Abstract

We investigate the dimension two condensate $\langle \bar{\phi}^{ab} \phi^{ab} - \bar{\omega}^{ab} \omega^{ab} \rangle$ within the Gribov-Zwanziger approach to Euclidean Yang-Mills theories in the Coulomb gauge, in both 3 and 4 dimensions. An explicit calculation shows that, at the first order, the condensate $\langle \bar{\phi}^{ab} \phi^{ab} - \bar{\omega}^{ab} \omega^{ab} \rangle$ is plagued by a non-integrable IR divergence in 3D, while in 4D it exhibits a logarithmic UV divergence, being proportional to the Gribov parameter $\gamma^2$. These results indicate that in 3D the transverse spatial Coulomb gluon two-point correlation function exhibits a scaling behaviour, in agreement with Gribov’s expression. In 4D, however, they suggest that, next to the scaling behaviour, a decoupling solution might emerge too.

1 Introduction

The Coulomb gauge, $\partial_i A^a_i = 0$, $i = 1, ..., D - 1$, is largely employed in analytic [1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 15, 16, 17, 18, 19, 20, 21, 22] as well as in lattice numerical investigations [23, 24, 25, 26, 27] of non-perturbative aspects of Euclidean Yang-Mills theories. An impressive number of results are nowadays available in this gauge, providing a consistent scenario for confinement.

In this letter we focus on aspects of the Gribov-Zwanziger formulation of the Coulomb gauge [28, 3, 4, 6, 8], which implements the restriction of the domain of integration in the functional Euclidean integral to the Gribov Region $\Omega$, defined as the set of all field configurations fulfilling the Coulomb condition and for which the Faddeev-Popov operator, $\mathcal{M}^{ab} = -\delta^{ab} \partial_i \partial_i - g f^{acb} A^c_i \partial_i$, is strictly positive, namely

$$\Omega = \{ A^a_i , \partial_i A^a_i = 0 , \mathcal{M}^{ab} > 0 \} .$$

The restriction to the region $\Omega$ accounts for the existence of the Gribov copies, which affect the Coulomb gauge. The so called Gribov-Zwanziger action [28, 3, 4, 6, 8] is the final result of the restriction to the region $\Omega$. Besides the Coulomb gauge, the restriction to the Gribov region has been effectively implemented in the Landau [28, 29, 30] and maximal Abelian gauges [31, 32], where the corresponding Gribov-Zwanziger actions have been worked out. A feature of the Gribov-Zwanziger set up in the Landau and maximal Abelian gauges is that the two-point gluon correlation function is strongly suppressed in the infrared region in momentum space $k$, attaining a vanishing value when $k = 0$. This kind of behaviour is

---

*msguimaraes@uerj.br
†bruno.mintz.uerj@gmail.com
‡silvio.sorella@gmail.com
usually referred to as the scaling solution, also observed in the study of the Dyson-Schwinger equations in these gauges, see \[33\] [44]. Such a behaviour is also found for the spatial gluon correlation function in the Coulomb gauge.

Nevertheless, next to the scaling solution, another type of solution, called decoupling solution, was found in both Landau [35, 36, 37, 38, 39, 40, 41] and maximal Abelian gauges [42, 43, 44], in both 3 and 4 dimensions. Similarly to the scaling solution, the decoupling solution is also strongly suppressed in the infrared region, displaying a violation of positivity. However, it does not attain a vanishing value at \( k = 0 \).

Within the Gribov-Zwanziger approach, the decoupling solution arises as the consequence of the existence of dimension two condensates \[37, 39, 40, 42, 43, 44\]. The resulting action accounting for the inclusion of these condensates is known as the Refined-Gribov-Zwanziger action [37, 39, 40, 42, 43, 44].

In the present work, we investigate the condensate \( \langle \phi^a_i \phi^a_i - \bar{\omega}_i^{ab} \omega_i^{ab} \rangle \) in Coulomb gauge, in both 3 and 4 dimensions. In 3D we find, by an explicit first order calculation, that the integral defining \( \langle \phi^a_i \phi^a_i - \bar{\omega}_i^{ab} \omega_i^{ab} \rangle \) exhibits a non-integrable IR divergence, showing that the condensate cannot be safely introduced in 3D.

