Regulated deficit irrigation and onion (*Allium cepa* L.) yield response on water productivity

Accepted 10th June 2021

ABSTRACT

Irrigation is the only solution to improve crop production and productivity thereby contributing towards food security, self-sufficiency and export market. The efficient use of water by irrigation system is becoming increasingly important in arid and semi-arid regions with limited water resources. The Experiment was conducted in DebreZeit Agricultural Research Center with the Regulated Deficit Irrigation and Onion (*Allium cepa* L.) Yield Response on Water Productivity in Ethiopia during 2017/2018 cropping season. The objective of the experiment was to identify the pin point of water stress threshold value of onion under deficit irrigation and investigate the effect of alternate, fixed and conventional furrow irrigation methods on crop yield and water productivity under deficit irrigation. The experimental treatments had three furrow irrigation methods, (alternate furrow irrigation (AFI), fixed furrow irrigation (FFI) and conventional furrow irrigation (CFI)) and two deficit irrigation levels of application, viz., 85% ETc and 70% ETc and a control irrigation of 100% ETc. The design of the experimental plot was split plot in RCBD arrangement and replicated three times. The three furrow irrigation methods were arranged as main plots and the deficit levels as sub plots. The experiment has a total of nine (9) treatment combinations. All collected data were statistically analyzed using SAS 9.1 statistical software. The experimental study result showed that bulb diameter, unmarketable bulb yield and total bulb yield of onion were highly significance difference (p<0.001) both in furrow irrigation methods and irrigation levels. Likewise diameter of onion also gave highest CFI and 100%ETc irrigation water application level which is 6.69 and 6.94 cm, respectively. According to the results obtained, the highest total yield was recorded for the treatment of 100%ETc irrigation water application and AFI of the furrow irrigation method 38947 and 35920 kg ha⁻¹, respectively. However, the lowest total bulb yield of 30253 and 29135 kg ha⁻¹ were recorded when FFI system was applied and in 70%ETc of water applied. Bulb height of onion was highly significance different (p<0.001) only on deficit irrigation levels. On the other hand, marketable bulb yield, irrigation water use efficiency and crop water use efficiency were significance different (P ≤ 0.05) by the interaction of furrow irrigation methods and deficit irrigation levels. The highest average marketable bulb yield of onion was obtained 42219 kg ha⁻¹ on CFI with the combination of 100%ETc irrigation level in addition to IWUE and CWUE, which both recorded highest result on 70%ETc and AFI furrow irrigation method. Generally, among all irrigation treatments 70%ETc deficit irrigation level applied under AFI method was efficient in conserving significant irrigation water. Therefore, it could be concluded that, AFI can save a substantial amount of water and labor without highly reduction of onion yield and the lowest CWUE and IWUE gave FFI followed by CFI.

Key words: Alternate furrow irrigation, conventional furrow irrigation, deficit irrigation, fixed furrow irrigation, onion.

INTRODUCTION

Food insecurity has been the problem of Ethiopia for many years and recurrent droughts have been one of the major problems during the past three decades. The occurrence of drought in most parts of the country is usually caused by insufficient rainfall to support the seasonal water requirements of the rain-fed crop production. About 80% of the country’s population is dependent on rain-fed agriculture and inadequate seasonal rainfall has caused serious food shortages that can adversely destabilize the social and economic life of the people (World Bank, 2006).
Irrigated agriculture makes a major contribution to food security, producing nearly 40% of food and agricultural commodities on 17% of agricultural land in the world. Irrigated areas have almost doubled in recent decades and contributed much to the growth in agricultural productivity over the last 50 years. Agriculture accounts for about 70% of the freshwater withdrawals in the world (FAO, 2013), while consumptive use of water in agriculture (water that is evaporated from irrigated fields) accounts for about 90% of all of the water that is evaporated as a result of human intervention. Irrigated agriculture is therefore the main reason for water demand and a driver of scarcity of fresh water in a number of regions.

In the 20th century, worldwide irrigated area experienced a huge expansion of more than 500% increase from 40 million to 270 million ha of irrigated land. Such numbers are part of the ability of humankind to produce food fast enough to meet population growth. But that remarkable ability, on the other hand, has its cost - a water crisis, characterized by water scarcity and competition, pollution and malnutrition (Molden, 2003).

