb{R}^m, g_1) \) and apply a similar procedure as in the case of a Euclidean disc done in [41, 7]. Take a local orthonormal basis \( \{\gamma_\alpha, \alpha = 1, ..., m\} \), its dual basis \( \{\theta^\alpha, \alpha = 1, ..., m\} \) and the canonical coordinates \( (z^1, z^2, ..., z^n) \) of \( \mathbb{R}^n \). Let \( \nu_L \), \( L = d + 1, ..., n \) be an orthonormal frame field for the normal bundle \( T^1N \) to \( N \). Denote by \( \nu_L \) the corresponding unit normal vector field along the map \( \phi \). Write \( \phi = \phi^i \partial z^i, \psi = \psi^j \partial z^j \) and denote \( \phi_\alpha = \phi_\alpha(\gamma_\alpha) = \phi_{z^\alpha}, \alpha = 1, ..., m \). Then, similarly to the case of a Euclidean disc considered in [41, 7], the equations (3.4) and (3.5) can be written in the following extrinsic form in terms of the orthonormal frame field \( \nu_L, l = d + 1, ..., n \), for \( T^1N \)

\[ \Delta_\gamma \phi^i = \sum_{k,j,L,\alpha} \left( \phi_\alpha \frac{\partial \nu_k^j}{\partial z^j} \nu_L^j - \phi_\alpha \frac{\partial \nu_k^j}{\partial z^j} \nu_L^j \right) \phi_\alpha^k + \sum_{k,j,L,\alpha} \langle \phi^j, \gamma_\alpha \cdot \psi^j \rangle \left( \frac{\partial \nu_k^j}{\partial z^j} \right) \left( \frac{\partial \nu_L^k}{\partial z^j} \right) \phi_\alpha^k - \left( \frac{\partial \nu_L^k}{\partial z^j} \right) \phi_\alpha^k, \]

(3.6)

\[ \phi \psi^j = \sum_{k,j,L,\alpha} \frac{\partial \nu_k^j}{\partial z^j} \phi_\alpha^k \gamma_\alpha \cdot \psi^j \phi_\alpha^k. \]

(3.7)

Here \( \top \) denotes the orthogonal projection : \( \mathbb{R}^n \rightarrow T_zN \) and \( (\cdot)^i \) denotes the \( i \)-th component of a vector of \( \mathbb{R}^n \). Of course, in general we cannot assume that the normal bundle of \( N \) is trivial, however a simple argument using a partition of unity allows us to consider this case W.L.O.G. In particular let \( \{\chi_\lambda\} \) be a partition of unity such that the normal bundle of \( N \) is trivial over the support of each \( \chi_\lambda \) - let \( \nu_L \) denote a corresponding smooth frame. Now, since the expressions above are independent of the orthonormal normal frame, we are free to cut off any such frame using \( \chi_\lambda \) and summing up we are done - the details are left to the reader or see [25, p.5] for the details in the case of harmonic maps.
Set

\[(\Omega^i_k)_a \theta^a := \left[ \sum_{j,k,L} \left( \phi_{\alpha}^i \frac{\partial \nu^k_j}{\partial z^L} \nu^i_L - \phi_{\alpha}^j \frac{\partial \nu^k_i}{\partial z^L} \nu^j_L \right) \right] \theta^a
+ \left[ \sum_{l,j,k} i (\psi^j, \gamma^j) \left( \frac{\partial \nu^L_l}{\partial z^j} \frac{\partial \nu^k_i}{\partial z^L} - \frac{\partial \nu^L_l}{\partial z^i} \frac{\partial \nu^k_j}{\partial z^L} \right) \right] \theta^a
= (\omega^i_k)_a \theta^a + (F^i_j)_a \theta^a.\]

Then we can write equation (3.6) in the following two equivalent forms:

\[
\Delta_{g_i} \phi^i = (\Omega^i_k)_{a,b} \partial \phi^b \quad (3.8)
\]

\[
\Delta_{g_i} \phi^i = (\omega^i_k)_{a,b} \partial \phi^b + f^i \quad (3.9)
\]

with \( \Omega = ((\Omega^i_k)_a)_{1 \leq i,k \leq n} \in L^2(B_1, so(n) \otimes \Lambda^1 T^* R^m), \omega = ((\omega^i_k)_a)_{1 \leq i,k \leq n} \in L^2(B_1, so(n) \otimes \Lambda^1 T^* R^m) \) and \( f^i := (\tilde{f}^i, \phi^i)_{a,b} \) satisfying

\[
|\Omega(x)| \leq C(|\nabla \phi(x)| + |\psi(x)|^2), \quad \text{for a.e. } x \in B_1^+.
\]

\[
|\omega(x)| \leq C|\nabla \phi(x)|, \quad \text{for a.e. } x \in B_1^+.
\]

\[
|f(x)| \leq C|\psi(x)|^2|\nabla \phi(x)|, \quad \text{for a.e. } x \in B_1^+.
\]

### 3.2 Free boundary value problem for Dirac-harmonic maps from surfaces

In this subsection, we shall recall the free boundary value problem for Dirac-harmonic maps from surfaces introduced in [7].

Let \( M \) be a compact spin Riemann surface with boundary \( \partial M \neq \emptyset \) and let \( S \) be a closed \( s \)-dimensional submanifold of \( N \). Let \( \phi \in C^\infty(M, N) \) be a map from \( M \) to \( N \) and \( \psi \in C^\infty(\Sigma M \otimes \phi^{-1} TN) \) a spinor field along \( \phi \). For the map \( \phi \), we shall impose the free boundary condition for a map in the classical sense, namely, \( \phi(\partial M) \subset S \). For the spinor field \( \psi \), we shall impose the boundary condition using a chirality operator on \( M \) and the geodesic reflection about \( S \).

Firstly, we associate to \( S \) a natural (1, 1) tensor \( R \) on \( S \) that is compatible, namely, for each \( y \in S \), the endomorphism \( R(y) : T_y N \to T_y N \) preserves the metric on \( TN \):

\[
\langle R(y)V, R(y)W \rangle = \langle V, W \rangle, \quad \forall V, W \in T_y N, \quad \forall y \in S,
\]

and it squares to the identity:

\[
R(y)V = V, \quad \forall V \in T_y N, \quad \forall y \in S.
\]

To achieve this, we consider a tubular neighbourhood \( U_{\delta} := \{ y \in N | dist^N(y, S) < \delta \} \) of \( S \) in \( N \), where \( \delta > 0 \) is a constant small enough such that for any \( y \in U_{\delta} \), there exists a unique minimal geodesic \( \gamma_y \) connecting \( y \) and \( y' \in S \) and \( dist(y, y') = dist(y, S) \). Then we define the geodesic reflection \( \sigma \) on \( U_{\delta} \) as follows:

\[
\sigma : U_{\delta} \to U_{\delta}, \quad y \mapsto exp_{y'} v \mapsto \sigma(y) := exp_{y'}(-v),
\]

18
where \( y \in T_y N \) is uniquely determined by \( y \). Clearly, for \( \delta \) small enough, the map \( \sigma \) is a diffeomorphism and there holds \( \sigma^2 = id : U_\delta \to U_\delta \). Now define a \((1, 1)\) tensor \( R \) on \( S \) by

\[
R(y) := D\sigma(y), \quad \forall y \in S.
\]

One can check that the \((1, 1)\) tensor \( R = D\sigma \) is well defined on \( S \) and it satisfies the compatibility properties (3.10), (3.11). This can be easily verified via using some adapted coordinates near \( S \). More precisely, in some neighbourhood \( U \subset U_\delta \) of a given point \( P \in S \), let \( \{y^i\} \) be the Fermi coordinates (or geodesic parallel coordinates) for the submanifold \( S \). Then \( \{y^a\} \) are coordinates in \( S \), \( (y^\lambda)_\lambda \) are the directions normal to \( S \) and

\[
S \cap U = \{ y \in U | y^{s+1} = \ldots = y^d = 0 \}.
\]

In this adapted coordinates, the diffeomorphism \( \sigma \) is given by

\[
\sigma : (y^1, \ldots, y^s, y^{s+1}, \ldots, y^d) \to (y^1, \ldots, y^s, -y^{s+1}, \ldots, -y^d)
\]

and thus there holds

\[
D\sigma(\partial y^i) = \partial y^i, \quad i = 1, \ldots, s
\]

\[
D\sigma(\partial y^j) = -\partial y^j, \quad j = s + 1, \ldots, d.
\]

The tensor \( R \) and the metric \( g \) take the following forms

\[
R = \begin{pmatrix}
\delta^a_b & 0 \\
0 & -\delta^\lambda_\mu
\end{pmatrix}, \quad g = \begin{pmatrix}
g_{ab} & 0 \\
0 & g_{\lambda\mu}
\end{pmatrix}.
\]

Here and in the sequel, we use the following index ranges:

\[
1 \leq a, b, \ldots \leq s, \quad s + 1 \leq \lambda, \mu, \ldots \leq d, \quad 1 \leq i, j, k, \ldots \leq d.
\]

Next, let \( \psi \in C^\infty(S_\phi) \), where \( S_\phi := (\Sigma M \otimes \phi^{-1}TN)|_{\partial M} \) is the restricted (twisted) spinor bundle with induced Hermitian product. Given \( x \in \partial M \), then \( \phi(x) \in \Sigma \). Choose a local orthonormal frame \( \{V_i\} \) on a neighbourhood of \( \phi(x) \) (still denote by \( \{V_i\} \) the corresponding orthonormal frame along the map \( \phi \)). Locally, we can write \( \psi = \sum_i \psi^i \otimes V_i \). Let \( \overrightarrow{\nabla} \) be the outward unit normal vector field on \( \partial M \) and denote by \( Id \) the identity endomorphism acting on \( C^\infty(\phi^{-1}TN|_{\partial M}) \).

