Abstract: Surface charges of a $p$-form theory on the boundary of an AdS$_{d+1}$ spacetime are computed. Counter-terms on the boundary produce divergent corner-terms which holographically renormalize the symplectic form. Different choices of boundary conditions lead to various expressions for the charges and the associated fluxes. With the usual standard AdS boundary conditions, there are conserved zero-mode charges. Moreover, we explore two leaky boundary conditions which admit an infinite number of charges forming an Abelian algebra and non-vanishing flux. Finally, we discuss magnetic $p$-form charges and electric/magnetic duality.
1 Introduction

The relation between asymptotic symmetries, memory effects and soft theorems has provoked considerable progress in understanding the IR properties of field theories in the asymptotically flat spacetimes [1–4]. See also [5] and the references therein. Similar to global symmetries, large gauge transformations/diffeomorphisms lead to Ward identities in the quantum theory, as can be seen in the path integral formulation [6]. Physical boundary conditions for the gauge field or the metric can be assigned such that the equivalence of Ward identities with soft theorems hold. For instance, subleading soft graviton theorems in four dimensional asymptotically flat space, suggest an extension of the standard BMS group to include superrotations [7–9]. Identifying the correct set of boundary conditions that describe localized systems is a key step in understanding holography in asymptotically flat spacetimes, as it specifies the symmetries of the putative CFT in the semi-classical regime [10–13].

An insightful approach to holography in asymptotically flat spacetimes is to embed these spaces in a larger Anti-de Sitter space (AdS) [14–16]. In particular, the relation between boundary CFT Ward identities and bulk soft theorems in the flat (i.e. large AdS radius) limit is explored in [17, 18]. A natural expectation is to find appropriate boundary conditions for AdS theories which reduce to the standard asymptotically flat boundary conditions in large AdS radius limit. The standard treatment of AdS_{d+1} Einstein gravity is to fix a conformal class of metrics on the boundary, for which the asymptotic symmetry group is isomorphic to the d-dimensional conformal group. Otherwise, by fixing Neumann or mixed boundary conditions, the boundary metric is allowed to fluctuate which translates into energy flux on the boundary [19, 20]. In AdS_4 Compère et al found that by choosing a foliation and a measure on the boundary manifold, the asymptotic symmetry group is the so-called Λ-BMS group [21, 22] which reduces to the centerless BMS_4 in the large AdS radius limit. See also [23] for extension to higher dimensions.

In a previous study [24], we considered Maxwell theory in Anti-de Sitter space and constructed the infinite-dimensional asymptotic symmetry algebra. To analyze this problem we adopted hyperbolic slicing of the AdS space. The phase space consisted of charged particles moving freely and scattering off at the origin of the hyperbolic coordinate system. In this special system, we can treat the boundary like the spatial infinity of Minkowski space as pointed out in [18] and henceforth we expect charge conservation. In this paper, we generalize the boundary conditions to include generic solutions to Maxwell’s field equations including radiation that reach the boundary, as well as generalization to p-form theories.

Higher form gauge fields are natural objects of study from a supergravity and string theory perspectives [25, 26]. p-brane solutions couple to and source the p+1-form gauge fields. p-branes and likewise p+1-forms, may be residing on various background geometries, such as flat or AdS backgrounds. The main objective of this paper is a near-boundary analysis of p-form gauge fields and constructing the surface charges associated with residual gauge transformations.

A clear and thorough treatment of field equations and Cauchy development for scalar theory, Maxwell theory and linearized gravity in d + 1 dimensional Anti-de Sitter space is performed by Ishibashi and Wald [27]. For Maxwell theory, that involves a decomposition of gauge field components into scalar and vector modes with respect to rotation group. Here we first generalize their analysis to a (p + 1)-form gauge field, for which the components can be expanded in terms of p-form and p+1-form spherical harmonics on the sphere S^{d−1}. These two
sets differ in their asymptotic behavior. We discuss normalizability of these modes in different dimensions.

In Lorentzian AdS, non-normalizable modes are fixed as background fields upon which the normalizable modes fluctuate \[28, 29\]. For some \(p, d\) values both bulk modes become normalizable \[30\], as we specify for different components of \(p\)-form fields. In our case, non-normalizable modes are those which make the symplectic form divergent. However, the symplectic form is modified when counter-terms are added on the boundary. Subtracting the divergences in the on-shell action is provided by local Lagrangians defined on the AdS boundary \[31, 32\]. Variation of the counter-terms produce total divergence terms, which are known as corner terms. These divergent contributions modify the symplectic form of the theory and make it finite \[19, 33, 34\]. We will exhibit the counter-term for \(p\)-form theory and construct the renormalized symplectic form, which guarantees finiteness of surface charges.

The residual gauge transformations after fixing the radial gauge have finite surface charges that follow from the renormalized symplectic structure. We derive the charge expression without imposing boundary conditions, and in particular allow finite gauge transformations on the boundary. For a Maxwell field this amounts to defining the Dirichlet condition as

\[
\delta F^{(0)}|_{\mathcal{F}} = 0
\]

(instead of the usual condition \(\delta A^{(0)}|_{\mathcal{F}} = 0\)). The generalized boundary condition that leads to this kind of constructions is in general leaky: one can not demand conservation and also infinite asymptotic symmetry at the same time. Thus, the flux on AdS boundary is non-vanishing except for the \(U(1)\) electric charge. Addition of boundary terms to the action leads to different charge expressions and different fluxes with no preferred criterion for choosing one. We examine two cases of boundary conditions with flux and derive the charge expressions for the boundary gauge mode (sketched in table 2).

As it turns out, conservation of the charges is closely related to the existence of an energy functional on the solution space. The reason is that addition of the boundary gauge transformations deforms the expression for the energy by a surface term and spoils its integrability. We discuss specific configurations with conserved charges and an integrable energy functional.

This paper is organized as follows. In section 2, the asymptotic behavior of \(p\)-form fields and their norms on Anti-de Sitter space is discussed. In section 3, we explain the renormalization procedure for the symplectic form upon which the later discussion is built. In section 4, we demonstrate how different charge expressions fail to be conserved and identify the conservative backgrounds. Section 5 is devoted to electric/magnetic duality as a symmetry of the \(p\)-form action and its relation to boundary conditions and magnetic charges (see also \[35\]). Finally, section 6 discusses non-integrability of energy on the phase space.

**Conventions and Notation.** We will use capital Latin indices \(I, J, K\) for denoting the coordinates of the \(d+1\)-space. We decompose the spacetime to 2-dimensional radial and time direction denoted by \(x^a \equiv \{t, r\}\) and the rest \(n = d-1\)-dimensional sphere denoted by \(z^i\). The coordinates on the boundary is also denoted by \(x^\mu \equiv \{t, z^i\}\).

## 2 The asymptotic behaviour of gauge field in AdS, normalizable modes

In this section, we review the asymptotic behaviour of \(p + 1\)-from gauge field on \(\text{AdS}_{d+1}\) based on the Ishibashi-Wald work \[27\]. We start by decomposition of the gauge field in terms of exact
and co-exact forms on the sphere and define two gauge invariant functions out of them. Then we write the symplectic from in terms of these functions. At last, we identify the normalizable modes defined as modes that keep the symplectic form finite.

2.1 Falloff conditions and equations of motions

The action is

\[ S = \frac{-1}{2(p+2)!} \int_M \sqrt{g} F_{I^2} \omega, \quad F_{I^2} = (p+2) \partial_I A_{1 \ldots I_{p+2}} \]  \tag{2.1}

where \( M \) is AdS spacetime and we work in global coordinates

\[ ds^2 = \frac{1}{\sin^2 x} \left[ -dt^2 + dx^2 + \cos^2 x d\Omega_d^2 \right] = -(r^2 + 1) dt^2 + \frac{dr^2}{r^2 + 1} + r^2 q_{ij} (z) dz^i dz^j \]  \tag{2.2}

where \( r = \cot x \) and the conformal boundary is at \( x = 0 \). \( q_{ij} (z) \) is the round unit sphere metric on of \( S^n \). The metric on the conformal boundary, \( R \times S^n \) is set as

\[ h_{\mu \nu} dx^\mu dx^\nu = -dt^2 + q_{ij} (z) dz^i dz^j. \]  \tag{2.3}

Given a radial coordinate \( r \) in AdS, The equation of motion \( \nabla_2 F_{I^2} I^{2p} = 0 \) breaks into two sets

\[ \nabla_2 F_{I^2} I^{2p} = \begin{cases} 0 & \text{Constraints}, \quad \text{(2.4)} \\ 0 & \text{Dynamical}. \quad \text{(2.5)} \end{cases} \]

Eq. (2.4) can be interpreted as the constraints on the boundary of AdS and eq. (2.5) determines the bulk fields in terms of their values on the boundary. The existence of the constraints on the boundary is due to the gauge structure of the theory.

We exhibit field equation in terms of gauge invariant variables made out of the gauge field and its derivatives, following the analysis of Ishibashi and Wald [27]. For this purpose it is convenient to define an \( AdS_2 \) metric \( g_{ab} \) to write the spacetime metric as

\[ ds^2 = g_{ab} (x) dy^a dy^b + r^2 q_{ij} (z) dz^i dz^j \quad 0 < x \leq \frac{\pi}{2}. \]  \tag{2.6}

We start by decomposing different components of the gauge field in terms of exact and co-exact forms on the \( n \)-sphere.

\[ A_{I^2} = \sum_k \left( \psi^{(k)} T^{(k)}_{I^2} + f^{(k)} dT^{(k)}_{I^2} \right) \]  \tag{2.7a}

\[ A_{aI^p} = \sum_k \left( f^{(k)} T^{(k)}_{I^p} + g^{(k)} T^{(k)}_{I^p-1} \right) \]  \tag{2.7b}

\[ A_{abI^{p-1}} = \sum_k \left( f^{(k)} T^{(k)}_{I^p} + g^{(k)} T^{(k)}_{I^p-2} \right) \]  \tag{2.7c}

where \( T^{(k)}_{I^p} \) is a \( p \)-form spherical harmonic on the \( S^n \) and \( d \) is the exterior derivative on the sphere. Note that \( \psi^{(k)} \) exists when \( n > p + 1 \). A \( p \)-form spherical harmonic is a divergenceless \( p \)-form on \( n \)-sphere \( D^I T_{j_2 \ldots i_p} = 0 \) that diagonalizes the Laplace-Beltrami operator \( \Delta = dd^1 + d^1 d \) as

\[ \Delta T^{(k)}_{I^p} = k^2 T^{(k)}_{I^p}, \quad k^2 = (k + d - 2) + q(d - q - 2) \]  \tag{2.9}

\[^1d^1 = \ast d\ast \text{ is the adjoint of exterior derivative } d \text{ with respect to the standard inner product of } p \text{-forms on sphere } \]

\[ \langle d\alpha, \beta \rangle = \langle \alpha, d^1 \beta \rangle. \]  \tag{2.8}
Harmonics with different $k$ are orthogonal. To fix the normalization, let us revert the implicit index $m$ that labels different $p$-form spherical harmonics $T^{(k,m)}$ with the same eigenvalue $k_q^2$, and demand that

$$\int_{S^n} \sqrt{q} T^{(k,m)}_{(k,m')} T^{(k',m')}_{(k,m)} = p! \delta_{k,k'} \delta_{m,m'} \quad (2.10)$$

We will generally suppress the index $m$ to reduce clutter.