Agriculture is the dominant sector in Ethiopian economy contributing about 45% to the gross domestic product (GDP) and 85% to export earnings. The cultivated land in the country is mostly rain-fed and subsequently variability of rainfall during the cropping season affects crop production and productivity. To solve such problems, irrigation is important. Irrigation not only improves crop production and productivity, but also reduces reliance on rainfall, contribute towards food security, self-sufficiency and export market.

Water availability is considered the climatic factor with greatest effect on agricultural productivity (Falkenmark and Rockstrom, 2000). Aranus et al. (2003) reported that, among the environmental factors affecting crops, the water input, expressed as the sum of rainfall and irrigation during the growing period, explained the large part of the yield variability.

Irrigation development is increasingly implemented in Ethiopia more than ever to supplement the rain-fed agriculture. It aims to increase agricultural productivity and diversify the production of food and raw materials for agroindustry as well as to ensure that the agriculture to play a pivotal for driving the economic development of the country (Mekonen, 2011). But, the overall performance of the crop production is still hindered due to unsustainable water supply. The scope for further irrigation development to meet food requirements in future is, however, severely constrained by decreasing water resources and growing competition for clean water. While on a global scale, water resources are still ample. Serious water shortages are developing in the arid and semi-arid regions, as existing water resources have reached full exploitation. The situation is exacerbated by the declining quality of water and soil resources. The dependency on water has become a critical constraint on further progress and threatens to slow down development, endangering food supplies and aggravating rural poverty. The great challenge for the coming decades will therefore be the task of increasing food production with less water, particularly in countries with limited water and land resources.

Water stress affects yield productivity in many ways. Most of the responses have a negative effect on production. But crops have different and often complex mechanisms to react to shortages of water. Several crops and genotypes have developed different degrees of drought tolerance, drought resistance or compensatory growth to deal with periods of stress. The highest crop productivity is achieved for high-yielding varieties with optimal water supply and high soil fertility levels, but under the conditions of limited water supply crops will adapt to water stress and can produce well with less water (FAO, 2002).

The use of fixed and alternate furrow irrigation methods allows for a reduction in volume irrigation water and completion of irrigation application in shorter time, thus reducing labor use when compared with conventional furrow irrigation method. Scientist observed a highly significant crop yield differences from alternate furrow relative to conventional furrow method (Kang et al., 1999).

Onion is one of the most cultivated vegetable crops in the world. It is produced in many countries both under rain fed and irrigation conditions. According to World Bank (2004) report in 2001, the crop shared one fourth of the vegetable export quantities and stood third following green beans and peas, contributing about 20% of the total vegetable export value which is about 244,000 US dollar of export earnings.

Global production of onions in 2008 was second only to tomatoes among horticultural crops: more than 73 million metric tons harvested from 3.6 million hectares. China alone produced more than 20 million metric tons; other leading producers were India, Australia, the United States, Pakistan, and Turkey (FAOSTAT, 2011). In Africa Egypt, Algeria, Morocco, Nigeria, South Africa and Niger are the leading producers of the crop in Africa (FAOSTAT, 2008). In Ethiopia, the crop is one of the most important vegetables produced by smallholder farmers mainly as a source of cash income and for flavoring the local stew ‘wot’ (Lemma and Shemelis, 2003; Fekadu et al., 2006). In 2016/17, the total area under onion production in Ethiopia is estimated to be 33603.39 ha with an average yield of about 97.45 Qt per ha (CSA, 2015/16).

The country has high potential to benefit from onion production. To attain the genetic potential yield and achieve high economic growth from onion production and productivity, it is necessary to study the response onion to different deficit irrigation levels and different furrow irrigation application methods. The experimental treatments had three furrow irrigation methods, viz., alternate furrow irrigation (AFI), fixed furrow irrigation (FFI) and conventional furrow irrigation (CFI) and three deficit irrigation levels of application, viz., 85% ETc, 70% ETc and 55% ETc, and a control irrigation of 100%ETc.
(Crop water requirement or crop evapotranspiration (ETc)).

The objective of the study was to investigate the effect of furrow irrigation methods and identify optimal deficit irrigation level on crop yield and water productivity of onion under central highland environment condition.

