TWO-DIMENSIONAL ELASTIC THEORY METHODS FOR DESCRIBING
THE STRESS STATE AND THE MODES OF ELASTIC BORING

Purpose. To find the stressed state and describe the operating regimes of an important element of mining industrial equipment — an elastic drilling bit — based on the method of finding the solutions of problems of solid mechanics using holomorphic functions of two complex variables.

Methodology. Methods for constructing the basic solutions of three-dimensional boundary value problems of the theory of elasticity are based on the representation of the fundamental solutions of the Lamé equations in the Papkovich–Neuber form using a scalar spatial harmonic function and a vector spatial harmonic function. This made it possible to formulate the boundary value problem in terms of holomorphic functions of complex variables. Based on the representation of the above holomorphic functions in the form polynomial of the $n$th order in accordance with degrees of the complex variables, corresponding boundary conditions are formulated for basic solutions and integral conditions for the principle moment of the stress vector on the lateral surface being equal to zero are additionally specified.

Findings. The paper formulates complex-conjugate boundary value problems of spatial theory of elasticity in terms of holomorphic functions of two complex variables. We have considered the case when there is one of the spatial coordinates on which the stress tensor does not depend on, for a body whose surface is described by standard curves. For the given finite elastic cylindrical solid (a drilling bit) of canonical cross-section, a set of the basic complex solutions of the $n$th order and of corresponding vectors of external loads has been constructed.

Originality. For the first time, a scheme and a method for constructing the basic solutions of static boundary value problems of spatial theory of elasticity have been suggested and the corresponding boundary conditions have been imposed; the real and imaginary parts of the solutions of the boundary value problems for a cylindrical drilling bit have been constructed and an analysis of these solutions has been carried out.

Practical value. An example of using the developed methods for constructing solutions of boundary value problems of spatial theory of elasticity has been considered for finding an exact analytical solution of a two-dimensional boundary value problem that describes the distribution of stresses and corresponding external loads on the lateral surface of a cylindrical drilling bit of a canonical cross-section. Such mathematical models and analysis of the external load structure can be effectively used to describe the safe operating modes of mining boring equipment.

Keywords: theory of elasticity, stress tensor, displacement vector, external load vector, holomorphic function

Introduction. Literature review. One of the main scientific directions of the study on boundary value problems of mechanics of a deformable solid is the spatial problems of the theory of elasticity. For fundamental and applied research studies, the relevance of this topic is determined by the fact that almost always a stress-strain state of a body is of three-dimensional character. Approaches of mechanics of a deformable solid are basic for calculating and evaluating the parameters of strength and reliability of elements of engineering structures and devices that are under the influence of external force load. A great deal of scientific monographs and publications, in particular, the classical works by S. Tymoshenko, J.N. Goodier, and A. Lurie, are devoted to the formulation of boundary value problems of the theory of elasticity and to the development of their research methods. At present, numerical [1], qualitative [2, 3] and analytical [4, 5] approaches to constructing the solutions of boundary value problems of dynamic and static theory of elasticity have been developed.

The Fourier method, the potential method, and the method of theory of functions of a complex variable made it possible to substantiate the correct formulation of the basic boundary value problems of the theory of elasticity. Moreover, in some cases, these methods allowed us to construct spatial static and dynamic problems for canonical domains. In recent decades, experimental [6, 7] and approximate [8, 9] approaches to solving boundary value problems of the theory of elasticity have been actively developing.

The methods for solving spatial problems of static theory of elasticity known from literature are based on representing solutions of the homogeneous equations of equilibrium in terms of displacements using harmonic and biharmonic functions. In the case of a plane static problem of the theory of elasticity of an isotropic body, the general integral of the equations of equilibrium is represented in terms of a biharmonic function.

