ABSTRACT

Purpose: To report the 12-month efficacy and safety outcomes of intravitreal ziv-afiblercept in macular edema secondary to central retinal vein occlusion (CRVO).

Methods: Intervventional case series documenting 12-month outcomes of intravitreal ziv-afiblercept (1.25 mg in 0.05 mL) in 6 patients with treatment-naïve macular edema secondary to CRVO. All patients had comprehensive ophthalmic examination, spectral domain optical coherence tomography at baseline and all follow-up visits, and fluorescein. Retreatment decisions were based on recurrence or persistence of intraretinal or subretinal fluid, deterioration in visual acuity (VA), increase in central subfield thickness (CST) by \( \geq 50 \mu \text{m} \) from the previous visit, or lowest recorded CST.

Results: Participants had (2 males, 4 females) an average age of 53.5 years. From baseline to 12 months, the mean logMAR VA improved from 0.86 (Snellen \( 20/145 \)) to 0.33 (Snellen \( 20/40 \)), central macular thickness decreased from 519 \( \mu \text{m} \) to 255 \( \mu \text{m} \), and total macular volume decreased from 14.7 mm\(^3\) to 7.1 mm\(^3\). No eyes had uveitis, cataract progression, intraocular pressure (IOP) elevations, or systemic adverse events.

Conclusions and importance: Ziv-afiblercept achieves favorable intermediate-term functional and structural outcomes in macular edema secondary to CRVO. No safety concerns were raised. Low-cost ziv-afiblercept may thus be useful for CRVO in resource-poor countries. Further prospective studies in larger cohorts are needed further establish the efficacy and safety of this agent.

1. Introduction

Central retinal vein occlusion (CRVO), is a common cause of vision loss affecting an estimated 2.5 million people globally.\textsuperscript{1} A key pathogenic mechanism of retinal ischemia consequent to venous occlusion involves the upregulation of hypoxia regulated genes, including vascular endothelial growth factor-A (VEGF-A), a primary mediator in CRVO-associated macular edema.\textsuperscript{2,4} The most common cause of visual impairment in patients with CRVO is macular edema.\textsuperscript{5}

Over the last 3 decades, significant improvements in visual acuity (VA) outcomes for macular edema secondary to CRVO have been achieved owing to the advent of novel pharmacologic therapeutic modalities. Intravitreal steroid injections were the initial standard of care for CRVO-associated macular edema owing to the results of the SCORE and GENEVA trials.\textsuperscript{6,7} However, the current mainstay of treatment is intravitreal anti-VEGF agents. One of these is afiblercept (Eylea; Regeneron Pharmaceuticals, Inc., Tarrytown, NY), which showed excellent functional and structural outcomes.\textsuperscript{8,9}

Ziv-afiblercept (Zaltrap; Regeneron, New York, USA) is structurally isomeric with afiblercept, and acts on all VEGF subtypes, as well as placental growth factor. It is currently FDA-approved for metastatic colorectal cancer,\textsuperscript{10} and is thus potentially available for ocular use by compounding pharmacies at a much lower cost than afiblercept. Intravitreal ziv-afiblercept has been used in a single patient with treatment-naïve branch retinal vein occlusion (BRVO), with favorable visual and structural response, and no signs of retinal toxicity or any ocular adverse events.\textsuperscript{11} Similar findings were noted in treatment-resistant patients with BRVO.\textsuperscript{12} Currently, there are no reports on the intermediate-term outcomes and safety of ziv-afiblercept in treatment-naïve CRVO, which would be important for further studies investigating a broader use of this agent. We report its use in 6 consecutive patients using a pro re nata (PRN) schedule.