MATERIALS AND METHODS

Description of the study area

The Experiment was conducted in 2017/18 cropping season at DebreZeit Agricultural Research Center, main station about 47 km Southeastern of Addis Ababa. The geographical location extent ranges from $08^\circ 44' 15''$ to $08^\circ 46' 45''$ N Northern latitude and from $38^\circ 59' 45''$ to $39^\circ 01' 00''$ E Eastern longitude. The research center is located on a near level of a very gently sloping topography with a gradient of zero to 2% slope. It has low relief difference with altitude ranging from 1610 to 1908 m above the sea level. The site is situated in the Central high land area of the country having Tepid to cool sub-moist highlands type climate. The area receives an annual mean rainfall of 851 mm. The mean maximum and minimum temperature are 28.3 and 8.9°C, respectively with the average value of 19°C. The experimental fields are dominated by heavy soils (Vertisol) (WRB, 2014).

Soil samples were collected from experimental plots after irrigation for gravimetric soil moisture determination from different depths. Physical and Chemical properties of soil data: Soil texture, Bulk density, Field capacity (FC), permanent wilting point (PWP), electrical conductivity of soil (ECE), cation exchange capacity of soil (CEC), organic matter and soil pH, and the Chemical properties of irrigation water Electrical conductivity of irrigation water (ECw) and irrigation water PH were analysed.

The soil samples were analyzed at DebreZeit Agricultural research center’s soil laboratory for physical (texture, Field Capacity (FC), Permanent wilting Point (PWP)) and chemical quality (pH, Organic Matter (OM), Electrical Conductivity (EC) and Cat ion Exchange Capacity (CEC)) parameters at laboratory following standard test procedures. The FC and PWP were determined using pressure plate and membrane apparatus by applying a pressure of 0.33 bars and 15 bars, respectively, on saturate soil paste until no change in moisture is detected. The soil texture was analyzed using hydrometer method. The soil pH was determined by measuring soil solution of 1:2.5 ratios (soil to water) using a pH meter. The Organic carbon (%) was determined following the wet digestion method as described by Waldeley and Black (1934). OM content was then determined by multiplying OC by 1.724 (Nelson and Sommers, 1996). The ECE was determined by measuring the conductivity of saturated soil extract using electrical conductivity meter.

Onion seeds variety Nafis was used as seed material. The selected seed variety was sown in Oct 2017 on nursery bed. The seedlings were then transplanted in Dec 2017 on well prepared experimental plots and the seedlings were established in both sides of a ridge with row and plant spacing of 20 and 10 cm, respectively.

Cultural practices are dates of site selection, Land preparation, soil sampling, amount and frequency of pre irrigation, seedling preparation, transplanting, treatment application, crop management practice like wedding, cultivating and pesticide application, maturity and harvest recording of, Fertilizer Application time, crop growth length period and harvesting date.

Onion approaching maturity can simply be determined by 50% of its leaves dawn off harvested on the field. Marketable bulb yield (kg ha⁻¹) refers to yield of onions, which are not under sized (>5cm in diameter), free from physiological disordered and pest damaged bulbs. It was determined from weight of bulbs harvested from the net plot using digital balance.

Unmarketable bulb yield (kg ha⁻¹) refers to sized, color, physiologically disordered and pest damaged bulbs which was determined from weight of bulbs harvested from the net plot using digital balance (Moray et al., 2012). Onion bulbs with less than 5 cm diameter were categorized under unmarketable (Moray et al., 2012). The source of irrigation water in the study area is ground water with the depth of 60 m to irrigate the crop with the help of electric water pump.

Treatments and experimental design

The Experiment was conducted in 2017/18 cropping season at DebreZeit Agricultural Research Center. The experimental treatments had three furrow irrigation methods, viz., alternate furrow irrigation (AFI), fixed furrow irrigation (FFI) and conventional furrow irrigation (CFI) and two deficit irrigation levels of application, viz., 85 % ETc and 70 % Etc and a control irrigation of 100%ETc. Crop water requirement or crop evapotranspiration (ETc).

The design of the experimental plot was split plot in RCBD arrangement and replicated three times. The three furrow irrigation methods were arranged as main plots and the deficit levels as sub plots. The experiment had a total of nine (9) treatment combinations. The experimental field was divided into 27 plots with 3.6 by 4 m plot size to accommodate six furrows with spacing of 60cm having row and plant spacing of 20 and 10 cm, respectively. The plots and replications had a buffer zone of 2 m for canals carrying no irrigation water and 2.5 m for canals carrying irrigation water supply canals between plots with 3.6 m between plots. The experimental treatment combination is shown in Table 1.