In the classical papers by Muskhelishvili, for the first time the stress tensor and the displacement vector were represented through the analytic functions of a complex variable. These representations were rigorously substantiated for the case of a multiply-connected domain, and appropriate methods were developed for solving the plane problems of the theory of elasticity. Important results concerning application of a mathematical apparatus of functions of a complex variable are also used when considering the spatial problems of the theory of elasticity. The representation of solutions of the basic equations in the form of integral operators of analytical functions of a complex variable and the variant of formulation of the problem of spatial theory of elasticity with the use of functions of two complex variables, which are introduced in the four-dimensional space of real variables, have been suggested. Three-dimensional problems of the theory of elasticity are considered as some partial class of the problems of the four-dimensional theory of elasticity. The equilibrium equations in terms of displacements for a four-dimensional elastic medium in the absence of bulk forces are represented by the equations

\[
(\lambda + \mu) \frac{\partial^2 \theta}{\partial x_i^2} + \mu \Delta \theta_i = 0; \quad \theta = \frac{\partial \Psi}{\partial x_i}, \quad i = 1, 4,
\]

The paper formulates complex-conjugate boundary value problems of spatial theory of elasticity in terms of holomorphic functions of two complex variables. Based on the representation of the above holomorphic functions in the form polynomial of the $n$th order in accordance with degrees of the complex variables, corresponding boundary conditions are formulated for basic solutions and integral conditions for the principle moment of the stress vector on the lateral surface being equal to zero are additionally specified.

where $\vec{u} = u_i \hat{e}_i$ is the displacement vector, $l$, $\mu$ are the Lame parameters, $\Delta = \frac{\partial^2}{\partial x^2}$ is the Laplace operator $(i=1,4)$. There is considered a class of solutions of such equations which are determined by the equality

$$\theta = \frac{\partial u_i}{\partial x_4} = 0. \ (i=1,4).$$

For the class of solutions determined in this way, the constitutive equation of equilibrium is broken down into three equations of equilibrium of the three-dimensional theory of elasticity and the Laplace equation for the function $u_i(x_1, x_3, x_4)$. The integral functions of displacements and the complex variables are introduced

$$W_1 = u_1 + i u_4; \quad W_2 = u_1 + i u_3; \quad z_1 = x_1 + i x_3; \quad z_2 = x_1 + i x_4.$$

As a result, the constitutive equations of equilibrium take the following form

$$\lambda \frac{\partial u_1}{\partial x_3} + 2\mu \frac{\partial^2 W_1}{\partial z_1 \partial z_3} + 2\mu \frac{\partial^2 W_1}{\partial z_2^2} = 0; \quad \lambda \frac{\partial u_2}{\partial x_3} + 2\mu \frac{\partial^2 W_2}{\partial z_1 \partial z_2} + 2\mu \frac{\partial^2 W_2}{\partial z_2^2} = 0; \quad \lambda \frac{\partial u_1}{\partial x_3} + 2\mu \frac{\partial^2 W_1}{\partial z_1 \partial z_2} + 2\mu \frac{\partial^2 W_1}{\partial z_2^2} = 0.$$

The solution of the constructed equations can be obtained in terms of two arbitrary holomorphic functions $\Phi(z_1, z_2)$, $\Psi(z_1, z_2)$ in the form of formal series

$$W_i = \sum_{m=0}^{\infty} \frac{(-1)^m}{m!} \Phi(z_1, z_2) \frac{\partial^m}{\partial z_2^m} f(z_1, z_2) + \frac{m}{4(1-\nu)} \Phi(z_1, z_2) + (\nu - 1) \frac{\partial^m}{\partial z_2^m} f(z_1, z_2) \times \sum_{k=0}^{\infty} \frac{(-1)^k m^{k+1}}{4(1-\nu)k!} \frac{\partial^{m+k}}{\partial z_2^{m+k}} f(z_1, z_2),$$

where $l = 2m + n$, $k = 2 - n$, $i=1,2$. Here $J$ is the operator inverse to the operator $\frac{\partial}{\partial x_4}$. To determine the holomorphic functions $\Phi(z_1, z_2)$ and $\Psi(z_1, z_2)$, like in the case of a plane problem of the theory of elasticity, we can use either their integral representations in terms of their boundary values or their series expansion in terms of a complete system of holomorphic functions in a two-dimensional complex domain.