Recall that, on the spin Riemann surface \( M \), we have the chirality operator \( G = \gamma(v) \), namely, the Clifford multiplication by the complex volume form \( v = i\gamma_1 \gamma_2 G \) is an endomorphism of the spinor bundle \( \Sigma M \) satisfying:

\[
G^2 = I, \quad (G\psi, G\varphi) = (\psi, \varphi), \quad \nabla_X (G\psi) = G\nabla_X \psi, \quad X \cdot G\psi = -G(X \cdot \psi)
\]

\[
\forall X \in \Gamma(TM), \psi, \varphi \in \Gamma(\Sigma M), \text{ where } I \text{ denotes the identity endomorphism of } \Sigma M. \text{ Then, one can use (3.1), (3.10), (3.11) and (3.13) to verify that the endomorphism } \overrightarrow{\nabla} G \otimes R : C^\infty(S_\phi) \to C^\infty(S_\phi)
\]

is self-adjoint and its square is the identity, namely

\[
((\overrightarrow{\nabla} G \otimes R)\psi, \varphi) = (\psi, (\overrightarrow{\nabla} G \otimes R)\varphi), \quad \forall \psi, \varphi \in C^\infty(S_\phi)
\]

\[
(\overrightarrow{\nabla} G \otimes R)^2 = I \otimes Id.
\]
Decompose the bundle $S_\phi = V^+_\phi \oplus V^-_\phi$ into the two eigen-subbundles corresponding to the eigenvalues $\pm 1$. The chirality boundary condition $B^\pm_\phi$ for the Dirac operator $\mathcal{D}$ along $\phi$ is defined by taking the orthogonal projection onto the eigen-subbundle $V^\pm_\phi$:

$$B^\pm_\phi : C^\infty(S_\phi) \to C^\infty(V^\pm_\phi)$$

$$\psi \mapsto \frac{1}{2} (I \otimes I d \pm \overrightarrow{n} G \otimes R) \psi.$$ 

We say a spinor field $\psi \in C^\infty(\Sigma M \otimes \phi^{-1} TN)$ along a map $\phi$ satisfies one of the boundary conditions $B^\pm_\phi$ if

$$B^\pm_\phi \psi|_{\partial M} = 0. \quad (3.14)$$

Equation (3.14) is a generalisation of the (usual) chirality boundary condition for the (usual) Dirac operator $\mathcal{D}$ (see [20]):

$$B^\pm : C^\infty(S) \to C^\infty(V^\pm)$$

$$\omega \mapsto \frac{1}{2} (I \pm \overrightarrow{n} G) \omega,$$

and the boundary condition is

$$B^\pm \omega|_{\partial M} = 0 \quad (3.15)$$

where $S := \Sigma M|_{\partial M} = V^+ \oplus V^-$. 

To reformulate the boundary condition (3.14) in terms of local coordinates, we first consider the usual chirality condition for standard spinor fields on $M = \mathbb{R}^2_+ \oplus \mathbb{C}^2$ equipped with the Euclidean metric $dx_1^2 + dx_2^2$. Let $\gamma_\alpha = \partial x_\alpha, \alpha = 1, 2$ be the standard orthonormal frame. A spinor field on $\mathbb{R}^2_+$ is simply a section $\omega \in \Gamma(\Sigma \mathbb{R}^2_+ = \mathbb{R}^2_+ \times \mathbb{C}^2)$ given by $\omega = \begin{pmatrix} \omega_1 \\ \omega_2 \end{pmatrix} : \mathbb{R}^2_+ \to \mathbb{C}^2$ and the Clifford multiplication of $\gamma_\alpha, \alpha = 1, 2$ acting on spinors can be seen as matrix multiplication with the following identification:

$$\gamma_1 \rightarrow \begin{pmatrix} 0 & i \\ i & 0 \end{pmatrix}, \quad \gamma_2 \rightarrow \begin{pmatrix} 0 & 1 \\ -1 & 0 \end{pmatrix}. \quad (3.16)$$

Here, W.L.O.G., we keep the representations of $\gamma_1$ and $\gamma_2$ consistent with those in [7]. If exchanging $\gamma_1$ and $\gamma_2$, then their representations are consistent with those in [5] and this case can be handled analogously.

The usual Dirac operator $\mathcal{D}$ is therefore given by

$$\mathcal{D} \omega = \gamma_\alpha \cdot \nabla_{\gamma_\alpha} \omega = \begin{pmatrix} 0 & i \\ i & 0 \end{pmatrix} \begin{pmatrix} \frac{\partial \omega_1}{\partial x_1} \\ \frac{\partial \omega_1}{\partial x_2} \end{pmatrix} + \begin{pmatrix} 0 & 1 \\ -1 & 0 \end{pmatrix} \begin{pmatrix} \frac{\partial \omega_2}{\partial x_1} \\ \frac{\partial \omega_2}{\partial x_2} \end{pmatrix} = 2i \begin{pmatrix} \frac{\partial \omega_1}{\partial x_1} \\ \frac{\partial \omega_1}{\partial x_2} \end{pmatrix}. \quad (3.17)$$

Take the chirality operator $G := i\gamma_1 \gamma_2 = \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix}$. Note that $\overrightarrow{n} = -\partial x_2 = -\gamma_2 = \begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix}$, and hence we can calculate $\overrightarrow{n} \cdot G = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}$. By the standard chirality decomposition (see e.g. [24]), we write

$$\omega = \frac{1}{2}((I d + G)\omega + (I d - G)\omega) = \begin{pmatrix} \omega_+ \\ \omega_- \end{pmatrix}.$$ 

Then, the chirality boundary condition (3.15) becomes:

$$\omega_+ = \mp \omega_- \quad \text{on } \partial M.$$
Similarly, for a spinor field (along a map) \( \psi = \psi^i \otimes \partial_i \), we write \( \psi^i = \left( \frac{\psi^i_+}{\psi^i_-} \right) \). Then, the chirality boundary condition (3.14) becomes:

\[
\psi^i_+ = \mp R^i_j \psi^j_- , \quad i = 1, 2, \cdots, d , \quad \text{on } \partial M
\]

(3.18)

which is equivalent to (by (3.12))

\[
\psi^i_+ = \mp \eta^i \psi^i_- , \quad i = 1, 2, \cdots, d , \quad \text{on } \partial M,
\]

where \( \eta_i := \left\{ \begin{array}{ll} 1, & i = 1, \ldots, s, \\ -1, & i = s + 1, \ldots, d. \end{array} \right. \)

Set

\[
X(M, N; \mathcal{S}) := \left\{ (\phi, \psi) | \phi \in C^\infty(M, N), \phi(\partial M) \subset \mathcal{S}; \psi \in C^\infty(\Sigma M \otimes \phi^{-1}TN), B^\perp_S \psi|_{\partial M} = 0 \right\}.
\]

A critical point \((\phi, \psi)\) of \(L(\cdot, \cdot)\) in \(X(M, N; \mathcal{S})\) is called a Dirac-harmonic map from \(M\) to \(N\) with free boundary \(\phi(\partial M)\) on \(\mathcal{S}\).

Let \((\phi, \psi)\) be a Dirac-harmonic map from \(M\) to \(N\) with free boundary \(\phi(\partial M)\) on \(\mathcal{S} \subset N\). As is done in [7, p.1011-1012], using local coordinates \(\{g^j\}_{j=1}^d\), we can take the following two types of admissible variations \((\phi_t, \psi_t) \in X(M, N; \mathcal{S})\):

i) \(\phi_t \equiv \phi\) and \(\frac{d\phi_t}{dt}|_{t=0} = \xi\) is arbitrary;

ii) \(\frac{d\phi_t}{dt}|_{t=0} = \eta\) is arbitrary and \(\psi_t = \psi^j_t \otimes \partial_i(\phi_t)\) with \(\psi^j_t \equiv \psi^j\)

and applying direct calculations from calculus of variations to obtain the following boundary constraint:

\[
\left(2\phi^j_{\partial^j} - g^{in}(\overrightarrow{\nabla} \cdot \psi^i, \psi^j)\Gamma^k_{in}g^k_j\right)\partial_j \perp \mathcal{S} , \quad \text{on } \partial M.
\]

(3.19)

where \(\partial_j := \frac{\partial}{\partial x^j}\).