Statistical analysis

The collected data were statistically analyzed
Table 1: Treatment combination.

| Sub-plot Irrigation Level | Main-plot - Furrow Irrigation Method |
|---------------------------|------------------------------------|
|                           | AFI  | FFI | CFI |
| 100% ETc                 | T1   | T4  | T7  |
| 85% ETc                  | T2   | T5  | T8  |
| 70% ETc                  | T3   | T6  | T9  |

appropriate to Split-plot design using statistical software which is Statistical Analysis System (SAS). Whenever the treatment effects were found significant, least significant difference (LSD) test was performed to assess any significant difference among treatments means.

RESULTS AND DISCUSSION

The different deficit irrigation levels under alternate, fixed and conventional furrow irrigation methods had shown a significant effect on onion bulb length and diameter, yield and yield components. The results are shown in sub-section below together with analysis of the experimental soil and climate characteristics.

Soil sampling and analysis

The results of soil analyses and field tests on physical and chemical characteristic are given in Table 2 and 3.

Soil physical characteristics

The laboratory analysis indicates that the basis particle size distribution in the soil was average value of 53.60% clay, 22.53% sand and 23.87% silt at experimental site. Therefore based on soil textural class determination triangle of international soil society (ISSS) system (Rowell, 1994) the soil of the experimental site was clay in texture. The bulk density of the experimental site showed slight variation with depth and varied from 1.04 to 1.15g/cm³. This could be because of slight decrease of organic matter with depth and compaction due to the weight of the overlying soil layer (Brady and Weil, 2002). The weighted bulk density (BD) and Total Available Water (TAW) of the experimental site are given in Table 2.

Soil chemical characteristics and water properties

Soil PH is an important parameter which measures hydrogen ion concentration in the soil to indicate its acidic and alkaline nature of the soil. According to Murphy (1968) rating scale, the pH value of the current experimental site soils was near to neutral (pH 7.07). Onion can grow well in soil pH range from 6.0 to 8.0 (Olani and Fikre, 2010).The soil had a Cation exchange capacity (12.77 meq/100g) through 60 cm profile and average electrical conductivity of (0.280ds/m) which is below the threshold value for onion yield reduction, that is, 1.2 dS/m (Smith et al., 2011).
Organic matter content (OM) improves water-holding capacity, nutrient release and soil structure. The OM content and OC content of the soil had average values of 1.80% and 1.05%, respectively which is rated as low. The findings of Tekalign (1991) who reported that soils having OM value in the range of 0.86-2.59% are considered low.

The laboratory result of the irrigation water showed the pH value of 7.47 and ECw value of 0.67 dS m⁻¹ (Table 3). According to Bryan et al. (2007), the irrigation water is classified in terms of pH as low (below 7), slight to moderate (7-8) and severe (above 8). Based on this classification, the characteristics of the irrigation water in the study area are found slight to moderate (Table 3).

Bauder et al. (2014), who reported that, irrigation water quality salinity hazard, has four categories: (≤ 0.75 dS m⁻¹ none), (0.76-1.5dS m⁻¹ some), (1.51-3.00 dS m⁻¹ moderate) and (≥3.00 dS m⁻¹ severe). Based on the above categories the irrigation water quality of the study area was classified at none.

**Crop water requirement and Irrigation water management**

The reference evapotranspiration ETo value of the experimental site ranged from 4.62 mm/day in December to 5.95 mm/day in March, with an average of 4.89 mm/day for the whole growth period. Using the reference evapotranspiration (ETo) and crop coefficient value (KC), calculation of the total seasonal onion crop water requirement or crop evapotranspiration (ETc) showed 436.14 mm (Table 4). This amount was needed for full irrigation level treatments (100%ETc). Accordingly, the 85%ETc and 70%ETc of irrigation level with the furrow irrigation methods of CFI were applied at 370.72 and 305.30 mm interval with AFI and FFI, as the same value of 100%ETc, 85%ETc and 70%ETc were 218.07 and 185.36 mm, respectively (Table 4). The Crop water requirement (ETc) values were low at the beginning of the initial growing season, increased gradually to maximum during development and mid stage and subsequently decreased based on crop growth stages and climate data (Table 5).