In the papers [10, 11], by means of the method of complex potentials the spatial contact problems of thermoelastic behavior of bimaterial bodies with heat-permeable interphase frictions under thermal and force loads are solved, as well as the problems of interaction of bodies with surface inhomogeneities.

A mathematical body of the theory of functions of a complex variable is widely used for constructing solutions of boundary value problems of theory of plastic deformation [12], fracture mechanics for piezoelectric solids [13, 14], piezoceramic solids [15], and bimaterials [16] with interfacial cracks under the action of mechanical loads, electromagnetic and thermal fields [17, 18].

In this paper, the boundary value problem of a two-dimensional theory of elasticity in terms of the holomorphic functions $G_1(z_1, z_2)$, $G_2(z_1, z_2)$ has been considered, provided that the stress tensor does not depend on one of the spatial variables for a finite cylindrical elastic drill geometrically described by a standard surface.

**Basic relations and statement of the boundary value problems in terms of holomorphic functions of two complex variables.** We consider a finite elastic cylindrical solid of the height $2h$, which occupies the domain $X$ of Euclidean space delimited by the surface $\partial X$, the cross section of which is described by the canonical curve $f(x_1, x_3) = 0$ referred to the Cartesian coordinate system, the origin of which is in the geometrical center of the solid (Fig. 1). The solid is under the action of a stationary force load applied to the lateral surface $\partial X = \partial X_1 \cup \partial X_3 \cup \partial X_2$.

The solution construction of a linear problem of elasticity in a static formulation reduces to finding a solution of the equations of equilibrium

$$\mu \Delta \vec{u} + (\lambda + \mu) V \times (V \times \vec{u}) = 0. \quad (1)$$

The stress tensor $\vec{\sigma}$ is represented in terms of the vector of displacement $\vec{u}$ by the relationship

$$\vec{\sigma} = \lambda \left[ V \cdot \vec{u} \right] I + \mu \left[ V \otimes \vec{u} + \vec{u} \otimes V \right] = 0, \quad (2)$$

and on the lateral surface $\partial X$ it satisfies the boundary condition

$$\left[ \vec{n} \cdot \vec{\sigma} \right]_{\partial X} = \vec{\sigma}_n = \vec{n} \left[ \lambda \left[ V \cdot \vec{u} \right] I + \mu \left[ V \otimes \vec{u} + \vec{u} \otimes V \right] \right]_{\partial X} = \vec{\sigma}_n, \quad (3)$$

where $I$ is a unit tensor; $\partial X_1$ and $\partial X_3$ are the upper and lower surfaces of the cylindrical solid, for which the normal vector $\vec{n}_3 = \pm \vec{e}_3$; $\partial X_2$ is the lateral surface of the cylindrical solid for which the normal vector $\vec{n}_2 = n_2 \vec{e}_2$, and

$$n_2 = \frac{\partial \vec{r}}{\partial x_3} \sqrt{\sum_{i=1}^{2} \left( \frac{\partial \vec{r}}{\partial x_i} \right)^2} = 0, \quad (i=1,2).$$

where $\vec{u} = (u_1, u_2, u_3) \vec{e}_i$ is the vector of displacement $(i=1,3)$; $(x_i)$ are Cartesian coordinates of the arbitrarily chosen material point $x \in X$; $\vec{e}_i$ are the base unit vectors of the chosen Cartesian system $(0, x_1, x_2, x_3)$; $\vec{V} = \frac{\partial \vec{r}}{\partial x^3} = \vec{e}_3$ is the Hamiltonian $(i=1,3)$; $\lambda \vec{V} \cdot \vec{V} = \frac{\partial^2}{\partial x^2}$ is the Laplacian; $\vec{t} = (x_1, x_2, x_3) \vec{e}_i$ is the radius vector of the arbitrarily chosen point of the solid; $\otimes$ is the operation of dyadic product; $\lambda$, $\mu$ are the Lame elastic constants; $\vec{\sigma}_n(x_1, x_2, x_3)$ is the stress vector; $\vec{\sigma}_n^T(x_1, x_2, x_3)$ is the given vector of superficial applied forces that satisfies the integral conditions of self-equilibrium of external loading on the lateral surface of the solid $\partial X$

$$\int_{\partial X} \vec{\sigma}_n^T d\Sigma = 0; \quad \int_{\partial X} \left( \vec{\sigma}_n^T \times \vec{t} \right) d\Sigma = 0.$$