Note that $n > p$. The field strength tensor is

$$F_{ab} = \hat{\nabla}_a A_{b} - \hat{\nabla}_b A_{a} + d A_{ab}^{-1} \quad (2.11a)$$

$$F_{a} = \hat{\nabla}_a A_{p+1} - d A_{a} \quad (2.11b)$$

$$F_{p+2} = d A_{p+2} \quad (2.11c)$$

where $\hat{\nabla}_a$ is the covariant derivative of the metric $g_{ab}$ on AdS. We call the coefficients of $T^{(k)}_{(k)}$, $p$-form components and the coefficients of $T^{(p+1)}_{(p+1)}$, $(p+1)$-form components drop from the constraint equations. Normally, the radial gauge is fixed. In contrast, different $p$-form components appearing in the gauge field are coupled by the constraint equations to give one independent $p$-form on the boundary after fixing the radial gauge $A_{r2p} = 0$. Now we solve field equations for $p$-form and $(p+1)$-form components separately.

$(p+1)$-form components

There exists only one $(p+1)$ component in the gauge field which is $\psi$. For this component we have

$$F_{ab} = 0, \quad F_{a} = \sum_k \hat{\nabla}_a \psi^{(k)} T^{(k)}_{(p+1)}, \quad F_{p+2} = \sum_k \psi^{(k)} d T^{(k)}_{(p+1)} \quad (2.12)$$

and the equations of motion take the form

$$r^{6+2p-2} \sum_k \hat{\nabla}_a \left( r^{d-4-2p} \hat{\nabla}_a \psi^{(k)} \right) - k_{p+1}^2 \psi^{(k)} = 0 \quad (2.13)$$

Equation (2.13) expands to

$$\frac{\partial^2 \psi^{(k)}}{\partial t^2} = \frac{1}{r^{d-3-2p}} \frac{\partial}{\partial x} \left( r^{d-3-2p} \frac{\partial \psi^{(k)}}{\partial x} \right) - \frac{(1 + r^2)k_{p+1}^2}{r^2} \psi^{(k)} \quad (2.14)$$

By re-scaling $\psi^{(k)} = r^{(d-2p-3)/2} \tilde{\psi}^{(k)}$ the differential equation simplifies to

$$\frac{\partial^2 \tilde{\psi}^{(k)}}{\partial t^2} = \left( \frac{\partial^2}{\partial x^2} - \frac{\nu^2 - 1/4}{\sin^2 x} - \frac{\sigma^2 - 1/4}{\cos^2 x} \right) \tilde{\psi}^{(k)} \quad (2.15)$$

with

$$\nu_1 = \frac{1}{2} |n_p - 1|, \quad \sigma = k + \frac{d - 2}{2} \quad (2.16)$$

where we define $n_p = n - 2p$. In the form (2.15), the number of normalizable modes is simple to decide (basically, depending on the sign of $\nu_1 - 1$). The special cases $p = 0$ (vector part of Maxwell theory) and $p = -1$ (scalar field) are previously studied [27].

We are mainly concerned with the asymptotic behavior of the solutions. Assuming a fall-off of the form $\psi^{(k)} \sim r^{\lambda} \psi$, (2.14) implies

$$(n_p - 1 + \lambda) \lambda \psi = 0 \quad (2.17)$$

The two solutions for $\lambda = 0$ and $\lambda = 1 - n_p$. When $n_p = 1$ however we must add a logarithmic term at the leading order.
\textbf{\textit{p-form components}}

The non-vanishing components of the field strength arising from \textit{p}-form harmonics are

\[ \mathcal{F}_{ab}^p = \sum_k \left( \nabla_a f^{(k)}_b - \nabla_b f^{(k)}_a \right) \mathbb{T}^{(k)}_{ab} \]  \hspace{1cm} (2.18a)

\[ \mathcal{F}_{a\bar{p}}^{p+1} = \sum_k \left( \nabla_a f^{(k)} - f^{(k)}_a \right) d \mathbb{T}^{(k)}_{a\bar{p}} \]  \hspace{1cm} (2.18b)

\[ \mathcal{F}_{a\bar{p}}^{p+2} = 0. \]  \hspace{1cm} (2.18c)

From the \( \mathbb{T}^{p+1} \) components of equation of motions \( \nabla_I \mathcal{F}^{I\mathbb{T}^{p+1}} = 0 \) and from the fact that \( \mathcal{F}_{a\bar{p}}^{p+2} = 0 \) for the \( p \)-component case, we have \( \nabla_a (r^{d-1} \mathcal{F}^{a\mathbb{T}^{p+1}}) = 0 \). This leads us to define the scalars \( \phi^{(k)}(x^a) \),

\[ \mathcal{F}_{a\bar{p}}^{p+1} = r^{2p+3-d} \sum_k \epsilon_{ab} \nabla^b \phi^{(k)} d \mathbb{T}^{(k)}_{a\bar{p}} \]  \hspace{1cm} (2.19)

up to a constant shift \( \phi^{(k)} \rightarrow \phi^{(k)} + \text{const} \). So we have \( r^{2p+3-d} \epsilon_{ab} \nabla^b \phi^{(k)} = \nabla_a f^{(k)} - f^{(k)}_a \), which implies that \( 2 \nabla_{[a} f_{b]} = \epsilon_{ab} \nabla_c (r^{2p+3-d} \nabla^c \phi) \) and we can read \( \mathcal{F}_{a\bar{p}}^p \) in terms of \( \phi^{(k)} \),

\[ \mathcal{F}_{a\bar{p}}^p = \epsilon_{ab} \sum_k \nabla_c (r^{2p+3-d} \nabla^c \phi^{(k)}) \mathbb{T}^{(k)}_{a\bar{p}}. \]  \hspace{1cm} (2.20)

From the \( a\bar{p}^p \) components of (2.5) we have,

\[ \nabla_b \left( r^{d-2p-1} \nabla_a (r^{2p+3-d} \nabla^a \phi^{(k)}) - k_p^2 \phi^{(k)} \right) = 0. \]  \hspace{1cm} (2.21)

The equation then takes the form

\[ r^{d-2p-3} \nabla_a (r^{2p+3-d} \nabla^a \phi^{(k)}) - \phi^{(k)} k_p^2 \phi^{(k)} = \frac{c}{r^2}. \]  \hspace{1cm} (2.22)

Unless \( k_p^2 = 0 \), the constant \( c \) can be absorbed in \( \phi \) by constant shift\footnote{If \( k_p^2 = 0 \), the solutions is \( \mathcal{F}_{a\bar{p}}^p \approx \epsilon_{ab} \epsilon r^{-n_p} \mathbb{T}^{(0)}_{a\bar{p}} \).} and one obtains the useful relation

\[ \mathcal{F}_{a\bar{p}}^p \approx \epsilon_{ab} \sum_k k_p^2 \phi^{(k)} r^{-n_p} \mathbb{T}^{(k)}_{a\bar{p}}. \]  \hspace{1cm} (2.23)

Rewriting (2.22) as,

\[ \frac{\partial^2}{\partial t^2} \phi^{(k)} = \frac{1}{r^{2p+3-d}} \frac{\partial}{\partial x} \left( r^{2p+3-d} \frac{\partial}{\partial x} \phi^{(k)} \right) - \frac{k_p^2}{r^2} (1 + r^2) \phi^{(k)} \]  \hspace{1cm} (2.24)

and rescaling the field as \( \phi^{(k)} = r^{(3+2p-d)/2} \phi^{(k)} \) we arrive at the final form

\[ \frac{\partial^2}{\partial t^2} \phi^{(k)} = \left( \frac{\partial^2}{\partial x^2} - \frac{\nu_0^2}{\sin^2 x} - \frac{\sigma^2 - 1/4}{\cos^2 x} \right) \phi^{(k)} \]  \hspace{1cm} (2.25)

where \( \nu_0 = \frac{1}{2} |d - 2p - 4| \) and \( \sigma \) is given in (2.16). The particular case \( p = 0 \) (scalar part of Maxwell theory) was previously considered \cite{27}. By expanding (2.24) near the boundary and assuming the behavior \( \phi^{(k)} \sim r^{\lambda_0} \) we find

\[ (3 - n_p + \lambda_0) \lambda_0 = 0. \]  \hspace{1cm} (2.26)

As a result, we have two independent solutions with \( r^0 \) and \( r^{n_p-3} \) falloff behaviour at infinity. Again when \( n_p = 3 \) we need a logarithmic term at the leading order to have two independent solutions.
(p−1)- and (p−2)-form components

Assuming that only the coefficients of $T_{\nu-1}^{(k)}$ and $T_{\nu-2}^{(k)}$ in (2.7) are non-vanishing, the the field strength tensor is

$$F_{a \nu+1} = 0, \quad F_{\nu+2} = 0, \quad F_{ab} = \sum_k \left( \nabla_a g_b^{(k)} - \nabla_b g_a^{(k)} + f_{ab}^{(k)} \right) dT_{\nu-1}^{(k)}. \quad (2.27)$$

The equation of motion $D_j F^{j\nu-1} = 0$ implies $F_{ab} = 0$ for (p−1)-form sector. This is because there is no zero mode for the Laplace-Beltrami operator on p forms on $S^n$ topology if $p \neq 0, n$. Thus, p−1 forms do not appear in the on-shell field strength and we further conclude that $-\nabla_a g_b^{(k)} + \nabla_b g_a^{(k)} = f_{ab}^{(k)}$. For the (p−2)-form components, all the components of the field strength are identically vanishing.

**Degrees of freedom** The (p+1)-form gauge theory on $AdS_{d+1}$ has $(d-1)_{p+1}$ degrees of freedom [36]. This can be seen by enumerating the constraints in the Hamiltonian formulation. The (p+1)-form components are arbitrary divergenceless (p+1)-forms on the d−1-sphere, which we have expanded on the basis $T_{\nu+1}$. The total components of $T_{\nu+1}$ is $(d-1)_{p+1}$. The divergence-free condition $D^k T_{ji} = 0$ is a set of $(d-2)_p$ constraints. However, these are not independent as $D^k D^j T_{ji} - T_{ji} = 0$ identically. This reduces the number of constraints by $(d-2)_p$. This counting iterates as

$$\binom{d-1}{p+1} - \binom{d-2}{p} + \binom{d-2}{p-1} - \cdots - (-1)^{p+1} \binom{d-1}{0} = \binom{d-2}{p+1}. \quad (2.28)$$

Therefore, there are $(d-2)_{p+1}$ degrees of freedom in p+1-form components ($\psi$). Similar counting yields $(d-2)_p$ degrees of freedom for p-form components ($\phi$). For instance, 2-form theory on $AdS_5$ has two 2-form components and one 1-form component. The two numbers coincide only if $d = 2p + 3$ (i.e. $n_p = 2$).