**Yield and yield parameters**

**Onion bulb diameter**

Onion bulb diameter was measured using digital caliper in centimeter to grade the quality of onion produced. The analysis of variance for bulb diameter showed a high significant (P<0.01) difference among furrow irrigation methods and also a high significant (P<0.01) difference among irrigation levels. The interaction of furrow irrigation methods and deficit irrigation level had no effect on onion bulb diameter (Table 6).

The CFI gave highest onion bulb diameter of (6.69 cm) and had no significant difference with AFI. The control irrigation (100%ETc) gave significantly higher onion bulb diameter that has no significant difference with deficit irrigation of (85%ETc) application. The smallest bulb size of (6.45 cm) was recorded from 70%ETc irrigation application and significantly inferior to all other irrigation levels. In a similar study, Demirtas and Serhat (2009) indicated that bulb diameter has increasing trend with increasing level of irrigation application.

**Onion bulb length**

The analysis of variance has shown that there was no significant difference among the different furrow irrigation methods and the interaction effect of furrow irrigation methods and deficit irrigation level on bulb length. Nevertheless, there was a highly significant (P<0.01) differences among the different irrigation levels on onion bulb length.

Significantly higher bulb length of (5.97 cm) was recorded from full irrigation (100%ETc) application and had no significant difference with deficit irrigation application of 85%ETc. The shortest bulb height was recorded from deficit irrigation application of 70%ETc. The result indicated that the 70% ETc deficit irrigation level might have reduced transpiration and photosynthesis and assimilate available for growth of the crop, which thus caused the production of small bulbs. This result is in line with that of Olalla et al. (2004) who observed smaller sized bulbs in mild water-stressed onion plants. Similarly, Neeraja et al. (1999) reported that higher level of irrigation 1.2 Irrigation Water (IW): Cumulative Pan Evaporation (CPE) resulted in maximum bulb length.

**Marketable bulb yield**

Marketable bulb yield are not under sized (>5cm in diameter), free from physiological disordered and pest damaged bulbs. Onion bulbs with greater than 5 cm diameter were categorized under marketable and less than 5cm diameter under unmarketable bulb yield (Moray et al., 2012). Analysis of variance showed that marketable bulb yield of onion was significantly affected (P<0.01) by the furrow irrigation methods and irrigation level. Similarly, interaction effect of furrow irrigation methods and irrigation level significantly (P<0.05) affected marketable bulb yield of onion.

The CFI practice with irrigation scheduled at the control (100%ETc) application gave significantly highest marketable bulb yield of (42219 kg ha⁻¹) (Table 7). This result seems closely related to that of Yemane et al. (2018), who reported that CFI methods with 100%ETc
Table 4: Irrigation interval, number and depth of irrigation.

| Treatments | Number of irrigation | Days between irrigation (interval) | Net Irrigation (In) (mm) | Gross Irrigation (Ig) (mm) |
|------------|----------------------|-----------------------------------|--------------------------|---------------------------|
| Furrow irrigation | Irrigation level (%) |                                  |                          |                           |
| CFI        | 100%                 | 19                                | 7                        | 436.14                    | 726.9                    |
|            | 85%                  | 19                                | 7                        | 370.72                    | 617.9                    |

The analysis of variance has shown that unmarketable bulb yield was not significantly affected by interaction effect of furrow irrigation methods and irrigation levels. Furrow irrigation methods and irrigation levels had a highly significant ($P<0.001$) influence on unmarketable bulb yield (Table 8).

**Unmarketable bulb yield**

The analysis of variance has shown that unmarketable bulb yield was obtained from FFI and 70%ETc and 85%ETc under the CFI and the AFI practices have shown no significant difference on marketable bulb yield. Generally, among the furrow irrigation methods, CFI and AFI produced the best marketable bulb yield and while significantly lowest mean marketable bulb yield were obtained from FFI and 70%ETc application.

Yemane et al. (2018) reported that small amount of applied water reduced yield in every other furrow irrigation (AFI and FFI) as compared with CFI due to water stress, when the same irrigation frequency was applied which supported the result of this study.

The present result agreed with the general principle that the response of crop to full irrigation is generally higher under irrigated conditions than none irrigated one (Michael, 1978). Similar to the present observation, Patel and Rajput (2013) also reported that water application with no deficit (100% full Crop water requirements) at any stage of plant growth gave highest marketable yield. De santa et al. (1994), Neeraja et al. (1999) and Bosch sera and Currah (2002) also showed that marketable bulb yield of onion increased with increasing irrigation water amount in a linear fashion.