![Fig. 1. Elastic solid cylindrical body](image-url)
In [19, 20] on the basis of representation of the displacement vector in the Papkovitch-Neuber form

$$\vec{u} = \vec{V}(\vec{q}_0 + \vec{r} \cdot \vec{\varphi}) - 4(1-v)\varphi$$

in terms of the scalar \(\vec{q}_0 = q_0(x_1, x_2, x_3)\) and vectorial \(\vec{\varphi} = \vec{\varphi}(x_1, x_2, x_3)\) harmonic functions, the basic boundary value problem of theory of elasticity (1–3) is reduced to finding the holomorphic functions \(G_0(z_1, z_2), \hat{G}(z_1, z_2)\) satisfying the equation

$$\Delta G_0(z_1, z_2), \Delta \hat{G}(z_1, z_2) = 0,$$  \hspace{1cm} (4)

the boundary conditions

$$T^*_e(z_1, z_2, z_3) = \left[\hat{\vec{T}} \cdot \hat{n}\right]_{\text{ext}} = \left[\hat{\vec{T}} \cdot \hat{\vec{V}} \hat{G}_0(z_1, z_2) + \nabla \cdot (\nabla \times \hat{\vec{V}} \hat{G}_0(z_1, z_2)) \right] - 

\left(1 - 2v\right)\left[\nabla \cdot (\nabla \times \hat{\vec{V}} \hat{G}_0(z_1, z_2)) \right]$$

as well as the corresponding integral conditions of the static equilibrium of an elastic body

$$\oint \left(\hat{\vec{T}} \times \hat{\vec{T}}_{n}\right) d\Sigma = 0,$$

where

$$\left[\hat{\vec{T}} \cdot \hat{\vec{V}} \hat{G}(z_1, z_2) + \nabla \cdot (\nabla \times \hat{\vec{V}} \hat{G}(z_1, z_2)) \right] - 

\left(1 - 2v\right)\left[\nabla \cdot (\nabla \times \hat{\vec{V}} \hat{G}(z_1, z_2)) \right]$$

is a complex vector of displacements;

$$\hat{\vec{T}}(z_1, z_2, z_3) = 2\mu \left[\hat{\vec{V}} \hat{\vec{V}} G_0(z_1, z_2) + 

\left[\hat{\vec{V}} \hat{\vec{V}} G_0(z_1, z_2) \right] \right] - 

\left(1 - 2v\right)\left[\nabla \cdot (\nabla \times \hat{\vec{V}} \hat{G}(z_1, z_2)) \right]$$

is a complex vector of stress tensor;

$$\hat{\vec{T}}_s = \hat{\vec{e}}_a \left[\hat{\vec{e}}_a \cdot \hat{\vec{e}}_a\right] + \hat{\vec{e}}_a \left[\hat{\vec{e}}_a \cdot \hat{\vec{e}}_a\right]$$

is a complex vector of superalifed applied forces;

$$\hat{\vec{T}}(z_1, z_2, z_3) = \frac{(1+i)}{2} \left[\nabla \cdot (\nabla \times \hat{\vec{V}} \hat{G}(z_1, z_2)) \right] - 

\left(1 - 2v\right)\left[\nabla \cdot (\nabla \times \hat{\vec{V}} \hat{G}(z_1, z_2)) \right]$$

is a complex vector of superalifed stress tensor;

$$\Delta = \nabla \cdot \nabla = 2i \frac{\partial^2}{\partial x_i \partial x_i}$$

is the Laplacian.