Furthermore, in terms of the Fermi coordinates \(\{g^i\}_{i=1}^d\) about \(\mathcal{S}\), we are able to reformulate (3.19) into a simpler form. We shall proceed as in [7, p.1012]. By the chirality boundary condition (3.14) (see also (3.18)) for \(\psi\), there hold:

\[
\langle \overrightarrow{\nabla} \cdot \psi^a, \psi^b \rangle = 0, \quad \langle \overrightarrow{\nabla} \cdot \psi^\lambda, \psi^\mu \rangle = 0 , \quad \text{on } \partial M
\]

(3.20)

for \(a, b = 1, 2, \ldots, s\) and \(\lambda, \mu = s + 1, \ldots, d\). Since \(g_{\lambda \mu} = 0\) (see (3.12)), one can verify that

\[
g_{ab}\Gamma^a_{\lambda \mu} = -g_{\lambda \mu}\Gamma^a_{bn}.
\]

(3.21)

By (3.1), (3.20) and (3.21), we have

\[
g^{in}g^k_j\Gamma^i_{kn}(\overrightarrow{\nabla} \cdot \psi^i, \psi^j) = g^{jn}g_{\lambda \mu}\Gamma^i_{jn}(\overrightarrow{\nabla} \cdot \psi^i, \psi^j) + g^{jn}g_{\lambda \mu}\Gamma^i_{jn}(\overrightarrow{\nabla} \cdot \psi^i, \psi^j)
\]

\[
= g^{jn}g_{\lambda \mu}\Gamma^i_{jn}(\overrightarrow{\nabla} \cdot \psi^i, \psi^j) + g^{jn}g_{\lambda \mu}\Gamma^i_{jn}(\overrightarrow{\nabla} \cdot \psi^i, \psi^j)
\]

\[
= g^{jn}g_{\lambda \mu}\Gamma^i_{jn}(\overrightarrow{\nabla} \cdot \psi^i, \psi^j) + g^{jn}g_{\lambda \mu}\Gamma^i_{jn}(\overrightarrow{\nabla} \cdot \psi^i, \psi^j)
\]

\[
= g^{jn}g_{\lambda \mu}\Gamma^i_{jn}(\overrightarrow{\nabla} \cdot \psi^i, \psi^j) + g^{jn}g_{\lambda \mu}\Gamma^i_{jn}(\overrightarrow{\nabla} \cdot \psi^i, \psi^j)
\]

\[
= 2g^{jn}g_{\lambda \mu}\Gamma^i_{jn}(\overrightarrow{\nabla} \cdot \psi^i, \psi^j) , \quad \text{on } \partial M.
\]
\[ \left( \frac{\partial \phi}{\partial n} \right)^{\top} = g^{cd} \Gamma_{ad}^{\lambda} \text{Re}(\langle n, \psi^\mu \rangle) \partial_c \quad \text{on } \partial M. \]  

(3.22)

Let \( P_{\mathcal{S}}(\cdot, \cdot) \) be the shape operator of \( \mathcal{S} \) in \( N \) and define \( \mathcal{P}_S(\psi^\mu \otimes \partial_a; \psi^a \otimes \partial_a) := P_S(\partial_a; \partial_a)(\psi^\mu, \psi^a) \). Then (3.22) is equivalent to

\[ \left( \frac{\partial \phi}{\partial n} \right)^{\top} = \text{Re}(\mathcal{P}_S(\langle n, \psi^{\perp} \rangle \cdot \psi^{\perp})), \quad \text{on } \partial M. \]  

(3.23)

Here \( \psi^{\perp} \) denotes the normal part of \( \psi \) and \( \psi^{\perp} \) denotes the tangent part of \( \psi \).

To summarise, we have the following equivalent definition:

**Definition 3.1** ([7], Definition 3.2). \((\phi, \psi) \in \mathcal{X}(M, N; S)\) is called a Dirac-harmonic map from \( M \) to \( N \) with free boundary \( \phi(\partial M) \) on \( S \subset N \) if \((\phi, \psi)\) is Dirac-harmonic in \( M \) - namely they solve (3.2), (3.3) in \( M \) - and they satisfy the boundary conditions (3.14), (3.23).

**Free boundary conditions for weakly Dirac-harmonic maps from surfaces**

As in [7, p.1013-1014], using the isometric embedding \( N \subset \mathbb{R}^n \) and the orthogonal decomposition \( \mathbb{R}^{\mathbb{R}}_\phi = T_y(N \oplus T^\perp_y N) \), for \( y \in N \), we can consider the bundles \( \phi^{-1}TN, \Sigma M \otimes \phi^{-1}TN \) and \( S_\phi = (\Sigma M \otimes \phi^{-1}TN)|_{\partial M} \) as sub-bundles of \( \phi^{-1}T\mathbb{R}^n, \Sigma M \otimes \phi^{-1}T\mathbb{R}^n \) and \( (\Sigma M \otimes \phi^{-1}T\mathbb{R}^n)|_{\partial M} \), respectively. Moreover, we consider the space \( L^2(S_\phi) = \{ \psi|\partial M : \psi \in W^{1,2}(\Sigma M \otimes \phi^{-1}TN) \} \).

For \( \delta > 0 \) small enough, take a tubular neighbourhood \( V_{3\delta}N \) of \( N \) in \( \mathbb{R}^n \) with a projection \( P : V_{3\delta}N \to N \). Define \( \hat{R}(y) := D(\sigma \circ P)(y), \) for \( y \in S \). The following compatibility properties (similar to (3.10) and (3.11)) hold

\[ \langle \hat{R}(y)V, \hat{R}(y)W \rangle_{\mathbb{R}^n} = \langle V, W \rangle_{\mathbb{R}^n}, \quad \hat{R}(y)\hat{R}(y)V = V, \quad \forall V, W \in T_y N, \forall y \in S. \]

Analogously to the smooth case, the endomorphism \( \overline{n}G \otimes \hat{R} : L^2(S_\phi) \to L^2(S_\phi) \) is self-adjoint and squares to the identity. Decomposing \( S_\phi = V_\phi^\perp \oplus V_\phi^\parallel \), we define a (local elliptic) boundary condition \( \hat{B}_\phi^\pm : L^2(S_\phi) \to L^2(V_\phi^\pm) \) for \( \mathcal{D} \). For simplicity of notation, in the sequel, we shall still use \( B_\phi^\pm \) to denote \( \hat{B}_\phi^\pm \). Set

\[ \mathcal{X}_{1,2}^{\pm}(M, N; S) := \left\{ (\phi, \psi) \in H^1(M, N) \times W^{1,2}(\Sigma M \otimes \phi^{-1}TN) : \psi(x) = 0 \text{ for a.e. } x \in \partial M \right\}. \]

A critical point \((\phi, \psi)\) of \( L(\cdot, \cdot) \) in \( \mathcal{X}_{1,2}^{\pm}(M, N; S) \) is called a weakly Dirac-harmonic map with free boundary \( \phi(\partial M) \) on \( S \).

**Proposition 3.2.** Let \((\phi, \psi) \in \mathcal{X}_{1,2}^{\pm}(M, N; S)\) be a weakly Dirac-harmonic map with free boundary \( \phi(\partial M) \) on \( S \). Suppose that \( \phi \) maps \( M \) into a single coordinate neighbourhood \{\( y^i \}_{i=1}^d \} \subset N \) and hence our spinor can be expressed as \( \psi = \sum_{i=1}^d \psi^i \otimes \partial_i(\phi) \). Then

\[ \int_M \langle d\phi, \nabla \psi \rangle V + \int_M \langle \psi^k, \gamma \cdot \psi^i \rangle (\mathcal{R}_{\phi}^{\mathcal{S}}(\gamma) \partial_h, V) = \int_{\partial M} \frac{1}{4} \langle \partial^k (\partial^l, \psi^i, \psi^j) (g^{in} \Gamma_{aij} \partial_l, V) \rangle \]  

(3.24)

for all \( V \in H^1 \cap L^\infty(M, \phi^{-1}TN) \) such that \( V(x) \in T_\phi(x)S \) for a.e. \( x \in \partial M \) and for all \( \xi \in W^{1,2} \cap L^\infty(\Sigma M \otimes \phi^{-1}TN) \) such that \( B_\phi^\pm \xi|_{\partial M} = 0 \).
In particular, in terms of Fermi coordinates \( \{y^i\}_{i=1}^d \) about \( S \), (3.24) becomes
\[
\int_M \langle d\phi, \nabla^\phi V \rangle + \int_M \langle \psi^k, \gamma_\alpha \cdot \psi^l \rangle \langle R^h_{jkl} \phi^*_\alpha(\gamma_\alpha) \partial_h, V \rangle = \int_{\partial M} (\text{Re}(\overline{\phi} \cdot \phi^\alpha)) (g^d \Gamma^\lambda_{ad} g_{\lambda \mu} \partial_\mu, V).
\]

**Proof:** Since we can use local coordinates \( \{y^i\}_{i=1}^d \) on the target, similarly to the smooth case (see [7, p.1011-1012]), we can take two types of admissible variations \( (\phi_t, \psi_t) \in \mathcal{X}^{1,2}_{1, \frac{d}{2}}(M, N; S) \) and apply direct calculations to complete the proof. \[\square\]

**Remark 3.3.** The condition that \( \phi \) maps into a single coordinate neighbourhood of \( N \) seems rash until one considers Lemma 4.4. Notice that since \( \psi \in W^{1,2} \) we have that \( \psi \in L^2(\partial M) \) in a trace sense, moreover since \( V \in W^{1,2} \cap L^\infty \) when we take a trace in the \( W^{1,2} \) sense (not necessarily bounded) we actually must have that the trace is bounded. Moreover the operator \( \nabla^\phi \) is of course the pull back Levi-Civita connection on \( \phi^{-1}TN \).