**2.2 Normalizability**

There are different norms for field theories on AdS. The field configurations are *normalizable* if they have finite a norm, and *non-normalizable* otherwise. Normalizable modes have finite conserved energy as well. We define normalizability with the condition that the symplectic structure be finite with the asymptotic behaviour at hand.

In the radial gauge, the symplectic form is,

$$\Omega = \int_\Sigma \omega^t = \frac{1}{(p+1)!} \int_\Sigma \sqrt{g} \delta A_{p+1} \delta F_{p+1} = \frac{1}{(p+1)!} \int_\Sigma \sqrt{g}^{p+2} \delta F_{p+1} \delta A_{p+1} \quad (2.29)$$

where $\omega^t = \delta \theta^t$ and $\theta^t$ is the symplectic potential of the theory. In terms of gauge invariant variables $\psi$ and $\phi$ the symplectic form is

$$\Omega = \Omega^{(p)} + \Omega^{(p+1)} \quad (2.30)$$

where

$$\Omega^{(p)} = k_p^2 \int_\Sigma \frac{dr}{(r^2 + 1)} \delta \phi^{(k)} \delta \phi^{(k)} + k_p^2 \left( \delta \phi^{(k)} \delta f^{(k)} \right) \mid_\sigma \quad (2.31a)$$

$$\Omega^{(p+1)} = \int_\Sigma \frac{dr}{(r^2 + 1)} \delta \psi^{(k)} \delta \psi^{(k)} \quad (2.31b)$$

---

3In our convention, the $\sqrt{g}$ “factor” is absorbed in the definition of $\theta^t$ and $\omega^t$ to reduce clutter.
where the sum over $k$ is understood. Prior to gauge fixing, $f(k)$ can be shifted by arbitrary gauge transformations. Note that the appearance of the gauge mode is in the $p$-form sector and the $(p+1)$-form sector is free of such a mode. We will come back to this gauge part but we dismiss it for the moment. If $\nu \geq 1$, the fall-offs for $\phi$ and $\psi$ readily imply that the symplectic form is divergent for variations coming from the leading solution. In contrast, both solutions are normalizable for for $\nu = 0, 1/2$. The number of normalized modes in terms of $n_p$ for the $p$-form and $p+1$-form sectors are shown in the table 1.

One can also consider the symplectic flux in terms of $\psi$ and $\phi$,

$$\Omega_{\text{flux}}^{(p)} = k_p^2 \int d\tau r^2 \delta \phi^{(m)} \partial_r \delta \phi^{(m)} + k_p^2 \int d\tau \partial_t \left( \delta f^{(m)} \delta \phi^{(m)} \right)$$

$$\Omega_{\text{flux}}^{(p+1)} = \int d\tau r^2 \delta \psi^{(n)} \partial_r \delta \psi^{(n)}$$

Once again we see that for $\nu = 0, 1/2$ the both sectors have vanishing flux independently. For $\nu \geq 1$ however the leading solution has symplectic flux and we have just one mode with vanishing flux. This gauge invariant formulation makes it clear that symplectic flux or symplectic convergence lead to same results for the number of normalizable mode.

| $n_p$ | $p$ sector | $p+1$ sector |
|-------|------------|-------------|
| $< 0$ | 1          | 1           |
| 0     | 1          | 2           |
| 1     | 1          | 2           |
| 2     | 2          | 2           |
| 3     | 2          | 1           |
| 4     | 2          | 1           |
| $> 4$ | 1          | 1           |

**Table 1.** The number of independent normalizable modes for $p$ and $p+1$ form sector. $n_p = d - 2p - 1$.

### Falloff conditions in terms of the gauge field

We conclude this section by reviewing the falloff conditions for the gauge field itself. For simplicity we fix the radial gauge $A_{\mu} = 0$. The falloff conditions for the rest of the components $A_{\mu+1}$ are obtained from those for $\phi$ and $\psi$ as

$$A_{\mu+1}^{[\alpha]} = A_{\mu+1}^{[\alpha]} r^0 + \cdots + A_{\mu+1}^{[\beta]} r^{1-n_p} + \cdots \quad n_p \neq 1$$

$$A_{\mu+1}^{[\beta]} = A_{\mu+1}^{[\beta]} r^0 + \cdots + A_{\mu+1}^{[\beta]} \ln r + \cdots \quad n_p = 1$$

where $A_{\mu+1}^{[\alpha]}$ and $A_{\mu+1}^{[\beta]}$ are the two independent solutions and note that the $[\alpha]$ sector is the leading one when $n_p = 2$ and $[\beta]$ solution is leading for other cases.

### 3 The renormalized action and symplectic form

Before we delve into renormalization, we shortly review the Harlow-Wu method for defining the symplectic form in the presence of corner terms [37]. Then we introduce the counter-terms that make the on-shell action finite. In appendix A, we work out the divergences in the action and the symplectic form explicitly in a few examples.
3.1 Symplectic form in presence of corner terms

Considering a boundary action \( S_b = \int_{\mathcal{I}} L_b \), the boundary term from variation of the total action becomes

\[
\delta(S + S_b) \approx \int_{\mathcal{I}} (\theta^r + \delta L_b). \tag{3.1}
\]

Assume that for a particular boundary condition,

\[
(\theta^r + \delta L_b)|_{\mathcal{I}} = \partial_\mu C^\mu \tag{3.2}
\]

where \( C^\mu \) is a phase space one-form leading to a two-form \( \omega^\mu_C = \delta C^\mu \). According to the Harlow-Wu prescription, the symplectic form of the theory is

\[
\Omega = \int_\Sigma \omega^t + \oint_{\partial \Sigma} \omega^t_C. \tag{3.3}
\]

This expression is manifestly conserved, as the symplectic flux is a total divergence by the boundary condition (3.2), and it is subtracted as two corner terms by the Stokes theorem. Note also that with the boundary condition (3.2), the action principle is satisfied by fixing \( C^\mu \) at initial and final surfaces. In addition, this definition is free from \( Y \) ambiguity.

Having said that, there are situations that we have the following boundary condition

\[
(\theta^r + \delta L_b)|_{\mathcal{I}} = \partial_\mu C^\mu + \mathcal{F} \tag{3.4}
\]

where \( \mathcal{F} \) is a given flux expression, prescribed on physical grounds or some other criterion. The symplectic form (3.3) is not conserved any more and the symplectic flux at the boundary is given by \( \delta \mathcal{F} \). Furthermore, with the flux present, the action principle can not be satisfied,

\[
\delta(S + S_b) \approx \int_{\mathcal{I}} \mathcal{F}. \tag{3.5}
\]

On the boundary of \( \text{AdS} \) spacetime, one can make the flux term \( \mathcal{F} \) vanishes by imposing boundary conditions. However, as we show in the next section, in presence of large gauge transformations, the flux is generically non-vanishing unless further dynamical constraints are imposed.

3.2 Renormalization

In this section, we consider renormalization of the action of a \( p \)-form theory. This is done by introducing an appropriate counter-term which renders both the on-shell action and the variation of the action finite. The key point which is pointed out by Compére and Marolf in [19] is that variation of the counterterm produces divergent corner terms which also renormalize the symplectic form of the theory. This follows from the Harlow-Wu construction of the symplectic form (3.3) for some divergent \( C^\mu \) determined from the counter-terms, and leads to a finite symplectic form.

The appropriate counter-term action would be,

\[
S_{ct}[R] = \int_{r=R}^{\mathcal{I}} L_{ct} = \begin{cases} 
\frac{1}{2(p+1)!} \int_{r=R}^{\mathcal{I}} \sqrt{g} A^{[a]}_{\mu^p+1} F^{[a]}_{\mu^p+1} & n_p \geq 2 \\
\frac{1}{2(p+1)!} \int_{r=R}^{\mathcal{I}} \sqrt{g} A^{[\beta]}_{\mu^p+1} F^{[\beta]}_{\mu^p+1} & n_p < 2 
\end{cases} \tag{3.6}
\]
This in turn leads to $S_{\text{ren}} = \lim_{R \to \infty} (S_{\text{reg}}[R] + S_{\text{ct}}[R])$ and $S_{\text{reg}}[R]$ is the bulk action regularized at the cutoff $R$. $S_{\text{ren}}$ is then the renormalized action. To fix the renormalization scheme, we assume that the counter term (3.6) has no finite term.

The variation of the renormalized action leads to,

$$\delta S_{\text{ren}} = \int \theta^\mu_{\text{ct}} + \Theta \tag{3.7}$$

where $\Theta$ is finite at $R \to \infty$, containing both $A^{[\alpha]}$ and $A^{[\beta]}$ and their variations and it is originated from the bulk action $S$. We dismiss the finite term for the moment and come back to it in the next section. The corner term $\theta^\mu_{\text{ct}}$ on the other hand is divergent and is defined by the relation,

$$\delta L_{\text{ct}} = \delta L_{\text{ct}} \delta A^\nu_{p+1} + \partial^\mu \theta^\mu_{\text{ct}}. \tag{3.8}$$

In practice the “equation of motion” part of $L_{\text{ct}}$ cancel the divergent terms in $\theta^\nu$. The other divergent term $\partial^\mu \theta^\mu_{\text{ct}}$ does not concern the action principle because it is a corner term and is fixed by the initial and final data. However, it leads to a renormalized finite symplectic structure,

$$\Omega_{\text{ren}} = \int_{\Sigma_t} \omega^t_{\text{ren}} = \int_{\Sigma_t} \omega^t + \oint_{\partial \Sigma_t} \omega^t_{\text{ct}} \tag{3.9}$$

Explicit calculations for some of the cases are gathered in the appendix A.

4 Finite boundary term and different choices of flux

After renormalization of the symplectic form with the corner term $\theta_{\text{ct}}$, we turn our attention to the finite term $\Theta$ in (3.7) which turns out to be,

$$\Theta = \frac{c_p \sqrt{h}}{(p+1)!} A^{[\beta]}_{p+1} \delta A^{[\alpha]}_{p+1}, \quad c_p \equiv n_p - 1 - \delta n_{p,1}. \tag{4.1}$$

Note that after fixing the radial gauge we have the residual gauge transformations, $\delta \lambda_{\mu \nu} = (p+1) \partial_\mu \lambda_{\nu}^\rho$ where $\lambda_{\mu \nu}^\rho$ is independent of $r$. Hence, $A^{[\beta]}$ is gauge invariant while $A^{[\alpha]} = \hat{\Theta}(1)$ is not invariant under the residual gauge transformations.