Note that the representation of the fundamental solution of the basic boundary value problem in terms of the displacement and in the form of Papkovitch-Neuber ensures the satisfaction of the integral condition of the equality of the main vector of external loading to zero.

**General scheme of construction of solutions by means of the method of expansion in terms of the base states.** Basic representations for the formulation of the basic boundary value problems of spatial theory of elasticity are the representations of holomorphic functions \(G_0(z_1, z_2), \hat{G}(z_1, z_2)\) in the form of polynomials of the \(n\)th degree in terms of powers of the complex variables \(z_1\) and \(z_2\)

$$G_0^{(n)}(z_1, z_2) = \sum_{k=0}^{n} M_0^{(k)}(z_1, z_2); \quad \hat{G}^{(n)}(z_1, z_2) = \sum_{k=0}^{n} M^{(k)}(\hat{z}_1, \hat{z}_2),$$

where

$$M_0^{(k)}(z_1, z_2) = \sum_{j=0}^{k} C^{(k-j)}(z_1, z_2); \quad M^{(k)}(z_1, z_2) = \sum_{j=0}^{k} D^{(k-j)}(z_1, z_2),$$

are homogeneous polynomials of the \(k\)th degree of the complex variables \(z_1\) and \(z_2\);

$$C^{(k-j)}(z_1, z_2) = a_{k-j} + ib_{k-j}; \quad D^{(k-j)}(z_1, z_2) = a_{k-j} + id_{k-j},$$

are real numbers; \(m = 1, 3; \quad f, k = 0, n; \quad n \in N.\)

Within the representation (5), the homogeneous polynomials \(M_0^{(k)}, M^{(k)}\) of the \(k\)th degree satisfy Eq. (4), i.e.

$$\frac{\partial^2 M_0^{(k)}}{\partial z_i \partial z_j} = 0; \quad \frac{\partial^2 \hat{M}^{(k)}}{\partial z_i \partial z_j} = 0.$$

In the general case, for construction of a complex stress tensor \(\hat{\vec{T}}^{(k)}\) of the \(n\)th order within the framework of the adopted approach, the basis is a scalar holomorphic function \(G_0(z_1, z_2)\) in the form of a homogeneous polynomial \(M_0^{(n)}(z_1, z_2)\) of the \(n\)th degree and a holomorphic vector function \(\hat{G}(z_1, z_2)\) in the form of a vector homogeneous polynomial \(M^{(n)}(z_1, z_2)\) of the \(n + 1\)th degree, respectively. Thus, we denote

$$G_0^{(n+1)}(z_1, z_2) = C^{(n+1)}(z_1, z_2); \quad G^{(n+1)}(z_1, z_2) = D^{(n+1)}(z_1, z_2); \quad \hat{G}_0^{(n+1)}(z_1, z_2); \quad \hat{G}^{(n+1)}(z_1, z_2).$$

(6)

Then the complex stress tensor of the \(n\)th order is presented in the way

$$\begin{aligned}
\hat{T}^{(k)} &= 2\mu\left[\nabla \cdot (\nabla \times \hat{\vec{V}} \hat{M}^{(n+2)}(\hat{z}_1, \hat{z}_2))\right] - 

\begin{pmatrix}
\nabla \cdot (\nabla \times \hat{\vec{V}} \hat{M}^{(n+1)}(\hat{z}_1, \hat{z}_2)) \\
\nabla \cdot (\nabla \times \hat{\vec{V}} \hat{M}^{(n+1)}(\hat{z}_1, \hat{z}_2))
\end{pmatrix}
\end{aligned}$$

(7)