## 4 Regularity and smooth estimates

In this section, we first show the interior smooth estimates in all dimensions \( m \geq 2 \), Theorem 1.10 and Theorem 1.12. Then, we prove the full regularity and smooth estimates at the free boundary for weakly Dirac-harmonic maps in dimension \( m = 2 \), Theorems 1.6 and Theorem 1.8.

### 4.1 Interior estimates in all dimensions, the proof of Theorems 1.10 and 1.12

We begin by proving the two dimensional result Theorem 1.10 by first showing that the equation solved by the spinor, (3.7) is sub-critical. Then a simple application of [37, Theorem 1.1] - or Theorem 2.1 for \( A - Id \equiv \zeta \equiv 0 \) and \( m = 2 \) - puts us in the position of being able to apply a simple bootstrapping argument.

We now state a standard \( \epsilon \)-regularity theorem for solutions to a linear Dirac system of spinors in two dimensions:

**Theorem 4.1.** Let \( B_1 \subset \mathbb{R}^2 \) and \( \psi \in L^4(B_1, C^2 \otimes \mathbb{R}^d), \Gamma \in L^2(B_1, gl(d) \otimes \wedge^1 \mathbb{R}^2) \) solve
\[
\phi \psi = \Gamma_\alpha \gamma_\alpha \cdot \psi \quad \text{on} \quad B_1.
\]

Then for any \( 2 \leq q < \infty, \psi \in W^{1, \frac{2}{q}}_{\text{loc}} \) and there exist \( \epsilon = \epsilon(q) > 0 \) and \( C = C(q) > 0 \) such that whenever
\[
\|\Gamma\|_{L^q(B_1)} \leq \epsilon
\]
then
\[
\|\psi\|_{L^q(B_{\frac{1}{4}})} + \|\nabla \psi\|_{L^{\frac{2q}{q-1}}(B_{\frac{1}{4}})} \leq C\|\psi\|_{L^q(B_1)}.
\]

**Proof of Theorem 4.1:** The proof of such a theorem is now standard and is essentially contained in [38] so we only provide a sketch: apply the Dirac operator to both sides of our PDE to give that \( \psi \) weakly solves
\[
\Delta \psi = \mathcal{D}^2(\psi) = \partial (\Gamma_\alpha \gamma_\alpha \cdot \psi)
\]
by Lichnerowicz’s formula [24]. Now, by extending \( \psi \) and \( \Gamma \) by zero and setting \( V := N[\partial (\Gamma_\alpha \gamma_\alpha \cdot \psi)] \) where \( N \) is the Newtonian potential, we have that
\[
|V| \leq I_1[|\Gamma_\alpha \gamma_\alpha \cdot \psi|]
\]

23
where $I_1$ is the Riesz potential of order one - see [38, p.3755-3756]. By standard estimates, see [43, Theorem 2.8.4], we have
\[
\|V\|_{L^4} \leq C\|\Gamma\|_{L^2}\|\psi\|_{L^4}.
\]
Now, setting $k := V - \psi$ we have that $\Delta k = 0$ in $B_1$ and $k \in L^4$ yielding (see [18, Lemma 3.3.12])
\[
\|k\|_{L^4(B_1)} \leq r^{\frac{3}{2}}\|k\|_{L^4(B_{3r})} \leq r^{\frac{3}{2}}(C\|\Gamma\|_{L^2}\|\psi\|_{L^4} + \|\psi\|_{L^4(B_1)}).
\]
Therefore
\[
\|\psi\|_{L^4(B_r)}^4 \leq \left(\|V\|_{L^4(B_1)} + \|k\|_{L^4(B_{3r})}\right)^4 \leq (C\|\Gamma\|_{L^2}\|\psi\|_{L^4(B_1)} + r^{\frac{3}{2}}\|\psi\|_{L^4(B_1)})^4 \leq (1 + \delta)r^{\frac{3}{2}}\|\psi\|_{L^4(B_1)} + C\delta^4\|\psi\|_{L^4(B_1)}^4
\]
by Young’s inequality. Let $0 < \nu < 2$ and first set $\delta > 0$ and then $\epsilon > 0$ small enough so that
\[
\theta := \frac{1 + \delta + 4C\delta^4}{4} = \left(\frac{1}{2}\right)^\nu.
\]
Now by a re-scaling argument we have
\[
\|\psi\|_{L^4(B_{\frac{r}{\theta}})}^4 \leq \theta\|\psi\|_{L^4(B_r)}^4.
\]
Given $r < 1$ we can find $k$ such that
\[
2^{-(k+1)} \leq r \leq 2^{-k}
\]
and we have
\[
\|\psi\|_{L^4(B_r)}^4 \leq \|\psi\|_{L^4(B_{2^{-k}})}^4 \leq \theta^k\|\psi\|_{L^4(B_1)}^4.
\]
From here using standard techniques we can conclude that for all $2 > \nu > 0$ there exists $\epsilon > 0$ such that
\[
\|\psi\|_{M^{\nu,2-\nu}(B_{\frac{r}{\theta}})} \leq C\|\psi\|_{L^4(B_1)}.
\]
Now this gives $\Gamma\psi \in M^{1,\frac{8}{7}}_{\text{loc}}$. Setting $\nu := \frac{16}{30-\frac{4}{7}}$ and again the Riesz potential estimates of Adams [1] gives $V \in M^q_{\text{loc}}$ yielding the appropriate estimate and eventually giving the proof.

**Proof of Theorem 1.10:** Looking back at (3.7) and setting $\Gamma_{j,\alpha} = \sum_{k,l} \frac{\partial \phi_k}{\partial x_j} \partial_{\alpha} \phi^k$ we have
\[
|\Gamma(x)| \leq C|\nabla \phi(x)|
\]
and therefore, we fix $q > 4$ and conclude that if $\|\nabla \phi\|_{L^2}$ is sufficiently small then $\psi \in L^q_{\text{loc}}(B_1)$ with the appropriate estimate from Theorem 4.1. Next consider equation (3.9) with $(g_1)_{ij} = \delta_{ij}$; we have $f \in L^p$ for some $1 < p < 2$ and
\[
\|f\|_{L^p(B_\frac{1}{4})} \leq C\|\nabla \phi\|_{L^2(B_1)}(1 + \|\psi\|_{L^4(B_1)}).
\]
Now, applying [37, Theorem 1.1], or indeed Theorem 2.1 (for $m = 2$, $\Omega = \omega$, $A \equiv Id$, $\zeta \equiv 0$) and noting that $|\omega(x)| \leq C|\nabla \phi(x)|$ tells us that when $\|\nabla \phi\|_{L^2(B_1)}$ is sufficiently small then we have (see remark 2.2)
\[
\|\phi\|_{W^{2,p}(B_{\frac{1}{4}})} \leq C\|\nabla \phi\|_{L^2(B_1)}(1 + \|\psi\|_{L^4(B_1)}).
\]
We leave the rest of the proof to the reader since it is a simple bootstrapping argument using (3.6) and (3.7).
Proof of Theorem 1.12: Consider now equation (3.8) for \((g_1)_{ij} = \delta_{ij}\) and notice that we have
\[
|\Omega(x)| \leq C (|\nabla \phi(x)| + |\psi(x)|^2).
\]

Thus we can apply [36, Corollary 1.3], also in [35, Corollary 6.2.2] or equivalently Theorem 2.1 for \(A - Id \equiv \zeta \equiv f \equiv 0\) giving that (fixing \(q > 4\)) there exists an \(\epsilon > 0\) such that if \(\|\nabla \phi\|_{M^{2,m-2}(B_1)} + \|\psi\|_{M^{4,m-2}(B_1)} \leq \epsilon\) then \(\nabla \phi \in M^{4,m-2}_{loc}(B_1)\) with the appropriate estimate - see remark 2.2 for some details if necessary. We give a brief outline of the rest of the proof since it is essentially a standard boot-strapping argument but with some perhaps non-standard spaces.

Since \(\nabla \phi \in M^{d,2,m-2}_{loc}(B_1)\), checking (3.7), coupled with the fact that \(\psi \in M^{4,m-2}\) gives \(\partial \psi \in M^{4,m-2}_{loc}\) for \(\frac{1}{q} = \frac{1}{4} + \frac{1}{q}\) and \(s > 2\) since \(q > 4\). Thus we have \(\nabla \psi \in M^{s,m-2}_{loc}\) since Morrey spaces are preserved under singular integral transformations - see [26]. Now, one can easily use the Poincaré inequality and some standard facts about Morrey-Campanato spaces (see [12] or [35, p.33-34]) to conclude \(\psi \in C^{0,1/4}_{loc}\) with an estimate. Looking back at (3.6) we see that the worst term on the right hand side is quadratic in \(\nabla \phi\), which we can control in \(M^{d,2,m-2}_{loc}(B_1)\), therefore we have \(\nabla^2 \phi \in M^{d,2,m-2}_{loc}(B_1)\). Since \(q > 4\) and using a similar argument as above we can conclude \(\nabla \phi \in C^{0,1/4}_{loc}(B_1)\). We now leave the rest of the details to the reader since they follow from a straightforward bootstrapping argument using (3.6) and (3.7).