Using the following decomposition

$$A^{[\alpha]}_{\mu \nu} = \hat{A}^{[\alpha]}_{\mu \nu} + (d \varphi)_{\mu \nu} \tag{4.2a}$$

$$A^{[\beta]}_{\mu \nu} = \hat{A}^{[\beta]}_{\mu \nu} + (d \Phi)_{\mu \nu} \tag{4.2b}$$

where $\hat{A}^{[\alpha]}_{\mu \nu}$ is gauge invariant and $(d \varphi)_{\mu \nu} = (p+1) \partial_\mu \varphi_{\nu}$. We continue to decompose the $\Theta$ term into a gauge invariant term and a term containing $\varphi_{\nu}$ which represents the gauge variable of the system. Note that $\Phi_{\nu}$ is gauge invariant (see the appendix B for details). The decomposition (4.2a) leads to a decomposition in $\Theta$ as We have

$$\Theta = \hat{\Theta} + \Theta_{\varphi} \tag{4.3}$$
where

\[ \Theta = \frac{c_p \sqrt{h}}{(p+1)!} A_{[\beta]}^{\mu \nu \rho} \delta \hat{A}_{\nu}^{[\alpha\rho]} \]  
(4.4)

\[ \Theta_\varphi = \frac{c_p \sqrt{h}}{p!} A_{[\beta]}^{\mu \nu \rho} \delta \varphi_{\nu}^{[\alpha \rho]} \]  
(4.5)

Now fixing the gauge variable \( \varphi \) on the boundary, or assuming that the gauge transformations vanish near the boundary, leads to vanishing of \( \Theta_\varphi \) term. Therefore, we are left with a gauge-invariant boundary term \( \hat{\Theta} \) to be dealt with by imposing boundary conditions. In particular, by adding finite boundary actions one can eliminate the contribution form \( \hat{\Theta} \) and make the action principle well-defined (reviewed in the appendix C). In presence of non-vanishing gauge parameter on the boundary, we are still left with \( \Theta_\varphi \). Using the language of (3.4), suppose that there is a prescribed flux term \( \mathcal{F} \) such that

\[ \Theta_\varphi = \partial_\mu C^\mu + \mathcal{F} \]  
(4.6)

for some \( C^\mu \). In what follows, we examine specific expressions for flux terms \( \mathcal{F} \) and corresponding surface charges.

**4.1 The Conservative approach** \( \mathcal{F} = 0 \)

Among the choices we have, there is a special case where we take the system to be completely conservative. This can be done by taking the decomposition (4.6) such as,

\[ C^\mu = \frac{c_p \sqrt{h}}{p!} A_{[\beta]}^{\mu \nu \rho} \delta \varphi_{\nu}^{[\alpha \rho]} \]  
(4.7)

\[ \mathcal{F} = 0 \]  
(4.8)

where we have used the leading term of constraint equation (2.4), \( D_\mu A_{[\beta]}^{\mu \nu \rho} \approx 0 \). Then, the symplectic form will be deformed as,

\[ \Omega_\circ = \int_{\Sigma_t} \omega^\text{ren} + \omega^t + \oint_{\partial \Sigma_t} \delta C^\circ. \]  
(4.9)

This choice is interesting as guarantees conservation by setting the flux to zero. As it turns out, the surface charges are vanishing

\[ \Omega_\circ (\cdot, \delta \lambda) = \delta Q_\lambda = 0. \]  
(4.10)

The reason is that, the corner-term exactly cancels a similar term coming from the bulk symplectic form \( \omega^\text{ren} \). To show this, using the decomposition (4.2a), dependence of the bulk symplectic form on \( \varphi \) can be isolated:

\[ \int \omega^\text{ren} = \frac{1}{(p+1)!} \int \sqrt{g} \delta A_{\nu}^{[\rho]} \delta \mathcal{F}^\rho_{\nu} \approx \int \omega^t_{\text{ren,gi}} \]  
(4.11)
where $\omega^t_{\text{ren,gi}}$ is the renormalized symplectic form free of the gauge variable $\varphi$. In consequence, the total symplectic form is gauge invariant (i.e. annihilated by all gauge transformations)

$$\Omega = \int_{\Sigma_t} \omega^t_{\text{ren,gi}}. \quad (4.12)$$

The action principle is satisfied with this choice.

### 4.2 Leaky boundary condition $\Delta$

Another possibility in defining the charges is to allow non-zero flux as

$$C^\mu_{\Delta} = 0 \quad (4.13a)$$

$$F_\Delta = \frac{c_p \sqrt{h}}{p!} A_{[\beta]}^{\mu} D_{[\mu} \delta \varphi_{\nu]} \quad (4.13b)$$

together with the boundary gauge condition,

$$\dot{\varphi}_{p^\nu} = 0 \quad (4.14)$$

where the notation $\Delta$ will be clarified in a moment. With this choice where $C$ is taken to be zero, the original (renormalized) symplectic form is not deformed,

$$\Omega_\Delta = \int_{\Sigma_t} \omega^t_{\text{ren}} \quad (4.15)$$

and from $(4.11)$ it can easily be seen that the charges are,

$$Q_\lambda = \frac{1}{p!} \oint \lambda_i F_{[\beta]} \quad (4.16)$$

where $F_{[\beta]}$ is the radial component of the electric field at order $O(r^{-n_p})$. Note that we brought up the indices of $F_{[\beta]}$ using the boundary metric $h_{\mu\nu}$ where $F_{[\beta]} = -c_p A_{[\beta]}$. Also, recall from section 2 that the radial electric field is determined exclusively by the $p$-form components $\phi$. We may cast the expression $(4.16)$ into another form recalling from $(2.23)$ that $F_{[\beta]} \approx \sum k_p^{2} \phi^{(k,0)} T_{[\beta]}^{(k)}$ where $\phi^{(k,0)}$ is the leading $O(1)$ order term of $\phi$. Taking the gauge parameter as one of the spherical harmonic $p$-forms $T_{[\beta]}^{(k)}$ gives us the charge,

$$Q_{(k)} = k_p^{2} \phi^{(k,0)}. \quad (4.17)$$

**Flux** The boundary gauge fixing $(4.14)$ makes the large gauge transformations time-independent. Using the constraint equation $(2.4)$ we have $\partial_t A_{[\beta]} = \Delta \Phi$. In consequence, we can rewrite the flux term as

$$F_\Delta = -\frac{c_p \sqrt{h}}{p!} \Delta \Phi \delta \varphi_{p^\nu}. \quad (4.18)$$

Therefore, the flux term in proportional to the term $\Delta \Phi$ which justifies the notation $\Delta$. In terms of $\phi$ this is simply $F_{(k)} = k_p^{2} \phi^{(k,0)}$. Restricting ourselves to the case where $\dot{\phi}^{(k,0)} = 0$ leads to vanishing flux and then conservation of the multipole charges. This restriction however does not concern the dynamic of the $\psi$ i.e. the $(p + 1)$-form sector where their dynamics are decoupled. The interesting situation might be however the electrostatic case, where $\partial_t F_{[\beta]} = 0$ implies that $\Phi = 0$ and so vanishing the flux. But this is however, a much smaller phase space on which the above charge are conserved.
**Exact parameters.** The genuine feature of higher form theories with respect to Maxwell theory is the possibility of gauge parameters which are exact; \( \lambda^p = (de)^p \). Nevertheless, if \( F_{[\beta]}^p \) is a regular \( p \)-form on sphere, exact parameters will have vanishing charge by equations of motion.

**Harmonic parameters.** The flux term can be written equivalently as,

\[
\mathcal{F}_\Delta = \frac{-c_p \sqrt{h}}{p!} \Phi^p \delta \Delta \varphi^p
\]

so it is vanishing for harmonic parameters on the sphere. The gauge parameter \( \lambda^p \) can be closed but not exact. We assume the the boundary of \( AdS \) has the topology \( \mathbb{R} \times K \) where \( K \) is a compact manifold. If \( K \) is a \( n = d - 1 \) dimensional sphere (as it has been assumed so far), the harmonic forms are either the constant function \( (p = 0) \) or the volume form \( (p = n) \).

The former case is the Maxwell theory in any dimension and the harmonic parameter gives the electric charge in the bulk (the Gauss’ law). The second possibility, the field strength \( \mathcal{F} \) is a top-form in spacetime. The theory has no propagating degrees of freedom, and the only solution to it is \( \mathcal{F} = c \text{Vol}_{d+1} \). The only non-vanishing charge belongs to the harmonic parameter and is proportional to \( c \), the value of the constant electric field in space.

There are more interesting possibilities for the harmonic parameter if \( K \) has non-trivial topology. If there are \( p \)-form gauge parameters that are closed but not exact around some non-trivial cycle, the value of the charge gives the electric flux through that cycle.

**4.3 Leaky boundary condition**

There is another choice of the flux term which leads to an interesting set of charges. Consider the following boundary condition,

\[
\mathcal{C}^\mu = \frac{c_p \sqrt{h}}{p!} \left( A^\mu_{[\beta]} \delta \varphi^p + \Phi^p (d \delta \varphi)^{\mu\nu} \right)
\]

\[
\mathcal{F}^\mu = \frac{-c_p \sqrt{h}}{p!} \partial_{\nu} A^\mu_{[\beta]} \delta \varphi^p
\]

where we have used the boundary gauge fixing,

\[
\Box \varphi^p \equiv D^\mu D_{[\mu} \varphi_{p]} = 0,
\]

Now the symplectic form is deformed by the boundary term \( \mathcal{C} \) where it deviates from conservation by the above flux term. The symplectic form is given by,

\[
\Omega = \int_{\Sigma_t} \omega^t_{\text{ren}} + \oint_{\partial \Sigma_t} \delta \mathcal{C}^t.
\]

Using (4.11) and bringing the gauge mode \( \varphi \) on the boundary, and working in a temporal gauge-for-gauge condition, \( \varphi_{t=0} = 0 \) we arrive at 4.

\[
\Omega = \int_{\Sigma_t} \omega^t_{\text{ren},g} + \frac{c_p}{(p!)} \oint_{\partial \Sigma_t} \sqrt{q} \left( \delta \varphi^p \delta \Phi^p + \delta \Phi^p \delta \varphi^p \right)
\]

\[
\Omega = \int \frac{dr}{(r^2 + 1)} \left( k^2 \delta \Phi^p \delta \Phi^p + \delta \Phi^p \delta \Phi^p \right) + \left( \delta \Phi^p \delta f_{(k)} - \delta \Phi^p \delta f_{(k)} \right) |_{\mathcal{F}}.
\]

4 We can write this symplectic form in terms of the gauge invariant functions \( \phi \) and \( \psi \) which would amount to,

\[
\Omega = \int \frac{dr}{(r^2 + 1)} \left( k^2 \delta \hat{\phi} \delta \hat{\phi} + \delta \hat{\phi} \delta \hat{\phi} \right) + \left( \delta \hat{\phi} \delta \hat{f}_{(k)} - \delta \hat{\phi} \delta \hat{f}_{(k)} \right) |_{\mathcal{F}}.
\]
The charges then will be,
\[ Q_\lambda = \frac{-c_p}{(p!)} \oint_{\partial \Sigma_t} \sqrt{q} \left( \lambda^{\mu \nu} \Phi_{p}^{\mu} - \Phi_{p}^{\nu} \dot{\lambda}_{p}^{\nu} \right). \tag{4.26} \]

In this case we can rewrite the charge in terms of the \( \phi \). To do this, note that we had,
\[ F_{p}^{[\beta]} = \sum \left( \dot{\phi}^{(k,0)} dT_{p}^{(k)} \right) \tag{4.27} \]
for the \( p \)-form component (exact component) of the tangent “magnetic fiel”. In terms of the gauge field, this is just \(-c_p(d\Phi)^{p+1}_p\). So we have,
\[ \Phi_{p} = \frac{-1}{c_p} \sum \left( \dot{\phi}^{(k,0)} T_{p}^{(k)} \right) \tag{4.28} \]
up to an exact form on the sphere. On the other hand we had the boundary gauge fixing (4.22). Take \( \lambda_p = \lambda(t) T_{p}^{(k)} \) subject to
\[ \ddot{\lambda} + k_p^2 \lambda = 0. \tag{4.29} \]
The charges (4.26) may be rewritten as,
\[ Q^\beta_\lambda = \lambda \ddot{\phi}^{(k,0)} - \dot{\lambda} \dot{\phi}^{(k,0)}. \tag{4.30} \]
Note that for any \( k \) we have two independent solution of the equation (4.29) and so two independent charges for any \( k \). So the cardinality of this set of charges is twice the previous set (4.17).