Table 2
Baseline and one-year clinical and optical coherence tomography characteristics.

| Variable                             | Baseline (n = 6) | 12 months (n = 6) | P-value |
|--------------------------------------|------------------|-------------------|---------|
| logMAR VA, mean ± SD (range)         | 0.86 ± 0.25 (0.54-1.20) | 0.33 ± 0.22 (0.09-0.69) | 0.007   |
| CST, mean ± SD (range), μm            | 519 ± 137 (325-708) | 255 ± 27 (229-298) | 0.008   |
| Total Macular Volume, mean ± SD (range), mm³ | 14.7 ± 3.9 (9.2-19.8) | 7.1 ± 0.8 (6.3-8.2) | 0.007   |
| IOP, mean ± SD (range), mm Hg        | 18.3 ± 3.6 (13-22) | 17.5 ± 2.3 (14-20) | 0.55    |

2. Methods

2.1. Study design and subjects

This was a prospective single-center interventional case series conducted at Rafic Hariri University Hospital, Lebanon, between January 2015 and July 2016. This study was approved by the institutional review board and ethics committee, and adhered to the tenets of the Declaration of Helsinki. Informed consent was also obtained from patients.

Six treatment-naïve patients with CRVO and macular edema were included. Inclusion criteria included age ≥18 years and VA between ≤20/40 and ≥20/320. Exclusion criteria included previous treatment with intravitreal steroids or other anti-VEGF agents, laser photocoagulation, intraocular pressure (IOP) ≥25 mm Hg, iris neovascularization, coexisting ocular conditions affecting VA, and poor-quality spectral domain optical coherence tomography (SDOCT) scans.

2.2. Patient evaluation

At each follow up visit, best corrected visual acuity (BCVA) assessment with Snellen charts, slit lamp and dilated fundus examinations, and SDOCT (Cirrus; Carl Zeiss Meditec, Dublin, California, USA) macula scans, were performed. The participants were treated with 0.05 mL ziv-afibercept (1.25 mg) at baseline, followed monthly, and managed on a pro re nata (PRN) protocol for at least 12 months. Retreatment criteria included recurrence or persistence of intraretinal or subretinal fluid, deterioration in VA by Snellen equivalent of 1 ETDRS line, increase in central subfield thickness (CST) by ≥50 μm from the previous visit or the lowest recorded CST. Fluorescein angiography was performed for all cases to detect significant ischemia requiring panretinal photocoagulation (PRP), i.e., more than 10 disc diameters of capillary non-perfusion.

The primary outcomes were changes in BCVA, CST, and total macular volume from baseline to the 12-month visit. Secondary outcomes were the number of injections received, and incidence of intraocular side effects (including cataract progression, ocular inflammation, and increase in IOP). The occurrence of systemic adverse events, including nasopharyngitis, headaches, hypertension, cardiovascular events, cerebrovascular accidents, if any, were noted.

2.3. Statistical analysis

Statistical analyses were conducted with SPSS V.22 (IBM Corporation, Chicago, Illinois, USA). Snellen VA readings were converted into logarithm of the minimum angle of resolution (logMAR) VA values. P-values were generated using paired t-tests comparing baseline and the 1-year outcomes.

3. Results

All eyes were phakic (3 with mild cataracts). Patients (4 females and 2 males) had an average age of 53.5 ± 7.23 years (range, 44-65). Three patients had systemic hypertension (50%), 4 patients had diabetes (66.7%) and only 1 patient was a smoker (16.7%). Demographic and clinical characteristics are shown in Table 1.

The mean logMAR BCVA improved by 0.53 ± 0.30 from baseline 0.86 ± 0.25 (Snellen equivalent = 20/145) to 0.33 ± 0.22 (Snellen equivalent = 20/40) at the 12-month visit (p = 0.007), equivalent to gaining +26.5 letters on the ETDRS scale. The mean CST decreased from 519 ± 137 μm at baseline to 255 ± 27 μm at 12 months (p = 0.008). Similarly, the total macular volume decreased from 14.7 ± 3.9 mm³ at baseline to 7.1 ± 0.8 mm³ at 12 months (p = 0.007). During this period, study participants received an average of 6.2 ± 1.2 injections (range 5–8 injections). IOP remained stable between baseline (18.3 mmHg) and 12-month visits (17.5 mmHg) (p = 0.55) (Table 2). No eyes had significant capillary non-perfusion requiring PRP. Structural response to ziv-afibercept treatment is illustrated in Fig. 1.

No signs of intraocular inflammation, cataract progression, or systemic side effects were detected or reported by patients at all follow-up visits.