When \(m = 2\), since the problem is conformally invariant we can use Theorem 1.10 to conclude the following:

**Corollary 4.2.** Let \((M^2, g)\) be a closed Riemann surface and \((N^d, h)\) a closed Riemannian manifold with \(d \geq 2\). Let \((\phi, \psi)\) be a weakly Dirac-harmonic map from \((M, g)\) to \((N, h)\), then it is smooth. Moreover for any \(k \in \mathbb{N}\), there exist \(\epsilon = \epsilon(M, N) > 0\) and \(C = C(M, N, k) > 0\) such that whenever
\[
\int_{B^M(x_0)} |\nabla \phi|^2 dV_g \leq \epsilon^2
\]
for some \(x_0 \in M\) and \(0 < r \leq \frac{1}{4}\), then
\[
\|\nabla^k \phi\|_{L^\infty(B_{r/2}(x_0))} + r^\frac{k}{2} \|\nabla^k \psi\|_{L^\infty(B_{r/2}(x_0))} \leq C r^{-k} \|\nabla \phi\|_{L^2(B_r(x_0))} (1 + \|\psi\|_{L^4(B_r(x_0)))}.
\]

Here we have denoted intrinsic geodesic balls by \(B^M\).

We can couple Theorem 1.12 with Remark 1.13 and recover the following result (see [39, Theorem 1.4]):

**Corollary 4.3.** Let \((M^m, g)\) be a closed spin Riemannian manifold and \((N^d, h)\) a closed Riemannian manifold with \(m, d \geq 2\). For any \(k \in \mathbb{N}\), there exist \(\epsilon = \epsilon(M, N) > 0\) and \(C = C(M, N, k) > 0\) such that if \((\phi, \psi)\) is a weakly Dirac-harmonic map from \((M, g)\) to \((N, h)\) and for some \(x_0 \in M\) and \(0 < r_0 \leq \frac{1}{4}\) there holds
\[
\sup_{x \in B^M_{r_0}(x_0), 0 < r \leq r_0} \left\{ \frac{1}{r^{m-2}} \int_{B^M_r(x)} (|\nabla \phi|^2 + |\psi|^4) dV_g \right\} \leq \epsilon^2
\]
then \((\phi, \psi)\) is smooth in \(B^{M}_{r_0}(x_0)\) and the following estimates hold:
\[
\|\nabla^k \phi\|_{L^\infty(B_{r/2}(x_0))} + r^\frac{k}{2} \|\nabla^k \psi\|_{L^\infty(B_{r/2}(x_0))} \leq C r^{-k} (\|\nabla \phi\|_{M^{2,m-2}(B_r(x_0))} + \|\psi\|_{M^{4,m-2}(B_r(x_0))}).
\]

25
4.2 Localisation at the free boundary in the domain and target

Let $M$ be a compact spin Riemann surface and let $(\phi, \psi) \in X^{1,2}_{1,2}(M, N; S)$ be a weakly Dirac-harmonic map with free boundary $\phi(\partial M)$ on $S$. By conformal invariance in dimension $m = 2$, for simplicity, we shall locate our problem in a small neighbourhood of a boundary point and consider the case that the domain is $B^+_1 := \{(x_1, x_2) \in \mathbb{R}^2 | x_1^2 + x_2^2 < 1, x_2 \geq 0\}$ and the free boundary portion is $I := \{(x_1, 0) \in \mathbb{R}^2 | -1 < x_1 < 1\}$. Moreover, we take $\gamma_\alpha = \partial x_\alpha, \alpha = 1, 2$.

It turns out that one can also localise the problem in the target. To see this, we give the following lemma, which is an improved version of Lemma 3.1 in [7], showing that the image of $\phi$ is contained in a small neighbourhood of some point $q \in S$ under a smallness condition.

**Lemma 4.4.** Let $N$ be a compact Riemannian manifold, isometrically embedded in $\mathbb{R}^n$ and $S \subset N$ a closed submanifold. Then there exists some $\tilde{\epsilon}_0 = \epsilon_0(N) > 0$ such that if $(\phi, \psi) \in X^{1,2}_{1,2}(B^+_1, N; S)$ is a weakly Dirac-harmonic map with free boundary $\phi(I)$ on $S$ satisfying

$$\|\nabla \phi\|_{L^2(B^+_1)} \leq \tilde{\epsilon}_0$$

then

$$\text{dist}(\phi(x), S) \leq C(1 + \|\psi\|_{L^4(B^+_1)})\epsilon_0 \quad \text{for all } x \in B^+_{1/4}$$

with a constant $C = C(N) > 0$. Moreover, there is a $q \in S$ such that $\phi(x) \in B_{C\epsilon_0}(q)$ for all $x \in B^+_{1/4}$ with $C := C(N)(1 + \|\psi\|_{L^4(B^+_1)})$.

**Proof of Lemma 4.4:** By the proof of Lemma 3.1 in [7] it is sufficient to prove that given any $x_0 \in B^+_{1/4} \setminus I$ and $R := \frac{1}{2}\text{dist}(x_0, I)$ then there exists a $C = C(N) > 0$ with

$$|\nabla \phi(x)| \leq \frac{C(1 + \|\psi\|_{L^4(B^+_1)})\epsilon_0}{R}$$

for all $x \in B^+_{2R}(x_0)$. This follows simply by applying the interior estimate from Corollary 4.2 which gives that there exists a $C = C(N) > 0$ with

$$|\nabla \phi(x)| \leq \frac{C\|\nabla \phi\|_{L^2(B^+_{3R}(x_0))}(1 + \|\psi\|_{L^4(B^+_{3R}(x_0))})}{R}$$

for all such $x$. \qed

**Remark 4.5.** There exists some $\hat{r} = \hat{r}(N, S) > 0$ such that for any $q \in S$, there are Fermi coordinates $\{y^i\}$ for $S \subset N$ on $B^+_1(q)$ - we can find such a radius $\hat{r}$ since $S \subset N$ is closed. Therefore setting $\epsilon_0 := \frac{\hat{r}(N, S)(1 + \|\psi\|_{L^4(B^+_1)})}{C(N)(1 + \|\psi\|_{L^4(B^+_1)})}$ in the above lemma we can always ensure that $\phi$ maps into a Fermi-coordinate neighbourhood in the target.

4.3 Regularity and smooth estimates at the free boundary for weakly Dirac-harmonic maps from surfaces

By conformal invariance in dimension $m = 2$ and setting $\epsilon_0$ in Lemma 4.4 sufficiently small (see remark 4.5), we can W.L.O.G assume that $\phi(B^+_1) \subset U$, where $U$ is a ball in $N$ centred at a point $q \in S$ and with Fermi coordinates $\{y^i\}_{i=1}^d$ about $S$, therefore from now on we think of $U \subset \mathbb{R}^d$ as being some bounded domain. Note that we are now in the set-up of Proposition 3.2.

We shall use an orthonormal frame to express the terms appearing there: Recall that the matrix $(g_{ij}) = ((\partial_i, \partial_j)g)$ has block form (see (3.12))

$$g = \begin{pmatrix} g_{ab} & 0 \\ 0 & g_{\lambda\mu} \end{pmatrix}.$$
Applying Gram-Schmidt orthonormalisation to the two frames \( \{ \partial_j \}_{j=1}^s \) and \( \{ \partial_{\mu} \}_{\mu=s+1}^d \), we obtain two smooth orthonormal frames \( \tilde{e}_a = \hat{A}_a^\mu \partial_{\mu} \) and \( \tilde{e}_\lambda = \hat{A}_\lambda^\mu \partial_{\mu} \), respectively. Here \( (\hat{A}_a^\mu) \in C^\infty(U,GL(p)) \) and \( (\hat{A}_\lambda^\mu) \in C^\infty(U,GL(d-p)) \). Clearly we have that \( (\tilde{e}_a, \tilde{e}_\lambda)_{1 \leq a \leq s, s+1 \leq \lambda \leq d} \) form a smooth orthonormal frame with respect to \( g \). Let now

\[
\hat{\Omega}_j^i := (\tilde{e}_i, \nabla^N \tilde{e}_j)
\]

be the connection form for the Levi Civita connection on \( TN \) over \( U \) with respect to the frame \( \{ \tilde{e}_1 \} \), noting that it is antisymmetric.