**Flux** Again, using the constraint equations (2.4) this time written as \( \partial_t \hat{A}_{\beta}^{p} + \Box \Phi_{p}^{\beta} = 0 \), we can rewrite the flux as,
\[ \mathbf{F} = \frac{c_p \sqrt{h}}{p!} \Box \Phi_{p}^{\beta} \delta \varphi_{p}^{\beta}. \tag{4.31} \]
In term of \( \phi \) and using the boundary gauge fixing for \( \lambda \), it becomes
\[ \mathbf{F}_\lambda = \lambda \partial_t \left( \ddot{\phi}^{(k,0)} + k_p^2 \phi^{(k,0)} \right). \tag{4.32} \]
From the equations of motion (2.24) we have,
\[ \ddot{\phi}^{(k,0)} + k_p^2 \phi^{(k,0)} = 2c_p \phi^{(k,2)} \tag{4.33} \]
where \( \phi^{(k,2)} \) is the sub-leading component at \( r^{-2} \). So we see that the flux of these set of charges is simply,
\[ \mathbf{F}_\lambda = 2c_p \lambda \dot{\phi}^{(k,2)} \tag{4.34} \]
In contrast with the previous set of charges, the requirement of conservation of this charges do not kill the dynamic of \( \phi \) completely. We still have the “boundary dynamic” of \( \phi^{(k,0)} \) as is (4.33).

Cause \( \phi \) is the radial electric field, the condition \( \dot{\phi}^{(k,2)} = 0 \) amounts to a constant radial electric field, *but not at leading order*. Thus, a weaker condition is needed for the charge (4.26) to be conserved with respect to the standard expression (4.16).
**Exact charges** Note that $\varphi_p$ and $\Phi_p$ is defined up to exact forms on the sphere. So they are in fact in an equivalence class by the relations

\[ \Phi_p \sim \Phi_p + (d\zeta)_p \]  
\[ \varphi_p \sim \varphi_p + (d\chi)_p \]  

(4.35)  
(4.36)

This ambiguity in $\Phi$ does not change the co-exact charge defined above, because $\lambda$ is defined to be a co-exact form and so the co-exact charge is only sensitive to the class itself. However there is two set of charges that measure the specific element in the class. Note that after using the exact gauge transformations to set the gauge fixing $\Phi_{p-1} = 0$ and $\varphi_{p-1} = 0$ we remain with the residual exact gauge transformations,

\[ \delta \epsilon \Phi_p = (de)_p \]  
\[ \delta \epsilon \varphi_p = (d\epsilon)_p \]  

Taking the exact gauge transformations as, $\epsilon_p = \epsilon(t)\Gamma^{(k)}_p$ and $\tilde{\epsilon}_p = \tilde{\epsilon}(t)\Gamma^{(k)}_p$, the charges will be the followings,

\[ Q^{(k)}_\epsilon = c_p k_{p-1}^2 \left( \chi^{(k)} - \epsilon \chi^{(k)} \right) \]  
\[ Q^{(k)}_{\tilde{\epsilon}} = c_p k_{p-1}^2 \left( \zeta^{(k)} - \tilde{\epsilon} \zeta^{(k)} \right) \]  

(4.39)  
(4.40)

where amounts to the Heisenberg charge algebra,

\[ \{Q^{(k)}_\epsilon, Q^{(k')}_{\tilde{\epsilon}}\} = c_p k_{p-1}^2 \left( \epsilon \tilde{\epsilon} - \tilde{\epsilon} \tilde{\epsilon} \right) \delta_{kk'} \]  

(4.41)

Note however that these exact charges are not physical because there is no way to measure $\zeta$ and $\chi$. They are just the reflection of the fact that $\Phi$ and $\varphi$ are well-defined up to exact $p$-forms on the sphere. Assuming that the functions $\epsilon(t)$ and $\tilde{\epsilon}(t)$ satisfy the following equation on the boundary,

\[ \ddot{\epsilon} + k^2_{p-1} \epsilon = 0, \]  
\[ \ddot{\tilde{\epsilon}} + k^2_{p-1} \tilde{\epsilon} = 0 \]  

(4.42)  
(4.43)

leads to conservation of these charges.

### 4.4 A subset of the phase space with conserved charges

As we saw in the previous section, putting the boundary condition $\phi^{(k,2)} = 0$ leads to a set of conserved charges in terms of the exact $p$-form components of the tangent magnetic field on the boundary. Now, lets put $\phi^{(k,2)}$ and all the sub-leading components of $\phi$ equal to zero. So we only have $\phi = \phi^{(k,0)}$ which obviously is a asymptotic solution to the equations of motion (2.24), if it satisfies,

\[ \ddot{\phi}^{(k,0)} + k_{p}^{2} \phi^{(k,0)} = 0. \]  

(4.44)

These solutions near the boundary can be achieved in terms of the gauge field as well. Consider again the equations of motion (2.5) in terms of the gauge field in the radial gauge

\[ \left[ \frac{r^{p}}{r} + \partial_{r} \right] \partial_{r} A_{\mu r p+1} + r^{-4} D^\mu F_{\mu r p+1} = 0 \]  

(4.45)
where $\bar{D}^{\mu} = h^{\mu\nu} D_{\nu}$. Consider the following exact solution for the $p + 1$-form gauge field for $n_p \neq 1$

$$A_{\mu\nu} = r^{1-n_p}(d\Phi)_{\nu}$$

(4.46)

where $\Phi_{\nu} = \Phi_{\nu}(x^\mu)$ and we consider $\Phi_{n_p-1} = 0$. So, we have $F_{\mu\nu}^{p+1} = 0$ and this leads to vanishing of the second term of (4.45). The rest of the equations of motion is satisfied with the $r$ profile of the above solution. Note that if we expand this solution in terms of $r$ it only contains the $r_1 - n_p$ order where the co-exact part is switched off, $\hat{A}_{\mu\nu} = 0$, and the exact part is just the same $\Phi_{\nu}$ here. Note that although $F_{\mu\nu}^{p+1}$ is vanishing, the radial electric field and the tangential magnetic field are non-vanishing,

$$F_{r\mu\nu} = -c_p r^{-1} A_{\mu\nu}.$$ 

(4.47)

There are no subleading terms in this solution, and the dynamics is governed by the constraint equation

$$\ddot{\Phi}_{\nu} - D^k (d\Phi)_{\nu}^{k} = 0.$$ 

(4.48)

The surface charge (4.26) is conserved for this configuration and the integrand is a local function of $\Phi_{\nu}$. So they are separately solutions to the first term and the second term of (A.11), where the second term is a Maxwell type equations of motion on the boundary.

Note that we only considered the asymptotic form of the solution here. However, we can interpolate this solution to the bulk and glue that to another form of solution with appropriate sources.

5 Electric/Magnetic duality and magnetic charges

The $(p + 1)$-form theory with gauge field $A_{L^{p+1}}$ can be written in terms of the dual gauge field $\tilde{A}_{\tilde{L}^{p+1}}$, such that

$$\tilde{F}_{\tilde{L}^{p+2}} = \frac{1}{(p+2)!} \tilde{F}_{\tilde{L}^{p+2}} F_{\tilde{L}^{p+2}}$$

(5.1)

where $\tilde{p} = n - p - 2$ and with the same form for the action

$$S = \frac{1}{2(p+2)!} \int \sqrt{g} F_{\tilde{L}^{p+2}} F_{\tilde{L}^{p+2}} = \frac{1}{2(\tilde{p}+2)!} \int \sqrt{g} \tilde{F}_{\tilde{L}^{p+2}} \tilde{F}_{\tilde{L}^{p+2}}.$$ 

(5.2)

In section 2 the $p + 1$-form fields were decomposed into spherical harmonics $p$ and $p + 1$ forms and the functions $\phi^{(k)}$ and $\psi^{(k)}$ respectively. The normalization (2.10) implies that under Hodge duality on $n$-sphere

$$\sqrt{k_p^2} \frac{1}{p!} \epsilon_{i_1 \cdots i_p j_1 \cdots j_{n-p}} T^{(k)}_{i_1 \cdots i_p} = (n - p) \partial_{[j_1} T^{(k)}_{j_2 \cdots j_{n-p}]}.$$ 

(5.3)

Using this relation we can read the dual fields as,

$$\tilde{\phi}^{(k)} = \frac{(-1)^{p d}}{\sqrt{k_{p+1}^2}} \psi^{(k)}, \quad \tilde{\psi}^{(k)} = -\sqrt{k_p^2} \phi^{(k)}.$$ 

(5.4)

$^5$For $n_p = 1$, the discussion is similar but the behavior of the gauge field is logarithmic as in (2.33).

$^6$See the appendix D.
where ̂φ(k) and ̂ψ(k) are associated functions of ̂p and (̂p + 1) form components.

Relations (5.4) are true at any order of r expansion. In terms of the field strength and the [α] and [β] modes we have\(^7\),

\[
\begin{align*}
\tilde{A}^{[\beta]}_{L^p+1} &= \frac{(-1)^{d-p}}{c_p(d-p-1)!} \ell^{L^d-p-1} F^{[\alpha]}_{L^d-p-1} \\
\tilde{F}^{[\alpha]}_{L^d-p} &= \frac{c_p}{(p+1)!} \ell^{L^p+1} \psi^{p-1} A^{[\beta]}_{L^p+1}
\end{align*}
\]

where the Hodge dual is on the boundary. In addition, under the electric-magnetic duality Dirichlet conditions map to Neumann conditions.