For each basic stressed state \(\hat{\vec{T}}^{(k)}\) of the \(k\)th order, the expression of the stress vector \(T^{(k)}\) will be initial for the notation of the corresponding structure of boundary conditions on the lateral surface of the body \(\partial X\) with the normal \(\hat{\vec{n}} = \hat{\vec{e}}_a(\hat{\vec{e}}_a \cdot \hat{\vec{e}}_a), \hat{\vec{e}}_a(\hat{\vec{e}}_a \cdot \hat{\vec{e}}_a)\)

$$\begin{aligned}
\hat{T}^{(k)}(\hat{\vec{\vec{n}}}, \hat{\vec{T}}^{(k)}) = 2\mu\left[\nabla \cdot (\nabla \times \hat{\vec{V}} \hat{M}^{(n+2)}(\hat{z}_1, \hat{z}_2))\right] - 

\begin{pmatrix}
\nabla \cdot (\nabla \times \hat{\vec{V}} \hat{M}^{(n+1)}(\hat{z}_1, \hat{z}_2)) \\
\nabla \cdot (\nabla \times \hat{\vec{V}} \hat{M}^{(n+1)}(\hat{z}_1, \hat{z}_2))
\end{pmatrix}
\end{aligned}$$

Moreover, on the lateral surface of the body \(\partial X\), the vector of the complex external load \(\hat{T}^{(k+1)}\) is equal to the stress vector \(\hat{T}^{(k+1)}\), i.e. \(\hat{T}^{(k+1)} = \hat{T}^{(k)}\).

This method of finding solutions of basic boundary value problems of the theory of elasticity will be applied to a cylindrical elastic body in the case when the complex stress tensor does not depend on the spatial coordinate \(x_3\).

The specified condition, which is given by the relation

$$\frac{\partial \hat{T}(z_1, z_2, z_3)}{\partial x_3} = \left(\frac{\partial}{\partial z_2} + \frac{i}{\partial z_1} + \frac{\partial}{\partial z_2}ight)\hat{T}(z_1, z_2, z_3) = 0,$$  \hspace{1cm} (8)
imposes relations between the coefficients of scalar $G_0(z_1, z_2)$ and vectorial $\mathcal{G}(z_1, z_2)$ holomorphic functions.

Let us apply the condition to the basic solutions of the $k$th order of the complex stress tensor $\hat{T}^{(k)}$, whose structure is determined by the holomorphic functions $G_k(z_1, z_2), \mathcal{G}_k(z_1, z_2)$ in the form of homogeneous polynomials (6).

As an example, consider the solution of the boundary value problem of theory of elasticity, which is characterized by the complex second-order tensor.

Taking into account the relation (7) and the condition (8), we obtain the recurrence formula for the basic solution $\hat{T}^{(k)}$ of the $k$th order

$$\hat{T}^{(k)} = 2\mu_2 \delta^{(k)}k \left( \hat{K}(k) z_1 + \hat{K}(k) (z_2 - iz_3) \right),$$

where $\hat{K}(k), \hat{K}(3)$ are the constant tensor coefficients, which are expressed in terms of coefficients of the holomorphic functions $G_k(z_1, z_2), \mathcal{G}(k)(z_1, z_2)$.

Let us represent a structure of the stress vectors on the lateral surface of the body $\partial X$ with the normal $\vec{n} = n_1(x_1, x_2, x_3)\vec{e}_1$.

For each basic solution $\hat{T}^{(k)}$ of the $k$th order, the stress vector is represented as follows

$$\hat{T}^{(k)}(\vec{n}) = \left(\begin{array}{c} \hat{T}^{(k)}_{x_1} \\ \hat{T}^{(k)}_{x_2} \\ \hat{T}^{(k)}_{x_3} \end{array}\right) = 2\mu \delta^{(k)}k \left[ \left( \hat{K}(k) z_1 + \hat{K}(k) (z_2 - iz_3) \right) \right] \left(\begin{array}{c} 1 \\ i \\ -1 \end{array}\right).$$

For the given cylindrical solid, the stress vectors on the surfaces $\partial X$ and $\partial X_3$ have the following forms:

- on the surface $\partial X_2$, we have $\vec{n}_2 = n_2\vec{e}_2$, $i = 1, 2$

$$\hat{T}^{(k)}(\vec{n}) = \left(\begin{array}{c} \hat{T}^{(k)}_{x_1} \\ \hat{T}^{(k)}_{x_2} \\ \hat{T}^{(k)}_{x_3} \end{array}\right) = 2\mu \delta^{(k)}k \left[ \left( \hat{K}(k) z_1 + \hat{K}(k) (z_2 - iz_3) \right) \right] \left(\begin{array}{c} 1 \\ i \\ -1 \end{array}\right).$$

- on the surface $\partial X_3$, we have $\vec{n}_3 = \pm \vec{e}_3$ we have

$$\hat{T}^{(k)}(\vec{n}) = \left(\begin{array}{c} \hat{T}^{(k)}_{x_1} \\ \hat{T}^{(k)}_{x_2} \\ \hat{T}^{(k)}_{x_3} \end{array}\right) = 2\mu \delta^{(k)}k \left[ \left( \hat{K}(k) z_1 + \hat{K}(k) (z_2 - iz_3) \right) \right] \left(\begin{array}{c} 1 \\ i \\ -1 \end{array}\right).$$

In this connection, the boundary conditions for the base stressed state $\hat{T}^{(2)}$ of the $k$th order on the lateral surfaces of the body $\partial X$, $\partial X_3$ are the conditions of balancing of the stress vectors $\hat{T}^{(k)}$, $\hat{T}^{(k)}$ by the given external load vectors $\hat{T}^{(k)}_{x_1}(x_1), \hat{T}^{(k)}_{x_2}(x_1)$.

Let us analyze the basic solutions of complex-conjugate problems. As an example, consider a second-order basic solution $\hat{T}^{(2)}$

$$\hat{T}^{(2)} = \Re \hat{T}^{(2)} + i \Im \hat{T}^{(2)} = \left( \Re \hat{T}^{(2)} + i \Im \hat{T}^{(2)} \right) \vec{e}_2 \otimes \vec{e}_1.$$

Accordingly, the components of the stress tensor for the real part of the solution of the problem in the basis of the Cartesian coordinate system $\{\vec{e}_1\}$ are given in terms of the real and imaginary parts of the coefficients of the holomorphic functions $a_{i1}(x_1, x_2), b_{i1}(x_1, x_2), c_{i1}(x_1, x_2), \cdots, a_{i1}^{(k-n)}, b_{i1}^{(k-n)}, c_{i1}^{(k-n)}, m = \sqrt{3}, j, k = 0, \pm 4$. For example, the component of the stress tensor $T^{(2)}$ is written as follows:

- for the real part of the solution

$$\Re T^{(2)}_{11} = 6\mu \left[ 4a_{00}^2 + 2c_{00}^3 - d_{00}^3 + 4c_{00}^2 x_1^2 + \left[ -4a_{00} \left( 1 - 2c_{00} + 2c_{00}^3 - 2d_{00}^3 + 6c_{00}^2 d_{00}^3 \right) x_1^2 + \right. \right.$$

Then the stress vector for the imaginary part $\Im T^{(2)}$ of the solution takes the form

Applying the method of holomorphic functions for constructing a solution for an elastic cylindrical drill. As an example, we consider the boundary value problem of theory of elasticity, which describes the distribution of stresses and corresponding external loads on the lateral surface of a cylindrical body (drill) of an elliptical cross-section, geometrically delimited by the surfaces

$$\partial X_2: \quad f(x_1, x_2) = \frac{x_2^2}{a^2} + \frac{x_1^2}{b^2} = 1 = 0;$$

$$\partial X_3: \quad x_3 = \pm \epsilon h.$$
In Fig. 2, there are schematically depicted vectors of external load that correspond to the real part of the basic solution.

### Conclusions

The results obtained in this paper have shown that using the method of constructing the basic solutions of spatial problems of theory of elasticity on the basis of representation of holomorphic functions in the terms of polynomials of the n-th degree with respect to complex variables \( z_1 \) and \( z_2 \) it is possible to form a structure of a set of exact analytic solutions for an elastic deformable body. Such an approach allows us to obtain a superposition of exact analytic solutions for an elastic deformable body. In this paper, an example of using the developed methods for constructing solutions of boundary value problems of spatial theory of elasticity has been considered for finding an exact solution of a two-dimensional boundary value problem.