Denote

\[
\hat{A} := \begin{pmatrix} \hat{A}_a^\mu & 0 \\ 0 & \hat{A}_\lambda^\mu \end{pmatrix}
\]

and set \( A(x) = (\hat{A}(\phi(x)))^{-1} \), then \( A \in W^{1,2} \cap L^\infty(B_1^+,GL(d)) \) and \( A^{-1} \in W^{1,2} \cap L^\infty(B_1^+,GL(d)) \). It is easy to see that \( A \) commutes with \( R \) and there exist \( \Lambda = \Lambda(N,S) > 0 \) and \( C = C(N,S) > 0 \) such that

\[
\Lambda^{-1} |\xi| \leq |A(x)\xi| \leq \Lambda |\xi|
\]

and

\[
|\nabla A(x)| \leq C |\nabla \phi(x)|
\]

for almost every \( x \in B_1^+ \) and for all \( \xi \in \mathbb{R}^d \).

Set \( e_i(x) = \tilde{e}_i(\phi(x)) \), \( i = 1, 2, ..., d \) and

\[
\Omega_j^i := \phi^* \hat{\Omega}_j^i \in L^2(B_1^+, so(d) \otimes \wedge^1 \mathbb{R}^2)
\]

then \( \{ e_i \}_{i=1}^d \subset W^{1,2} \cap L^\infty(B_1^+, \mathbb{R}^d) \) is an orthonormal frame with respective connection forms \( \Omega \) for \( \phi^{-1}TN = B_1^+ \times \mathbb{R}^d \), and there exists \( C = C(N,S) > 0 \) such that

\[
|\Omega(x)| \leq C |\nabla \phi(x)|, \quad \text{for a.e. } x \in B_1^+
\]

Consider \( \eta \in C^\infty_c(B_1^+ \cup I, \mathbb{R}^d) \) satisfying

\[
\eta^i = 0 \quad \text{on } I, \quad \text{when } s+1 \leq i \leq d
\]

and set \( V := \eta^i e_i \): notice that \( V \) is tangent to \( S \) along \( I \) and is as in Proposition 3.2. We can now write

\[
\nabla^\phi V = d\eta^i e_i + \eta^i \Omega_j^i e_i.
\]

Moreover we can write

\[
\partial y^i(\phi(x)) = A_j^i(x) e_j(x)
\]

and therefore we set

\[
f^n := -A^n_k g^{ij} R_{ijkl} \phi^j(\gamma_\alpha, \gamma_\alpha, \psi^j)
\]

\[
\Phi^n := A^n_k g^{cd} \Lambda_{d\alpha} R_{\alpha k \mu} \Re((\overline{\partial} \psi^c, \psi^a))
\]

and noting that

\[
d\phi = A_k^i d\phi^i e_k
\]

we have

\[
\int_M (\Phi^n e_n, \eta^i e_i) - \int_M (f^n e_n, \eta^i e_i) = \int_{\partial M} (\Phi^n e_n, \eta^i e_i)
\]

and since \( \Omega^T = -\Omega \) and \( e_i \) is an orthonormal frame we can write

\[
\int_M (Ad\phi, d\eta) = \int_M (\Omega, Ad\phi) + f, \eta) + \int_{\partial M} (\Phi, \eta)
\]

27
which holds for any such $\eta$. Notice that $g^n = 0$ for $s + 1 \leq n \leq d$ by definition and the properties of $A$ - and we have once again denoted $\mathcal{G} := (g^1, \ldots, g^n, 0, \ldots 0)$. Moreover by our choice of coordinates we have
\[
\phi^i = 0 \quad \text{on } I, \text{ when } s + 1 \leq i \leq d.
\]
Clearly now we would like to apply Theorem 1.2, however we have $f \in L^1$ and $\mathcal{G} \in W^{1,1}_\partial(I)$ so we first improve the regularity of our spinor.

Claim: For any $\frac{1}{3} < r < 2$ we have $\psi \in W^{1, r}_\text{loc}(B_I^+ \cup I)$ and there exists an $\epsilon = \epsilon(r) > 0$ such that whenever $\|\nabla \phi\|_{L^2(B_I^+)} \leq \epsilon$ then
\[
\|\nabla \psi\|_{L^r(B_I^+)} \leq C\|\psi\|_{L^4(B_I^+)}. \tag{4.1}
\]

Assuming the claim (and shrinking the domain slightly), for some $1 < p < 2$ we simultaneously have $f \in L^p(B_I^+)$ and $\mathcal{G} \in W^{1, p}_\partial(I)$. Thus, applying Theorem 1.2 we can conclude that $\phi \in W^{2, p}_\text{loc}(B_I^+ \cup I)$ with an appropriate estimate.

Now, the coupled system we are looking at is
\[
\phi^i = -\Gamma^i_{jk}(\phi) \partial_{\psi^j} \phi^k \cdot \psi^k, \quad i = 1, 2, \ldots, d, \tag{4.1}
\]
\[
\mathbf{B}_R^\psi \psi = 0 \quad \text{on } I. \tag{4.2}
\]

We now assume the following:

**Theorem 4.6.** Let $k \in \mathbb{N}_0$, $1 < p < \infty$, $U \subset \mathbb{R}^2$ any open set with $T \subset \partial U$ a smooth boundary portion. Suppose $\psi = \left(\begin{array}{c} \psi_+ \\ \psi_- \end{array}\right) \in W^{1, p}(U, C^2 \otimes \mathbb{R}^d)$ solves the following boundary value problem:
\[
\mathcal{D} \psi = F \in W^{k, p}(U) \quad \text{in } U
\]
and
\[
\mathbf{B}_R^\psi \psi = 0 \quad \text{on } T \subset \partial U \quad \iff \quad \psi_+ = \mp R \psi_-, \quad \text{on } T \subset \partial U,
\]
where $R$ is as in (1.6). Then for any $V \subset \subset U \cup T$, $\psi \in W^{k+1, p}(V)$ and there exists some $C = C(p, V, T) > 0$ such that
\[
\|\psi\|_{W^{k+1, p}(V)} \leq C(\|F\|_{W^{k, p}(U)} + \|\psi\|_{L^p(U)}).
\]

**Remark 4.7.** We point out here that the chirality boundary condition for $\mathcal{D}$ is (morally speaking) a traditional boundary condition for the Cauchy-Riemann operator $\overline{\partial}$. It is easy to check (and we will do so) that we can frame this system as a coupled system of $\overline{\partial}$ equations with a vanishing imaginary (or real) part on the boundary. Thus this theorem can be thought of as classical.

For us we have that $U = B_I^+$, $T = I$ and given the discussion in section 3.2 - see (3.18) - our spinor $\psi$ satisfies the conditions of the theorem.

A bootstrapping argument by repeatedly applying Theorem 4.6 with the results from appendix E finishes the proof of Theorem 1.6. \hfill \square
Proof of Theorem 4.6: We can de-couple the PDE, letting \( F = \begin{pmatrix} F_+ \\ F_- \end{pmatrix} \) we have that (see (3.17))
\[
\partial \left( \begin{array}{c} \psi_+ \\ \psi_- \end{array} \right) = 2i \left( \begin{array}{c} \partial \psi_- \\ \partial \psi_+ \end{array} \right).
\]
Therefore
\[
\bar{\partial}(\psi_+) = -\frac{i}{2} F_- \quad \text{and} \quad \bar{\partial}(\psi_-) = \frac{i}{2} F_+.
\]
in \( U \) with
\[
\psi_+ \pm R \psi_- = 0 \quad \text{on} \quad \partial U.
\]

Letting
\[
h_1 := \psi_+ \pm R \psi_- \quad \text{and} \quad h_2 := \psi_+ \mp R \psi_-,
\]
we have that \( h_j \) solve
\[
\bar{\partial}(h_1) = -\frac{i}{2} (F_- \mp R F_+) \quad \text{in} \quad U, \quad \text{Re}(h_1) = 0 \quad \text{on} \quad T \subset \partial U
\]
and
\[
\bar{\partial}(h_2) = -\frac{i}{2} (F_- \pm R F_+) \quad \text{in} \quad U, \quad \text{Im}(h_2) = 0 \quad \text{on} \quad T \subset \partial U.
\]

Now applying Theorem E.3 and noting that \( \psi = \frac{1}{2} \left( h_1 + h_2 \pm R (h_1 - h_2) \right) \) we have completed the proof of Theorem 4.6. \( \square \)

Proof of the Claim:

We prove the claim via the following:

Theorem 4.8. Let \( B_1^+ \subset \mathbb{R}^2 \) and suppose \( \psi = \left( \begin{array}{c} \psi_+ \\ \psi_- \end{array} \right) \in W^{1,1}(B_1^+, C^2 \otimes \mathbb{R}^d) \) solves the following boundary value problem:
\[
\partial \psi = \Gamma \gamma_\alpha \cdot \psi \quad \text{in} \quad B_1^+
\]
and
\[
\mathbf{B}^{\frac{1}{2}} \psi = 0 \quad \text{on} \quad I \iff \psi_+ = \mp R \psi_- \quad \text{on} \quad I
\]
for \( \Gamma \in L^2(B_1^+, gl(d) \otimes \wedge^1 \mathbb{R}^2) \) and \( R \) is as in (1.6). Then for any \( 2 \leq q < \infty, \psi \in W^{1, \frac{2q}{q}}_{\text{loc}}(B_1^+ \cup I) \) and there exist \( \epsilon = \epsilon(q) > 0 \) and \( C = C(q) > 0 \) such that if
\[
\|\Gamma\|_{L^2(B_1^+)} \leq \epsilon
\]
then
\[
\|
\nabla \psi\|_{L^{2q}(B_1^+)} + \|\psi\|_{L^q(B_1^+)} \leq C \|
\psi\|_{L^4(B_1^+)}. \]