### 5.1 Magnetic charges

The electric charges are associated with gauge transformations that are non-zero on the boundary. In contrary, it is not possible to obtain magnetic charges from such symmetry principles. However, we can define magnetic charges of a \(p+1\)-form theory in AdS\(_d+1\) as follows,

\[
Q_M^\lambda = \oint \lambda \wedge F^{[\alpha]} = \frac{1}{p!(p+2)!} \oint \sqrt{q} \epsilon^{\rho \mu \nu} \lambda^{\rho} F^{[\alpha]}_{\mu \nu}.
\]

Note that while the gauge parameter of the electric charges (in a \((p+1)\)-form gauge theory) is a \(p\)-form \(\lambda^\rho\), the parameter in the magnetic charges (in the same theory) is a \(\tilde{p} = (n-p-2)\)-form \(\tilde{\lambda}^\rho\). Taking \(\tilde{\lambda}^\rho\) a \(p\)-form spherical harmonic \(\mathbb{T}_{p}^{(k)}\) and using the fact that \(k_p^2 = k_{p+1}^2\) we arrive at,

\[
Q_M^{(k)} = \frac{k_{p+1}^2}{\sqrt{k_p^2}} \psi^{(k,0)}
\]

which can be compared to electric charges (4.17). Note that as mentioned previously, \(\psi\) exists only when \(n > p + 1\), which is equivalent to \(\tilde{p} > -1\). If \(n = p + 1\) (i.e. \(\tilde{p} = -1\)), the dual theory is a scalar field, thus is has no electric charges. The simplest example is \(p = 0, n = 1\), the Maxwell theory in three dimensions.

**Magnetic charge as the electric charge of the dual theory**  Note that if we reformulate \((p+1)\)-form theory as a \((\tilde{p} + 1)\)-form theory as we did above and seek for the standard electric charge of this dual theory we arrive at,

\[
\tilde{Q}^{(k)} = \frac{1}{p!} \oint \lambda^{\rho} \tilde{F}^{\rho \mu \nu} = k_p^2 \tilde{\phi}^{(k,0)}
\]

which is exactly the magnetic charge (5.7) up to a sign, according to (5.4). So with this observation we advocate the following definition of the magnetic charges for a \((p+1)\)-form theory,

\[
Q^M \equiv \tilde{Q}
\]

where \(\tilde{Q}\) are the electric charges of the dual theory which is a \((\tilde{p} + 1)\)-form theory. With this proposal we can define other set of magnetic charges as,

\[
Q_M^{(k)} = \frac{1}{\sqrt{k_{p+1}^2}} \left( \hat{\lambda}^{(k,0)} - \hat{\psi}^{(k,0)} \right)
\]

\(^7\)\(\tilde{A}^{[\alpha]}_{L^p+1}\) is not gauge-invariant and only its derivatives appear in duality relations.
where \( \lambda \) satisfies,

\[
\ddot{\lambda} + k_p^{2} \lambda = 0. \tag{5.11}
\]

The flux of this set of charges then will be proportional to \( \dot{\psi}^{(k,2)} \). In terms of the gauge field, this charges are coming from the co-exact sector of the tangent electric field at the order \( \mathcal{O}(1) \).

Note that, we can define the magnetic charges as Noether charges of the dual theory, but in the dual description, the notion of electric charges as Noether charges of the original theory is lost. We also can go for the dual description only for the \( \psi \) sector and have both charges as Noether charges, but we cannot maintain the covariance of the theory. For a recent formulation of magnetic charges as the charges of a Noether symmetry, see [38] where they have obtained magnetic charges from first order formulation of \( p \)-form theory in terms of Abelian BF theory.

**Duality invariance in \( n_p = 2 \)**  
If \( d = 2p + 3 \), the Hodge dual field strength tensors have the same rank as \( p = \hat{p} \). This happens for Maxwell theory in four dimensions \( (p = 0, d = 3) \), 2-form theory in six dimensions \( (p = 1, d = 5) \) etc. Note also that, under the duality the gauge invariant part of the symplectic form (2.31) (i.e. the bulk term) maps to itself. In fact, in these cases the system has a \( SO(2) \) symmetry which is a rotation in \( \psi \) and \( \phi \) variables. This symmetry is however broken in the presence of the boundary and the gauge mode \( \varphi \) (\( f \) in (2.7)) on it, as the term \( (k_p^{2} \delta \dot{\phi}^{(k)} | \delta \phi^{(k)} \rangle \mathcal{J} \) in (2.32a) or the term \( \langle \delta \ddot{\psi}^{(k)} | \delta \dot{f}^{(k)} - \delta \dot{\phi}^{(k)} | \delta \dot{f}^{(k)} \rangle \mathcal{J} \) in (4.24) are not invariant under this duality. We can however construct symplectic forms that are completely \( SO(2) \) invariant by introducing the magnetic gauge variable \( g \) which is naturally conjugate to the \( \psi \) on the boundary. For example, in the standard form (2.32a) we can add the term, \( (\delta \psi^{(k)} | \delta \varphi^{(k)} \rangle \mathcal{J} \) which leads to a duality invariant symplectic form for a theory with \( n_p = 2 \).

\[
\Omega_{\text{di}} = \int \frac{dr}{(r^2 + 1)} \left( k_p^2 \delta \dot{\phi}^{(k)} | \delta \phi^{(k)} \rangle + \delta \dot{\psi}^{(k)} | \delta \psi^{(k)} \rangle \right) + \left( k_p^2 \delta \dot{\phi}^{(k)} | \delta f^{(k)} + \delta \dot{\psi}^{(k)} | \delta g^{(k)} \rangle \right) \mathcal{J}. \tag{5.12}
\]

Then, we see that this symplectic form is invariant under \( \delta_{\theta} \) which is the infinitesimal generator of the \( SO(2) \) symmetry and is defined as,

\[
\delta_{\theta} \sqrt{k_p} \phi^{(k)} = \psi^{(k)} \quad \delta_{\theta} \phi^{(k)} = -\sqrt{k_p} \psi^{(k)}, \tag{5.13a}
\]

\[
\delta_{\theta} \sqrt{k_p} f^{(k)} = g^{(k)} \quad \delta_{\theta} g^{(k)} = -\sqrt{k_p} f^{(k)}. \tag{5.13b}
\]

where the charge will be,

\[
Q_{\theta} = \sqrt{k_p} \int \frac{dr}{(r^2 + 1)} \left( \dot{\phi}^{(k)} \psi^{(k)} - \dot{\psi}^{(k)} \phi^{(k)} \right) + \sqrt{k_p} \left( \ddot{\phi}^{(k)} g^{(k)} - \ddot{\psi}^{(k)} f^{(k)} \right) \mathcal{J} \tag{5.14}
\]

with the algebra,

\[
\{ Q_{\theta}, Q \} = Q^M, \quad \{ Q_{\theta}, Q^M \} = -Q. \tag{5.15}
\]

**6 Integrability**

The electric surface charges in \( p + 1 \)-form theory are integrable as long as the gauge parameter is not field-dependent. This is not the case for the charges of AdS isometries. For instance,
including boundary modes modifies the energy of the system by surface terms. As it turns out, the general form of the energy computed as $\Omega(\cdot, \delta t)$ will not be integrable in the presence of the gauge mode $f$ (or $\varphi$) by a non-integrable boundary term. The integrable bulk term is universal and is given by the standard energy-momentum tensor as expected,

$$E_{\text{bulk}} = \frac{1}{2} \int \frac{dr}{(r^2 + 1)} \left[ k_p^2 \left( \dot{\phi}^2 + \phi A_0 \dot{\phi} + (\psi^2 + \psi A_1 \psi) \right) \right]$$

(6.1)

where $A_0$ and $A_1$ are differential operators in the equations of motion (2.25) and (2.15) as $\ddot{\phi} = -A_0 \phi$ and $\ddot{\psi} = -A_1 \psi$. Sum over the different spherical modes $(k)$ is assumed here. The extra non-integrable part denoted as $\delta E$ is different using different symplectic forms. We have,

$$\delta E_\circ = 0$$

(6.2a)

$$\delta E_\Delta = -\sum k_p^2 \dot{\phi}_{(k,0)}^2 \delta f_{(k)} = -\mathcal{F}_\Delta$$

(6.2b)

$$\delta E_\Box = -2c_p \sum k_p^2 \dot{\phi}_{(k,2)} \delta f_{(k)} = -\mathcal{F}_\Box.$$  

(6.2c)

Clearly, the energy is integrable when the associated fluxes are vanishing and the surface charges are conserved. In the third case, there is also an extra integrable contribution from the boundary modes to the energy,

$$E_\Box = \sum \dot{\phi}_{(k,0)}^2 f_{(k)} + k_p^2 \dot{\phi}_{(k,0)}^2 f_{(k)}.$$  

(6.3)

7 Concluding Remarks

In this paper we computed the surface charges for a $(p+1)$-form theory on $\text{AdS}_{d+1}$ associated with the gauge mode on the boundary of spacetime assuming the usual reflective boundary condition modulo residual gauge transformations. This results in infinite dimensional Abelian symmetry algebra. Different expressions for the charge are possible depending on the flux expression, leading to different boundary terms of the symplectic form. We studied three cases of interest where the results summarized in table 2. The first one was a conservative boundary condition which resulted in an empty set of charges. Similarly to the recent gravity studies [21], here we see that demanding infinite dimensional asymptotic charges in incompatible with conservative boundary conditions. So, in two of these cases, we choose a leaky boundary condition where there is a non-trivial flux through the boundary unless further assumptions on the dynamics is made.

By proposing a generic counter-term, we showed how the divergences in the on-shell action are subtracted in various cases. In addition, we explicitly showed how variation of the counter term on the boundary leads to divergent corner terms which render the symplectic form finite. This procedure has also been applied in Maxwell theory in flat space [34]. The charges are then finite by construction as they are built out of the renormalized symplectic form.

Boundary conditions advocated here are similar to the usual reflective boundary conditions, as the gauge field on the boundary is fixed up to gauge transformations. Energy as defined by the bulk integration of the energy-momentum tensor is finite and conserved. However, covariant phase space formalism predicts a boundary term for the energy depending on the pure gauge mode. This new piece spoils integrability and conservation of the energy despite the lack of radiation through the boundary.
\[ F = 0 \quad \Delta = \Delta \Phi_i^p \delta \varphi_i^p \quad \Box = \Box \Phi_i^p \delta \varphi_i^p \]

\[ \Omega \int \omega_{\text{ren},gl}^i \int \omega_{\text{ren}}^i + \frac{c_p}{12 \pi} \oint \sqrt{q} \left( \delta \varphi_i^p \delta \Phi_i^p + \delta \Phi_i^p \delta \varphi_i^p \right) \]

\[ Q(k) \int k^2 \delta(k,0) \left( \lambda \dot{\varphi}_i^p - \dot{\lambda} \dot{\varphi}_i^p \right) \]

\begin{table}[h]
\begin{tabular}{|c|c|c|}
\hline
$F$ & $\Delta$ & $\Box$ \\
\hline
$0$ & $\Delta \Phi_i^p \delta \varphi_i^p$ & $\Box \Phi_i^p \delta \varphi_i^p$ \\
\hline
$\Omega$ & $\int \omega_{\text{ren},gl}^i \int \omega_{\text{ren}}^i$ & $\int \omega_{\text{ren},gl}^i + \frac{c_p}{12 \pi} \oint \sqrt{q} \left( \delta \varphi_i^p \delta \Phi_i^p + \delta \Phi_i^p \delta \varphi_i^p \right)$ \\
\hline
\end{tabular}
\end{table}

Table 2. This table summarizes our main results. $F$ is the flux. $\Phi_i^p$ is the exact part of the tangent “magnetic field” $\mathcal{F}_i^{p+1}$. $\varphi_i^p$ is the gauge mode and $\phi(k,0)$ is the gauge invariant $p$ component defined in (2.19). $\Delta$ and $\Box$ are also the Laplacian operators respectively on the sphere and on the cylinder. $Q(k)$ is the surface charge smeared on $p$-form spherical harmonics.