4. Discussion

Ziv-afibercept achieves promising structural and VA outcomes at 1 year in treatment-naïve CRVO-associated macular edema, comparable to that obtained with fixed-dosing regimens of anti-VEGF agents. In this series, 1.25 mg of ziv-afibercept dosed PRN achieved a mean VA gain of +26.5 letters and a CST decrease of 264 ± 151 μm over a treatment interval of 12 months. No safety concerns were raised in this pilot study. In the COPERNICUS and GALILEO trials involving fixed monthly injections of afibercept in CRVO, 2 mg of afibercept achieved an
average of +17.8 and +18 letters gained, respectively. These trials achieved mean CST reductions from baseline to 12 months of 457.2 μm and 448.6 μm, respectively. Caution should be applied in these comparisons, as our study involved a small sample of only 6 patients. However, the younger age profile and earlier presentation could explain the better VA gains in our population.

The patients in our series did not develop any adverse ocular effects of increased inflammation or IOP. Initial ocular safety concerns arose based on in-vitro studies showing mitochondrial toxicity on human retinal pigment epithelial (RPE) cells with ziv-aflibercept and bev-azimab, but not for aflibercept and ranibizumab. No further studies were conducted using electro-oculogram on eyes injected with ziv-aflibercept, so its effect on the RPE in vivo remains unknown. Additionally, electroretinogram (ERG) analysis in a small group of patients with wet age-related macular degeneration (AMD) and diabetic macular edema (DME) demonstrated no alterations through 6 months of ziv-aflibercept therapy. No ERG changes were reported in a single case of BRVO treated with ziv-aflibercept for 3 months. A second concern arose owing to an osmolality difference between the different buffers used. Ziv-aflibercept has an osmolality of 1000 mOsm/kg (hyperosmotic due to the addition of sucrose), while aflibercept has an osmolality of 300 mOsm/kg (isosmotic to vitreous fluid). However, it is estimated that a 0.05 mL aliquot injection of 1000 mOsm/kg ziv-aflibercept would modestly increase vitreous cavity osmolality by only 4%, thus still registering within normal physiological limits. Our study also provides support for the intermediate-term systemic safety of ziv-aflibercept in CRVO. Short-term systemic safety has been documented by the absence of systemic effects in patients with wet
AM, DME, and BRVO. Of note, no systemic safety issues with aflibercept in CRVO have been raised in the COPERNICUS and GALILEO trials to date. This is despite pharmacokinetic studies after a single aflibercept injection showing higher circulating systemic levels of aflibercept, which were 5-fold (peak level), 37-fold (trough level) and 9-fold higher (area under the curve) than ranibizumab. Aflibercept was also found to suppress circulating plasma-free VEGF, with mean levels below the lower limit of quantitation from 3 h after administration, and lasting ≥7 days. Studies with a longer follow-up interval in a larger patient cohort is indicated to further establish the systemic safety of ziv-aflibercept.

The compounded ziv-aflibercept drug appeared to be stable for 4 weeks as indirectly demonstrated by good clinical response in this series. VEGF assays also demonstrated no loss of VEGF blockade with use of ziv-aflibercept which had been stored for 1 month.

Bevacizumab is currently the most cost-effective treatment for macular edema secondary to CRVO. Likewise, the low cost of ziv-aflibercept would likely make it an attractive option in resource-poor countries. The actual compounded cost is approximately 30 times less for ziv-aflibercept than for aflibercept. Thus, if the 4 mL ziv-aflibercept vial is divided into 40 aliquots of 0.05 mL (1.25 mg of ziv-aflibercept), the approximate cost of each aliquot would be US $25, which is significantly lower than a single Eylea® vial costing US $700 in Lebanon. Extrapolated over the course of multiple injections in CRVO, this would translate into considerable monetary savings.

Limitations of this study include the small sample size and one-armed open label design. No electrophysiologic information was available to ascertain local toxicity. Despite this, our study provides satisfactory initial data on the intermediate-term efficacy and safety of PRN ziv-aflibercept in eyes with macular edema due to CRVO.

5. Conclusion

Off-label use of PRN ziv-aflibercept over a 12-month period demonstrates good structural and functional outcomes for macular edema secondary to CRVO, without evident ocular or systemic adverse events. Low-cost ziv-aflibercept may potentially be a viable substitute for aflibercept, particularly in countries where aflibercept is unavailable, and in resource-poor regions. Larger studies are warranted to confirm our findings.