Clearly setting \( (\Gamma_1^j)_\alpha = -\Gamma_{jk}^i (\phi) \delta^i_\alpha \) we see that since our spinor solves (4.1) and (4.2) we have proved the claim. \( \square \)

Proof of Theorem 4.8: First of all note that using (3.16) and (3.17), for \( x \in B_1^+ \) we have
\[
\bar{\partial} \psi(x) = 2i \left( \begin{array}{c} \frac{\partial \psi_+}{\partial x^j}(x) \\ \frac{\partial \psi_-}{\partial x^j}(x) \end{array} \right)
\]
\[
= \left[ \Gamma_1(x) \left( \begin{array}{cc} 0 & i \\ i & 0 \end{array} \right) + \Gamma_2(x) \left( \begin{array}{cc} 0 & 1 \\ -1 & 0 \end{array} \right) \right] \left( \begin{array}{c} \psi_+(x) \\ \psi_-(x) \end{array} \right)
\]
\[
= \left( \frac{i \Gamma_1(x) + \Gamma_2(x)}{2} \right) \psi_-(x) \psi_+(x)
\]
\[
= \left( \frac{i \Gamma_1(x) - \Gamma_2(x)}{2} \right) \psi_+(x) \psi_-(x).
\]
Extend the quantities arising in the theorem as follows:

\[
\psi_E(x) := \begin{cases} 
    \left( \begin{array}{c}
        \psi_+(x) \\
        \psi_-(x)
    \end{array} \right) & \text{if } x \in B_1^+ \\
    \mp \left( \begin{array}{c}
        R\psi_-(\rho(x)) \\
        R\psi_+(\rho(x))
    \end{array} \right) & \text{if } x \in B_1^-,
\end{cases}
\]

\[
\Gamma_E(x) := \begin{cases} 
    \Gamma(x) & \text{if } x \in B_1^+ \\
    R\rho^*\Gamma(x)R & \text{if } x \in B_1^-.
\end{cases}
\]

We leave it to the reader to check that \(\psi_E \in W^{1,1}(B_1)\) so we only have to check that \(\psi_E\) solves the correct PDE on the lower half ball. Take \(x \in B_1^-\) and check using (3.16) and (3.17) that

\[
\varphi \psi_E(x) = \mp 2i \left( \frac{R\phi_+^*(\rho(x))}{R\phi_+^*(\rho(x))} \right) \left( \frac{R[\Gamma_1(\rho(x)) - \Gamma_2(\rho(x))]\psi_+(\rho(x))}{R[\Gamma_1(\rho(x)) + \Gamma_2(\rho(x))]\psi_-(\rho(x))} \right)
\]

\[
= \mp \left( \begin{array}{cc}
    0 & i \\
    i & 0
\end{array} \right) - R\Gamma_2(\rho(x))R \left( \begin{array}{cc}
    0 & 1 \\
    -1 & 0
\end{array} \right) \left( \mp R\psi_-(\rho(x)) \right) \\
= \Gamma_E(x)\alpha_\gamma \cdot \psi_E(x)
\]

where we have used that \(\Gamma = \Gamma_1 dx_1 + \Gamma_2 dx_2\) so that

\[
R\rho^*\Gamma(x)R = R\Gamma_1(\rho(x))Rdx_1 - R\Gamma_2(\rho(x))Rdx_2.
\]

Therefore we have

\[
\varphi \psi_E = (\Gamma_E)\alpha_\gamma \cdot \psi_E \quad \text{in } B_1
\]

at which point Theorem 4.1 finishes the proof. \(\square\)

## A Hardy Spaces

Pick \(\phi \in C_c^\infty(B_1)\) such that \(\int \phi = 1\) and let \(\phi_t(x) = t^{-m} \phi(t^2)\). For a distribution \(f\) we say \(f\) lies in the Hardy space \(H^1(\mathbb{R}^m)\) if \(f_\ast \in L^1(\mathbb{R}^m)\) where

\[
f_\ast(x) = \sup_{r > 0} |(\phi_t \ast f)(x)|
\]

with norm \(\|f\|_{H^1(\mathbb{R}^m)} = \|f_\ast\|_{L^1(\mathbb{R}^m)}\). Clearly we have the continuous embedding

\[
H^1(\mathbb{R}^m) \hookrightarrow L^1(\mathbb{R}^m).
\]

The dual space of \(H^1(\mathbb{R}^m)\) is \(BMO(\mathbb{R}^m)\) where

\[
BMO := \{ g \in L^1_{loc}(\mathbb{R}^m) : \sup_{r > 0} \int_{B_r(x)} |g - g_{r,x}| < \infty \}
\]

(see [10]). We will also consider a local \(BMO\) space for \(E \subset \mathbb{R}^m\),

\[
BMO(E) := \{ g \in L^1_{loc}(E) : \sup_{r > 0} \int_{B_r(x) \cap E} |g - g_{r,x}| < \infty \}.
\]

Where \(g_{r,x} = \int_{B_r(x) \cap E} g\). We note the following extension theorem for \(BMO\):
Theorem A.1. The unit ball \( B_1 \subset \mathbb{R}^m \) is an extension domain for \( BMO \). In other words given \( u \in BMO(B_1) \) there exists \( \tilde{u} \in BMO(\mathbb{R}^m) \) such that

\[
\| \tilde{u} \|_{BMO} \leq C \| u \|_{BMO(B_1)}
\]

and \( u = \tilde{u} \) almost everywhere in \( B_1 \).

See [28] for a proof.

Related to \( \mathcal{H}^1 \) is the so-called local Hardy space \( h^1 \) defined to be those functions for which

\[
f(x) = \sup_{0 < t < 1} |(\phi_t * f)(x)| \in L^1(\mathbb{R}^m)
\]

with corresponding norm. Again we clearly have the continuous embedding \( h^1(\mathbb{R}^m) \hookrightarrow L^1(\mathbb{R}^m) \).

The space \( \mathcal{H}^1 \) is not stable by multiplication of smooth functions since \( f \in \mathcal{H} \) implies \( \int f = 0 \). However for the local Hardy space \( h^1 \), as long as the multiplier function is sufficiently regular then we have stability. For instance if \( h \in h^1 \) and \( g \in C_0^\infty, \gamma \), then \( gh \in h^1 \) and

\[
\| gh \|_{h^1} \leq C(\gamma) \| g \|_{C_0^\infty, \gamma} \| h \|_{h^1}.
\]

We also state here an important result of Coiffman et al., [8] which states that (in particular) given two one forms \( D, E \in L^2(\mathbb{R}^m, \bigwedge^1 \mathbb{R}^m) \) such that \( dE = 0 \) and \( d^* D = 0 \) weakly, then \( \langle E, D \rangle \in \mathcal{H}^1(\mathbb{R}^m) \) with

\[
\| \langle E, D \rangle \|_{\mathcal{H}^1(\mathbb{R}^m)} \leq C \| E \|_{L^2(\mathbb{R}^m)} \| D \|_{L^2(\mathbb{R}^m)}.
\]

**B Morrey Spaces**

We introduce the Morrey spaces \( M^{p, \beta}(E) \) for \( 1 \leq p < \infty \) and \( 0 \leq \beta \leq m \) \((E \subset \mathbb{R}^m)\). We say that \( g \in M^{p, \beta}(E) \) if

\[
M_\beta[g^p](x) := \sup_{r > 0} r^{-\beta} \int_{B_r(x) \cap E} |g|^p \in L^\infty
\]

with norm (which makes \( M^{p, \beta} \) a Banach space)

\[
\| g \|_{M^{p, \beta}(E)} = \| M_\beta[g^p] \|_{L^\infty(E)}.
\]

We note the following extension theorem for Sobolev-Morrey spaces:

**Theorem B.1.** The unit ball \( B_1 \subset \mathbb{R}^m \) is an extension domain for \( M_1^{p, \beta} \). Given \( v \in M_1^{p, \beta}(B_1) \) there exists \( \tilde{v} \in M_1^{p, \beta}(\mathbb{R}^m) \) such that

\[
\| \tilde{v} \|_{M^{p, \beta}} + \| \nabla \tilde{v} \|_{M^{p, \beta}} \leq C(\| v \|_{M_1^{p, \beta}(B_1)} + \| \nabla v \|_{M_1^{p, \beta}(B_1)})
\]

and \( v = \tilde{v} \) almost everywhere.

We could not find a proof of this theorem, however it follows easily by standard techniques for extension theorems. In general it should remain true for any domain \( U \) with \( \partial U \) as above but \( \phi \) must be Lipschitz. A useful reference in proving such a theorem is [11].
We also note that if $\int_{B_1} v = 0$ then
\[ \|\nabla v\|_{MP,\beta} \leq C([v]_{C^{p,\beta}(B_1)} + \|\nabla v\|_{MP,\beta}(B_1)) \leq C\|\nabla v\|_{MP,\beta}(B_1) \]
where $C^{p,\beta}$ is the Campanato space - see [12].