Finally, we only considered Maxwell-like actions, whereas Chern-Simons theories can be studied along the same lines. These theories besides being physically interesting, have a rich asymptotic structure and boundary dynamics.

Acknowledgements

A Holographic renormalization of action and the symplectic form

We show that adding the counter term (3.6) makes the on-shell action, variation of the action, and the symplectic form finite.

On-shell action and variation of the action

\[ S_{\text{reg}}[R] \approx -\frac{1}{2(p+1)!} \int_{r=R} d^p x \sqrt{g} A^{\mu+1}_i \mathcal{F}^{\nu+1}_i \]  

(A.1)

According to fall-offs (2.33), the divergent terms come from $A_{[\alpha]}$ modes in $n_p \geq 2$ and from $A_{[\beta]}$ modes in $n_p < 2$. Thus, the counterterm (3.6) cancels the divergences trivially. This leads to,

\[ S_{\text{on-shell}}^{\text{on-shell}} = \frac{c_p}{2(p+1)!} \int_{\mathcal{F}} d^p x \sqrt{h} A^{[\beta]}_{\nu+1} A^{\mu+1}_{[\alpha]} \]  

(A.2)

On the other hand, the variation of the renormalized action is turned out to be,

\[ \delta S_{\text{ren}} = \frac{c_p}{(p+1)!} \int_{\mathcal{F}} d^p x \sqrt{h} A^{[\beta]}_{\nu+1} \delta A^{\mu+1}_{[\alpha]} \]  

(A.3)

Symplectic form

In the radial gauge, the symplectic form is,

\[ \Omega = \frac{1}{(p+1)!} \int \sqrt{q} d^p x \delta A^{\mu+1}_i \delta \mathcal{F}^{\nu+1}_i = \frac{1}{(p+1)!} \int \sqrt{q} d^p x \delta A^{\mu+1}_i \delta \mathcal{F}^{\nu+1}_i \]  

(A.4)
where the term $\delta A_{ri} \delta F_{tri}^{p}$ drops out of the symplectic form. This has crucial consequences. First note that in this gauge fixed approach, the $p$-form and $(p+1)$-form components have the same contribution in the bulk symplectic form. One can see the symplectic form as a $p$-form sector plus a $(p+1)$-form sector, $\delta A_{ri}^{(p)} \delta F_{ri}^{(p)} + \delta A_{ri}^{(p+1)} \delta F_{ri}^{(p+1)}$ where the term $\delta A_{ri}^{(p)} \delta F_{tri}^{p}$ is absent due to radial gauge. We will see that for example in $n_p = 0, 1$ this fact leads to the conclusion that we have two normalizable modes for both $p$ and $(p+1)$-form sector, in contrast to the gauge invariant approach where we were working with gauge invariant quantities $\psi$ and $\phi$ in the section 2.2. Specifically in the table 1, we had 2 normalizable modes for $p+1$ components and 1 normalizable mode for $p$-form components sector in that gauge invariant approach.

Now we review how the holographic renormalization of the action eliminates some divergences of the symplectic form and leads to finite one in some cases.

$n_p = 0$ While the action is divergent in this case and need to be renormalized, the symplectic form is finite as we explained above. One can see this by writing the symplectic form expansion,

$$\Omega = \int \sqrt{q} d^n x^i drr^{-4} (1 - r^{-2} + \cdots) \delta (F_{ti}^{[\beta]} r + \cdots) \delta (A_{ri}^{p+1} r + \cdots) \sim \text{finite}$$

(A.5)

where the leading term in the symplectic density is $O(r^{-2})$ and so normalizable. On the other hand, the variation of the action has the following divergent term,

$$\delta S_{div} \approx -\frac{1}{(p+1)!} \int \sqrt{h} \left( r A_{ri}^{[\beta]} \delta A_{ri}^{p+1} \right)$$

(A.6)

which is cured by the renormalization.

$n_p = 1$ This case is also like the previous one. One can see that the symplectic form is convergent thanks to the radial gauge,

$$\Omega = \int \sqrt{q} d^n x^i drr^{-3} (1 - r^{-2} + \cdots) \delta (F_{ti}^{[\beta]} \ln r + \cdots) \delta (A_{ri}^{p+1} \ln r + \cdots) \sim \text{finite}$$

(A.7)

where the leading term in the symplectic density is $O(r^{-3} \ln^2 r)$. The divergent term of the variation of the action is,

$$\delta S_{div} \approx -\frac{1}{(p+1)!} \int \sqrt{h} \left( \ln r A_{ri}^{[\beta]} \delta A_{ri}^{p+1} \right)$$

(A.8)

which is again cured by the renormalization.

$n_p = 2$ The case $n_p = 2$ is a special case. This case has had already two independent normalizable modes in terms of $\psi$ and $\phi$ and the action is also finite and does not need renormalization. The symplectic form is also finite,

$$\Omega = \int \sqrt{q} d^n x^i drr^{-2} (1 - r^{-2} + \cdots) \delta (F_{ti}^{[\alpha]} + \cdots) \delta (A_{ri}^{p+1} + \cdots) \sim \text{finite}$$

(A.9)

where the leading term in the symplectic density is $O(r^{-2})$. 

\( n_p = 3 \) In this case the symplectic form and also the action diverge and it needs a renormalization. We explain in detail the renormalization of this case in detail which almost contains all the possible situations in a simple way. Considering the expansion of the gauge field as,

\[
A = (A^{[\alpha]} + A^{[\alpha,2]} r^{-2} \ln r + \cdots) + (A^{[\beta]} r^{-2} + \cdots)
\]  

(A.10)

where we suppressed the indices. Then from the equations of motion (2.5), in radial gauge we have,

\[
\left[ \frac{\hbar_p}{r} + \partial_r \right] \partial_r A_{\mu \nu}^{[\alpha,+1]} = \frac{r^{-4}}{4} \overline{D}^\mu F^{[\alpha]}_{\mu \nu} = 0
\]

(A.11)

where \( \overline{D}^\mu = \hbar^\mu \nu D_{\nu} \). This leads to,

\[
A_{\mu \nu}^{[\alpha,2]} = \frac{1}{2} D_{\nu} F^\mu_{[\alpha]} F^\nu_{[\alpha]}, \quad F^{[\alpha]}_{\mu \nu} \equiv (p + 2) D_{[\mu} A^{[\alpha]}_{\nu]}. 
\]

(A.12)

Now the variation of the action reads,

\[
\delta S \approx -\frac{1}{(p + 1)!} \int \sqrt{\hbar} \left( 1 - 2 \ln r \right) A_{[\alpha,2]}^{[\alpha]} \delta A_{[\alpha]}^{[\alpha,+1]} + 2 A_{[\beta]}^{[\alpha]} \delta A_{[\alpha]}^{[\alpha,+1]} \right) 
\]

(A.13)

which has the logarithmic divergence in the first term. As proposed in (3.6) the suitable counter-term action is,

\[
S_{ct} = \frac{1}{2(p + 1)!} \int d^p x^\mu \sqrt{\hbar} A_{[\alpha]}^{[\alpha,+1]} F^\mu_{[\alpha]} 
\]

(A.14)

which leads to,

\[
\delta S_{ren} \approx \frac{1}{(p + 1)!} \int \sqrt{\hbar} \left\{ \frac{2 \ln r - 1}{2} \left( A_{[\alpha,2]}^{[\alpha]} \delta A_{[\alpha]}^{[\alpha,+1]} - A_{[\alpha]}^{[\alpha]} \delta A_{[\alpha]}^{[\alpha,+1]} - A_{[\beta]}^{[\alpha]} \delta A_{[\alpha]}^{[\alpha,+1]} \right) + 2 A_{[\beta]}^{[\alpha]} \delta A_{[\alpha]}^{[\alpha,+1]} \right\} 
\]

(A.15)

Our goal here is to use the equation of motion (A.12) to rewrite the variation of the renormalized action as,

\[
\delta S_{ren} \approx \int \sqrt{\hbar} \partial^\mu \delta A_{[\alpha]}^{[\alpha,+1]} + \Theta 
\]

(A.16)

where \( \Theta \) is a finite term and all possible divergent terms are in \( \theta_{ct} \) which is a corner term. It is straightforward that using the equation of motion,

\[
\delta S_{ren} \approx \frac{1}{(p + 1)!} \int \sqrt{\hbar} \left\{ \frac{2 \ln r - 1}{4} D_{\mu} \left( F^\mu_{[\alpha]} \delta A_{[\alpha]}^{[\alpha,+1]} - A_{[\alpha]}^{[\alpha]} \delta F^\mu_{[\alpha]} \right) + 2 A_{[\beta]}^{[\alpha]} \delta A_{[\alpha]}^{[\alpha,+1]} \right\} 
\]

(A.17)

Where we can identify,

\[
\theta_{ct}^\mu = \frac{1}{(p + 1)!} \sqrt{\hbar} \left( \frac{2 \ln r - 1}{4} D_{\mu} \left( F^\mu_{[\alpha]} \delta A_{[\alpha]}^{[\alpha,+1]} - A_{[\alpha]}^{[\alpha]} \delta F^\mu_{[\alpha]} \right) \right) 
\]

(A.18)

\[
\Theta = \frac{1}{(p + 1)!} \sqrt{\hbar} 2 A_{[\beta]}^{[\alpha]} \delta A_{[\alpha]}^{[\alpha,+1]} 
\]

(A.19)

Now the symplectic form has the following expansion,

\[
\Omega = \int \sqrt{\hbar} d^p x^\mu d r r^{-1} \delta F^\mu_{[\alpha]} \delta A_{[\alpha]}^{[\alpha,+1]} + \text{finite} 
\]

(A.20)
where the leading term has logarithmic divergence. Then, it is then easily seen that the counter
term symplectic potential renormalizes the symplectic form by the relation,

\[ \Omega_{\text{ren}} = \int_{\Sigma} \omega' + \int_{\partial\Sigma_t} \omega_c^t \]  

(A.21)

where

\[ \omega_c^t = \frac{1}{(p+1)!} \sqrt{\hbar} \ln r \delta F_{\mu}^{\rho \mu + 1} \delta A^{[\alpha]}_{\rho \mu + 1} \]  

(A.22)

\( n_p = 4 \) This case is almost similar to the previous \( n_p = 3 \). The symplectic form is divergent,

\[ \Omega = \int \sqrt{\eta} d^d x^i dr \delta F_{\mu}^{[\alpha]} \right|_{t_{\rho \mu + 1}}^{\rho \mu + 1} \delta A^{[\alpha]}_{\rho \mu + 1} \]  

(A.23)

With renormalization one lead to,

\[ \theta_c^\mu = \frac{1}{(p+1)!} \sqrt{\hbar} \left( \frac{1}{2} F_{\mu}^{\rho \mu + 1} \delta A^{[\alpha]}_{\rho \mu + 1} - A^{[\alpha]}_{\rho \mu + 1} \delta F_{\mu}^{\rho \mu + 1} \right) \]  

(A.24)

which leads to a finite symplectic form.