This boundary value problem simulates the distribution of stresses and of corresponding external loads on the lateral surface of a cylindrical solid (drill) of canonical cross-section. As follows from the results of the study on the mathematical model considered in this paper, the suggested approach allows us to construct and analyze the structure of the external load, which, in turn, can be used to synthesize the parameters of the boring equipment which provide efficient modes of its operation.

Робота сформульована комплексно спряжені краєві задачі просторової теорії пружності в голоморфних функціях двох комплексних змінних. Розглянута постановка задачі у випадку, коли тензор напруження не залежить від однієї із просторових координат для тіл, обмежених канонічними кривими. Для заданого скінченного пружного циліндричного тіла (бура) канонічного поперечного перетину побудована структура базових комплексних розв’язків порядку \( n \) і відповідних векторів зовнішніх навантажень.

Наукова новизна. У роботі вперше запропонована схема та методика побудови розв’язків базових краївих задач просторової теорії пружності і голографмічно спрямовані відповідні краєві умови, побудовані дійсна та уявна складови розв’язків базових краївих задач для циліндричного бура та проведене аналіз цих розв’язків.

Практична значимість. Розглянуто приклад використання розроблених методів побудови розв’язків краївих задач просторової теорії пружності для знаходження точного аналітичного розв’язку двовимірної краєвої задачі, що описує розподіл напружень і відповідних зовнішніх навантажень на бічній поверхні циліндричного бура канонічного поперечного перетину. Такі математичні моделі та аналіз структури зовнішнього навантаження можуть бути ефективно використані для опису безпечних режимів роботи гірничого буринного обладнання.

Ключові слова: теорія пружності, тензор напружень, вектор переміщення, вектор зовнішніх навантажень, голоморфна функція.

Методи двумерної теории упругости для описания напряжённого состояния и режимов работы упругого бура

В. В. Пабиривский, И. В. Кузьо, Н. В. Пабиривская, П. Я. Пукач

Государственное высшее учебное заведение Национальный университет «Львовская политехника», г. Львов, Украина e-mail: pabvic67@gmail.com

Цель. Нахождение напряженного состояния и описание режимов работы важного элемента горного промышленного оборудования – упругого вала на основе методики построения базовых решений краевых задач статической теории упругости с использованием голоморфных функций двух комплексных переменных.

Методика. Методика построения базовых решений пространственных задач теории упругости основывается на основе представления фундаментального решения уравнений Ляме в форме Папковича–Нейбера через скалярную и векторную гармонические функции и формулирование совместимости комплексно сопряженных краевых задач в голоморфных функциях комплексных переменных. На основе представления вышеупомянутых голоморфных функций в виде многочленов порядка \( n \) степеней комплексных переменных сформулированы соответствующие граничные условия для базовых решений и конкретизированы дополнительно интегральные условия равенства нулю главного момента вектора напряжений на боковой поверхности тела.

Результаты. В работе сформулированы комплексно сопряженные краевые задачи пространственной теории упругости в голоморфных функциях двух комплексных переменных. Рассмотрена постановка задачи в случае, когда тензор напряжений не зависит от одной из пространственных координат для тел, ограниченных каноническими кривыми. Для заданного конечного упругого цилиндрического тела (бура) канонического поперечного пересечения построена структура базовых комплексных решений краевой задачи для циліндричного бура и проведен анализ этих решений.

Практическая значимость. Рассмотрен пример использования разработанных методов построения решений краевых задач пространственной теории упругости и сформулированы соответствующие граничные условия, построены действительные и мнимые составляющие решений базовых краевых задач для цилиндрического бура и проведен анализ этих решений.

Ключевые слова: теория упругости, тензор напряжений, вектор перемещений, вектор внешних нагрузок, голоморфная функция.