## C Hodge decompositions

We denote here the Hodge star operator on $k$-forms by $*$ and the related exterior derivative, $d$ and divergence operator $d^*$-which is the formal adjoint of the exterior derivative:
\[ d^* : \Gamma(\wedge^k\mathbb{R}^m) \to \Gamma(\wedge^{k-1}\mathbb{R}^m) \]
satisfies
\[ d^* v = (-1)^{n(k+1)+1} \ast d \ast v \]
for $v \in \Gamma(\wedge^k\mathbb{R}^m)$. There is a natural point-wise inner product for $k$-forms given by $\langle \omega^1, \omega^2 \rangle = \ast(\omega^1 \wedge \ast \omega^2)$ and a natural pairing given by $\langle \omega^1, \omega^2 \rangle = \int \ast(\omega^1, \omega^2)$. Of course for $\omega_1 \in L^p$ and $\omega_2 \in L^p$, however when $p = 2$ this is simply an inner product.

Our main reference here is [21] where we can find all of the results stated below, in particular we require the following ([21, Theorem 5.4 and Corollary 5.6]). We note that $W^{1,p}_N$ (resp $W^{1,p}_T$) is used to denote a Sobolev space of forms whose normal (tangential) parts vanish at the boundary. Moreover for functions (or zero-forms) $f$, we have $f = f_T$ and for top forms $g$ we have $g_N = g$. We denote by $H_N$ (resp $H_T$) the space of harmonic forms whose normal (tangential) parts at the boundary vanish and are in $L^p$.

**Theorem C.1.** Let $1 < p < \infty$ and $B_1 \subset \mathbb{R}^m$.

\[
L^p(B_1, \wedge^1 \mathbb{R}^m) = dW^{1,p}_0(B_1) \oplus d^*W^{1,p}_N(B_1, \wedge^2 \mathbb{R}^m) \oplus H^p(B_1, \wedge^1 \mathbb{R}^m) \quad \text{(C.1)}
\]

\[
= dW^{1,p}_0(B_1) \oplus d^*W^{1,p}_T(B_1, \wedge^2 \mathbb{R}^m) \oplus H^p_T(B_1, \wedge^1 \mathbb{R}^m) \quad \text{(C.2)}
\]

\[
= dW^{1,p}_N(B_1) \oplus d^*W^{1,p}_T(B_1, \wedge^2 \mathbb{R}^m) \oplus H^p_T(B_1, \wedge^1 \mathbb{R}^m). \quad \text{(C.3)}
\]

In other words if $\omega \in L^p(B_1, \wedge^1 \mathbb{R}^m)$ then there exist $a \in W^{1,p}_N(B_1)$, $b \in W^{1,p}(B_1, \wedge^2 \mathbb{R}^m)$ and $h \in H^p(B_1, \wedge^1 \mathbb{R}^m)$ satisfying one of the three conditions appearing above with
\[
\omega = da + d^*b + h.
\]

Moreover they are unique under the following conditions (respectfully as the decompositions appear in (C.1), (C.2) and (C.3))

\[
b \in dW^{1,p}(B_1, \wedge^1 \mathbb{R}^m)
\]

\[
b \in dW^{1,p}_N(B_1, \wedge^1 \mathbb{R}^m)
\]

\[
a \in d^*W^{1,p}_N(B_1, \wedge^1 \mathbb{R}^m) \text{ and } b \in dW^{1,p}(B_1, \wedge^1 \mathbb{R}^m).
\]

and we have the following estimate
\[
\|a\|_{W^{1,p}(B_1)} + \|b\|_{W^{1,p}(B_1)} + \|h\|_{L^p(B_1)} \leq C(p)\|\omega\|_{L^p(B_1)}.
\]

We note separately that when $p = 2$ we actually have
\[
\|da\|_{L^2(B_1)}^2 + \|d^*b\|_{L^2(B_1)}^2 + \|h\|_{L^2(B_1)}^2 = \|\omega\|_{L^2(B_1)}^2.
\]
We could define \( W_{1,p}^1(B_1, \wedge^k \mathbb{R}^m) \) in a trace sense or equivalently for any smooth \( k - 1 \) form \( \nu \) we have \( (\omega, d\nu) = (d^* \omega, \nu) \) when \( \omega \in W_{1,2}^1(B_1, \wedge^k \mathbb{R}^m) \).

Otherwise we have the more general formula for smooth \( k \) and \( k - 1 \) forms respectively (which follows from Stoke’s theorem)

\[
(\omega, d\nu) = (d^* \omega, \nu) + \int_{\partial} \nu_T \wedge \ast \omega_N
\]

where \( T \) and \( N \) denote the tangential and normal components. (The latter holds for any appropriate Sobolev forms by approximation). Note we could define \( W_{1,p}^1(B_1, \wedge^k \mathbb{R}^m) \) in either way also. We use the following fact which follows by approximation: For \( a \in W_{1,p}^1(B_1, \wedge^{k-1} \mathbb{R}^n) \), \( b \in W_{1,p'}^1(B_1, \wedge^k \mathbb{R}^n) \) we have

\[
(d a, d^* b) = 0
\]

if either \( a_T = 0 \) or \( b_N = 0 \) (of course \( \frac{1}{p} + \frac{1}{p'} = 1 \) here).

## D Coulomb gauge

Here we state the result we require in order to find a Coulomb gauge in the Morrey space setting. A proof of this theorem can be found in [30]

**Theorem D.1.** Let \( \Omega \in M^{2,m-2}(B_1, so(n) \otimes \wedge^1 \mathbb{R}^m) \), then there exists an \( \epsilon = \epsilon(m,n) > 0 \) such that whenever

\[
\| \Omega \|_{M^{2,m-2}(B_1)} \leq \epsilon
\]

then we can find maps \( P \in W^{1,2}(B_1, SO(n)) \) and \( \eta \in W_{0}^{1,2}(B_1, so(n) \otimes \wedge^2 \mathbb{R}^m) \) such that

\[
P^{-1} dP + P^{-1} \Omega = d^* \eta
\]

and

\[
d \eta = 0.
\]

Moreover there exists \( C = C(m,n) > 0 \) such that

\[
\| \nabla P \|_{M^{2,m-2}(B_1)} + \| \nabla \eta \|_{M^{2,m-2}(B_1)} \leq C \| \Omega \|_{M^{2,m-2}(B_1)}.
\]

## E Classical boundary value estimates

Here we recall results about boundary value problems for the Laplacian and the Cauchy-Riemann operator, we refer the reader to [40, 2] for background material.

The proofs of the following results follow from the classical theorems after applying suitable cut-off function arguments.

For all of the theorems below \( U \subset \mathbb{R}^m \) is any open domain and \( T \subset \partial U \) is a smooth boundary portion.

**Theorem E.1.** Let \( k \in \mathbb{N}_0 \) and \( 1 < p < \infty \). Suppose that \( u \in W^{1,p} \) weakly solves

\[
-\Delta u = f \in W^{k,p}(U)
\]

and

\[
u = 0 \quad \text{on } T
\]
then for any \( V \subset \subset U \cup T, u \in W^{k+2,p}(V) \) and there exists some \( C = C(p, k, V, T) > 0 \) such that
\[
\|u\|_{W^{k+2,p}(V)} \leq C(\|f\|_{W^{k,p}(U)} + \|u\|_{L^p(U)}).
\]

**Theorem E.2.** Let \( k \in \mathbb{N}_0 \) and \( 1 < p < \infty \). Suppose that \( u \in W^{1,p} \) weakly solves
\[
-\Delta u = f \in W^{k,p}(U)
\]
and
\[
\frac{\partial u}{\partial n} = g \in W^{k+1,p}_\partial(T)
\]
then for any \( V \subset \subset U \cup T, u \in W^{k+2,p}(V) \) and there exists some \( C = C(p, k, V, T) > 0 \) such that
\[
\|u\|_{W^{k+2,p}(V)} \leq C(\|f\|_{W^{k,p}(U)} + \|g\|_{W^{k+1,p}_\partial(T)} + \|u\|_{L^p(U)}).
\]

We also recall the analogue for the Cauchy-Riemann operator in \( \mathbb{C} \).

**Theorem E.3.** Let \( U \subset \mathbb{C} \) be any domain and \( T \subset \partial U \) a smooth boundary portion, \( k \in \mathbb{N}_0 \) and \( 1 < p < \infty \). Suppose that \( h \in W^{1,p} \) solves
\[
\overline{\partial} h = f \in W^{k,p}(U)
\]
and
\[
Re(h) = 0 \text{ or } Im(h) = 0 \text{ on } T
\]
then for any \( V \subset \subset U \cup T, h \in W^{k+1,p}(V) \) and there exists some \( C = C(p, k, V, T) > 0 \) such that
\[
\|h\|_{W^{k+1,p}(V)} \leq C(\|f\|_{W^{k,p}(U)} + \|h\|_{L^p(U)}).
\]