\( n_p = 5 \) The same procedure is repeated here. Consider the fallow condition for the gauge field as,

\[ A = (A^{[\alpha]} + A^{[\alpha, 2]} r^{-2} + A^{[\alpha, 4]} r^{-4} \ln r + \cdots) + (A^{[\beta]} r^{-4} + \cdots) \]  

(A.25)

where from the equations of motion, we have,

\[ A^{[\alpha, 2]}_{\rho \mu + 1} = \frac{1}{4} D_\mu F_{\rho [\alpha]}^{\mu \rho + 1}, \quad A^{[\alpha, 4]}_{\rho \mu + 1} = \frac{1}{4} D_\mu F_{\rho [\alpha, 2]}^{\mu \rho + 1} - \frac{1}{4} D_\mu F_{\rho [\alpha]}^{\mu \rho + 1} \]  

(A.26)

Then we have

\[ \delta S_{\text{ren}} \approx \frac{1}{(p+1)!} \int \sqrt{\theta} r^2 \left( A^{[\alpha, 2]}_{\rho \mu + 1} \delta A^{[\alpha]}_{\rho \mu + 1} - A^{[\alpha]}_{\rho \mu + 1} \delta A^{[\rho \mu + 1]}_{\alpha, 2} \right) \]  

\[ + \frac{(1 - 4 \ln r)}{2} \left( A^{[\alpha]}_{\rho \mu + 1} \delta A^{[\rho \mu + 1]}_{\alpha, 2} - A^{[\alpha]}_{\rho \mu + 1} \delta A^{[\rho \mu + 1]}_{\alpha, 2} \right) + 4 A^{[\alpha]}_{\rho \mu + 1} \delta A^{[\rho \mu + 1]}_{\alpha, 2} \]  

(A.27)

where the symplectic form is,

\[ \Omega = \int \sqrt{\eta} d^d x^i dr \left\{ r \delta F_{\rho [\alpha]}^{[\alpha]} \delta A^{[\rho \mu + 1]}_{\alpha, 2} + r^{-1} \left( \delta F_{\rho [\alpha]}^{[\alpha, 2]} \delta A^{[\rho \mu + 1]}_{\alpha, 2} + \delta F_{\rho [\alpha]}^{[\alpha]} \delta A^{[\rho \mu + 1]}_{\alpha, 2} - \delta F_{\rho [\alpha]}^{[\alpha]} \delta A^{[\rho \mu + 1]}_{\alpha, 2} \right) \right\} + \text{finite} \]  

(A.28)

and using them we lead to,

\[ \theta_c^\mu = \frac{\sqrt{\theta}}{(p+1)!} \left\{ \frac{r^2}{4} \left( A^{[\alpha]}_{\rho \mu + 1} \delta F_{\rho [\alpha]}^{\rho \mu + 1} - F_{\rho [\alpha]}^{\rho \mu + 1} \delta A^{[\rho \mu + 1]}_{\alpha, 2} \right) \right\} \]  

\[ + \frac{(4 \ln r - 1)}{8} \left( \left( F_{\rho [\alpha, 2]}^{\rho \mu + 1} \delta A^{[\rho \mu + 1]}_{\alpha, 2} - A^{[\alpha]}_{\rho \mu + 1} \delta F_{\rho [\alpha]}^{\rho \mu + 1} \right) + \left( F_{\rho [\alpha]}^{\rho \mu + 1} \delta A^{[\rho \mu + 1]}_{\alpha, 2} - A^{[\alpha, 2]}_{\rho \mu + 1} \delta F_{\rho [\alpha]}^{\rho \mu + 1} \right) \right. \]  

\[ - \left( F_{\rho [\alpha]}^{\rho \mu + 1} \delta A^{[\rho \mu + 1]}_{\alpha, 2} - A^{[\alpha]}_{\rho \mu + 1} \delta F_{\rho [\alpha]}^{\rho \mu + 1} \right) \} \]  

(A.29)

This counter term cancels the divergent terms in the symplectic form, leading to a renormalized symplectic form.
$n_p > 5$ and $n_p < 0$ These cases can also be renormalized using the same method.

B Decomposition of the gauge field

Note that we have decomposed the gauge field in terms of the $p$-form and $(p+1)$-form components on the sphere. For the spherical components we then write,

\begin{equation}
A_{μν}^{[αι]} = _tab^{[αι]}_{p+1} + (p+1)D_{[μ}Φ_{ν]}p
\end{equation}

Where $tab$ is the co-exact $p + 1$-form component which is gauge invariant. Then we define,

\begin{equation}
A_{μν}^{[αι]} = A_{μν}^{[αι]} − δ_νΡ_{μ}^{p} \text{ which with previous decomposition we sum up as,}
\end{equation}

\begin{equation}
A_{μν}^{[αι]} = _tab^{[αι]}_{p+1} + (p+1)D_{[μ}Φ_{ν]}p
\end{equation}

where the temporal gauge fixing $Φ_{μ}^{p-1} = 0$, must be understood here. This gauge fixing is accessible by exact gauge transformation $δ_νΦ_{μ}^{p-1} = pδ_νc_{μ}^{p-1}$. Then we conclude that $tab$ is also gauge invariant. So the decomposition (B.2) can also be seen as decomposition to gauge invariant and pure gauge part. We can do the same decomposition for $A_{μν}^{[αι]}$. We write,

\begin{equation}
A_{μν}^{[αι]} = A_{μν}^{[αι]} + (p+1)D_{μ}Φ_{ν]+p}
\end{equation}

where again we have $Φ_{μ}^{p-1} = 0$. However note that in this case $A^{[αι]}$ is gauge invariant and then so $Φ$ and $A^{[αι]}$. The constraint equations are $D_{μ}A_{μν}^{[αι]} = 0$ so that

\begin{equation}
D_{μ}A_{μν}^{[αι]} = ∂_{ν}A_{μ}^{[αι]} + D_{μ}D_{[μ}Φ_{ν]}p = 0
\end{equation}

\begin{equation}
D_{κ}A_{κν}^{[αι]} = D_{κ}A_{κν}^{[αι]} − ∂_{κ}D_{κ}Φ_{κν}p = 0
\end{equation}

C The gauge independent part of $Θ$

Here we examine the flux term $Θ$. This leads to the symplectic flux for the gauge invariant sector $\tilde{ω} \sim δA_{μν}^{p-1}$ $δA_{μν}^{[αι]}$. The fact is that although we have two independent normalizable modes, we must choose one out of these two to have vanishing symplectic flux at least in the absence of $φ$ modes which is a pure gauge mode. The easy ones are, $δA^{[αι]} = 0$ or $δA^{[αι]} = 0$. However we have infinite continuous range of choices between these two when when we have two independent normalizable. This is the case for any $p$-form theory after renormalizing the symplectic structure. Here, following [39], if we want $\tilde{ω}$ to be vanished, we assume one of the following boundary conditions,

\begin{equation}
A_{μν}^{[αι]} = J_{μν}^{[αι]}(x, A^{[αι]}_{μν}+1) \text{ or } A_{μν}^{[αι]} = J_{μν}^{[αι]}(x, A^{[αι]}_{μν}+1)
\end{equation}

where, $J^{[αι]}$ and $J_{[αι]}$ are ultra-local functions of $A_{μν}^{[αι]}$ and $A_{μν}^{[αι]}$. Vanishing the symplectic flux then indicates the existence of the following potentials in each case,

\begin{equation}
J_{μν}^{[αι]} = (p+1)! δW_{μν}^{[αι]} c_{ρ}√h δA_{μν}^{[αι]} \text{ or } J_{μν}^{[αι]} = (p+1)! δW_{μν}^{[αι]} c_{ρ}√h δA_{μν}^{[αι]}
\end{equation}
Introducing these functions $W$ is to ensure that we have a well-defined action principle at least for this gauge invariant sector. We go on by introducing,

$$S_W = \int \mathcal{F} W$$  \hspace{1cm} (C.3)$$

Then one can show that,

$$\delta (S_{\text{ren}} + S_W) = \int \Theta \varphi$$  \hspace{1cm} (C.4)$$

So whenever we ignore the boundary gauge mode, by putting $\delta \varphi = 0$ leading to $\Theta \varphi = 0$, we have a well-defined action principle.

**D  Spherical Harmonics $p$-forms under Hodge duality**

Let us start by some basic definitions. Consider the inner product of $p$-forms on a compact $n$-manifold

$$\langle \alpha , \beta \rangle = \int_M \alpha \wedge \star \beta .$$  \hspace{1cm} (D.1)$$

The adjoint of the exterior derivative $d$ with respect to this inner product is called the co-differential operator $d^{\dagger}$, related to the exterior derivative by

$$d^{\dagger} = (-1)^{n(p+1)+1} \star \, d \, \star .$$  \hspace{1cm} (D.2)$$

The Laplace-Beltrami operator $\Delta$ is a second-order differential operator, mapping $p$-forms to $p$-forms

$$\Delta = dd^{\dagger} + d^{\dagger}d .$$  \hspace{1cm} (D.3)$$

A differential form $\alpha$ is called harmonic if $\Delta \alpha = d\alpha = d^{\dagger}\alpha = 0$. According to the Hodge decomposition theorem, any differential $p$-form on a closed Riemannian manifold can be decomposed into exact, co-exact and harmonic forms:

$$\omega_p = d\alpha_{p-1} + d^{\dagger}\beta_{p+1} + \gamma_p .$$  \hspace{1cm} (D.4)$$

The number of harmonic $p$-forms on $M$ is equal to the dimension of the $p$-th de Rham cohomology group $H^p_{\text{dR}}(M)$. Here we obtain the Hodge dual of $T_p$ $p$-forms in terms themselves which is useful to obtain the relations (5.4). This can be easily seen in form notation. First note that we have $\Delta \star = \star \Delta$. So $\star T_p$ is an eigen-form of $\Delta$ with the same eigen-value as $T_p$.

$$\Delta \star T_p^{(k)} = \star \Delta T_p^{(k)} = \star k^2_p T_p^{(k)} .$$  \hspace{1cm} (D.5)$$

Since we assumed that $T_p^{(k)}$ is an co-exact form, then $\star T_p^{(k)}$ is an exact $(n-p)$-form. So we can write,

$$\star T_p^{(k)} = c(k,p) dT_{n-p-1}^{(k)} .$$  \hspace{1cm} (D.6)$$

Note that we also have $\Delta d = d\Delta$. So the consistency implies that $k^2_p = k^2_{n-p-1}$ which can be checked independently. The factor $c(k,p)$ can also be fixed by normalization condition,

$$\langle \star T_p^{(k)} , \star T_p^{(k)} \rangle = c^2 \langle dT_{n-p-1}^{(k)} , dT_{n-p-1}^{(k)} \rangle = c^2 k^2_{n-p-1} = c^2 k^2_p = 1 .$$  \hspace{1cm} (D.7)$$

If $p = 0$, the kernel of $\star d$ is the constant function (being a harmonic form) for which $k = 0$ and it is dual to the volume form on the sphere.