Similar results were also reported by Kloss et al. (2012) who showed that dealing with improvement of water productivity is closely related to the irrigation practice of regulated deficit irrigation and has a direct effect on yield, that is, if the amount of water applied decreases, similarly the crop yield will also drop.

The CFI gave the lowest unmarketable bulb yield and was not significantly different from AFI. The control irrigation (100%ETc) also had the lowest unmarketable bulb yield and among the deficit irrigation levels, the 85%ETc application gave significantly lowest unmarketable bulb yield. Moreover, the highest unmarketable bulb yields were recorded from the FFI practice and deficit irrigation application of 70%ETc.

Stressed onion plants may bulb too early, produce small-sized bulbs and high amount of unmarketable yield (Kebede, 2003). This could be due to low rate of transpiration caused by stomata closer under moisture stress condition which brought about reduced photosynthesis and poor bulb growth and developments. Corresponding to this, Martin et al. (2004), Olalla et al. (2004) and Zayton (2007) reported that plots which received the lowest amount of water during the development and maturing stages produced higher percentage of small size bulbs. From present result, increasing water deficit had a positive relationship with the production of high yield of under size bulbs.

**Total bulb yield**

The total bulb yield is the sum of unmarketable and marketable bulb yield. The furrow irrigation method and irrigation level have shown a highly significance ($P<0.01$) difference on total bulb yield (Table 8). The analysis of variance has shown that unmarketable bulb yield was not significantly affected by interaction effect of furrow irrigation method and irrigation level.

The AFI gave the maximum total bulb yield of (35920kg ha$^{-1}$) and had no significant difference with CFI practice. In fact significantly highest bulb yield was obtained from the control irrigation (100%ETc). However, from deficit irrigation levels, the 85%ETc application gave the highest total bulb yield and significantly different from all other deficit irrigation levels. Significantly lowest total bulb yield was obtained from the FFI practice and from deficit

Means in a Column with the same superscripts are not significantly different at $P \geq 0.05$. 

- CFI: Centered furrow irrigation
- AFI: Alternating furrow irrigation
- FFI: Full furrow irrigation
Yield by application of P<0.05 kg m

When irrigation methods and irrigation levels on IW were converted to 100% ETc, the total bulb yield increased. The increment in onion total bulb yield might be attributed to large size of onion bulb due to application of maximum amount irrigation water. This is because it encourages cell elongation, above ground vegetative growth and imparts dark green color of leaves, which is important for more assimilate production and partition that favors onion bulb growth. Crops irrigated under AFI physiologically respond to the water stress by producing signals to control the leaf water potential, so that transpiration loss can be significantly reduced (Kang et al., 2000).

The increased total bulb yield by application of full irrigation could have better performance on vegetative growth like plant height, number of leaves and leaf length which increase photosynthetic capacity of the plant, which in turn can improve bulb weight and contribute to increment in total bulb yield. As the irrigation level increased from 70% ETc to 100% ETc, the total bulb yield increased.

**Irrigation level and furrow irrigation methods on IWUE and CWUE**

**Irrigation water use efficiency**

Irrigation water use efficiency (IWUE) is considered as relative bulb yield per unit of irrigation water used. The analysis of variance has shown that the interaction of furrow irrigation methods and deficit irrigation levels significantly (P<0.05) affected IWUE and whilst a highly significant (P<0.01) effect was observed from furrow irrigation methods and irrigation levels on IWUE (Table 9). The highest IWUE of (12.62 kg m⁻³) was recorded from AFI practice with the 70%ETc deficit irrigation application and significantly different from all other treatments. The AFI practice gave best IWUE as compared with other furrow irrigation methods. The lowest irrigation water use efficiency of (5.58 kgm⁻³) was obtained from CFI practice with 85%ETc deficit irrigation application and had no significant difference with control irrigation (100%ETc) application under CFI practices.

Generally, IWUE was influenced by crop yield potential, irrigation method, estimation and measurement of ET, and crop environment. The results related to the efficiencies showed that when irrigation water is limited, 70% deficit irrigation can be applied by increasing the water use efficiency. Mansouri-Far et al. (2010) reported that irrigation water can be conserved and yields maintained (as sensitive crop to drought stress) under water limited conditions.

**Crop water use efficiency**

The crop water use efficiency (CWUE) in the study measures the effectiveness of the irrigation levels and furrow irrigation methods in converting the total water applied to onion bulb yield. The analysis of variance has shown that the interaction of furrow irrigation methods and deficit irrigation levels significantly (P<0.05) affected CWUE and whilst a highly significant (P<0.01) effect was observed from furrow irrigation methods and irrigation levels on CWUE (Table 10).

As shown in Table 10, the highest CWUE of (17.91 kg m⁻³) was achieved with 70%ETc deficit irrigation application with AFI practice and this was significantly different from the CWUE in all treatment combinations. All deficit levels with AFI and CFI systems attained, respectively, the highest and lowest CWUE. The results of these research findings are in agreement with that of Hamed et al. (2011), who reported that the reason for obtaining more CWUE and

Note: Eta: Actual Evapotranspiration; ETm: Maximum Evapotranspiration; Ya: Actual Yield; Ym: Maximum Yield; Ky: Yield Response Factor.

lower reduction in the yield for AFI could be related to better distribution of the roots in both sides of the ridge. It could increase water and fertilizer uptakes by plants. The results showed that alternative drying of the root zone had better performance than the fixed drying of the root zone. The results showed that AFI increased CWUE for onion relative to CFI.

In line with this result, Samson and Ketema (2007) reported that deficit irrigations increased the water use efficiency of onion. Similarly, Shock et al. (1998), Kebede (2003), Kirnak et al. (2005) and Sarkar et al. (2008) reported that crop water use efficiency was higher at lower levels of available soil moisture.

**Onion bulb yield response to deficit irrigation**

The response of onion yield to water supply as quantified through yield response factor (Ky) is shown in (Table 11). The Ky ranged from 0.15 to 1.16, where both the lowest and the highest being from 85%ETc application under AFI and CFI, respectively. Generally, it can be observed that Ky

Kirida C, Kamber B (1999). Water, no longer a plentiful resource, should be used sparingly in irrigated agriculture. In: Kirda C. P.,Moutonnet ,Hera C. and Nielsen D.R., eds. Crop yield response to deficit irrigation. Kluwer Academic Publishers. Dordrecht. The

decreased with decreasing onion bulb yield and increasing irrigation water deficit. The crop yield response factor (Ky) captures the essence of the complex linkages between production and water use by a crop. Crop yield response factor indicates a linear relationship between the decrease in relative water consumption and the decrease in relative yield. The ky values greater than unity indicates that the relative yield decrease is higher than the water deficit as stated by Smith and Kivumb (2002). According to Kirda et al. (1999), the ky value for field crops goes from 0.2 to 1.15 which is in line with the reported result.

Doorenbos and Kassam (1979) reported the effect of water deficit on crop yield, deficit occurring for the total growing period, as the decrease in yield is proportionally less with the increase in water deficit. Under conditions of limited water distributed equally over the total growing season, involving crops with different Ky values, the crop with the higher Ky value will suffer a greater yield loss than the crop with a lower Ky value.

CONCLUSION

Based on the result arisen from the research when less irrigation water was applied, the conventional furrow irrigation techniques had the smallest bulb yield reduction. The maximum total bulb yield of (35920 kg ha⁻¹) was recorded at Alternative Furrow Irrigation Method. Although 70%ETc application under alternate furrow irrigation gave the highest Crop Water Use Efficiency and Irrigation Water Use Efficiency, yield penalty was significant as compared with all other deficit irrigation. However, deficit irrigation of 70%ETc under alternate furrow irrigation gave above the mean value of crop water use efficiency and irrigation use efficiency. The most important finding of the present study is that water under deficit irrigation with the combination of Alternative Furrow Irrigation (AFI) is a promising practice that can be adopted as alternative for irrigating intensive field crop like Onion; but more studies need to be conducted under similar field conditions.

ACKNOWLEDGMENTS

The author would like to thank Ethiopian Institute of Agricultural Research, for providing funds for the experiment and technical support for masters of Thesis. Also the author is very grateful to DebreZeit Agricultural research center for all staff of Natural Resources Management Research core process and friends for providing support in field management, suggestion and technical guidance during the course of the experiment. Additionally, Hawassa University Institute of Technology Water Resource and Irrigation Engineering Department Lecturers and Staffs are gratefully acknowledged for their support in my master’s course.