As a consequence, in 3D, the transverse equal-time gluon propagator exhibits the scaling type behaviour given by Gribov’s expression.

Moreover, in 4D, we find that the condensate is safe in the IR, being plagued by a mild UV logarithmic divergence, precisely as the gap equation defining the Gribov parameter. This suggests that, apart from a UV proper renormalization, a non-vanishing dimension two condensate \( \langle \phi^a_i \phi^a_i - \bar{\omega}_i^{ab} \omega_i^{ab} \rangle \) might show up also in the Coulomb gauge. As a consequence, the spatial transverse two-point gluon correlation function exhibits a decoupling solution, next to the well known scaling one. To some extent, this suggests a kind of common feature of the Landau, Coulomb and maximal Abelian gauge in 4D Euclidean space-time.

The present letter is organised as follows. In Sect.2 we give a short overview of the Gribov-Zwanziger action in the Coulomb gauge. Sect.3 is devoted to the evaluation of the condensate \( \langle \phi^a_i \phi^a_i - \bar{\omega}_i^{ab} \omega_i^{ab} \rangle \) at the first order, in both 3D and 4D.

## 2 The Gribov-Zwanziger action in the Coulomb gauge

The Gribov-Zwanziger action implementing the restriction to the Gribov region \( \Omega \), eq.(1), in the Coulomb gauge, \( \partial_i A^a_i = 0 \), \( i = 1, \ldots, (D - 1) \), reads [28, 3, 4, 6, 8]

\[
S_{GZ} = \int d^Dx \left( \frac{1}{4} F_{\mu \nu}^a F_{\mu \nu}^a + b^a \partial_i A^a_i + c^a \partial_i D_i^{ab} c^b \right) \\
+ \int d^Dx \left( -\bar{\phi}^a_i \partial_i \phi^a_i + \bar{\omega}_i^{ab} \partial_i D_i^{ab} \omega_i^{ab} - g f^{acm} (\partial_i \omega_i^{ab}) (D_i^{cp} c^p) \phi_i^{mc} \right) \\
+ \int d^Dx \left( \gamma^2 g f^{abc} A_i^a (\phi_i^{bc} - \bar{\phi}_i^{bc}) - (D - 1)(N^2 - 1) \gamma^4 \right). \tag{2}
\]

The field \( b^a \) is the Lagrange multiplier enforcing the Coulomb condition, \( \partial_i A^a_i = 0 \), while the fields \( (\bar{c}^a, c^a) \) are the Faddeev-Popov ghosts. The fields \( (\bar{\phi}^a_i, \phi^a_i) \), \( \partial_i \), \( D_i^{ab} \), are a set of commuting fields while \( (\bar{\omega}_i^{ab}, \omega_i^{ab}) \) are anti-commuting. These fields are introduced in order to implement the restriction to the region \( \Omega \) through a local action, eq.(2). Finally, the parameter \( \gamma^2 \) appearing in expression (2) is the Gribov parameter. It has the dimension of mass squared and has a dynamical origin, being determined
in a self consistent way through the gap equation
\[ \frac{\partial E_v}{\partial \gamma^2} = 0, \]
where \( E_v \) is the vacuum energy, namely
\[ e^{-V}E_v = \int [D\Phi] e^{-S_{GZ}}. \]

To the first order
\[ E_v = -(D-1)(N^2-1)\gamma^4 + \frac{(D-2)}{2}(N^2-1) \int \frac{d^Dk}{(2\pi)^D} \log \left( k_D^2 + k^2 + \frac{2Ng^2\gamma^4}{k^2} \right) + \text{terms independent from } \gamma^2, \]
so that the gap equation, eq. (3), takes the form
\[ \int \frac{d^Dk}{(2\pi)^D} k_D^2 k^2 + k^4 + 2Ng^2\gamma^4 = \frac{(D-1)}{(D-2)} \frac{1}{2Ng^2}. \]

From the Gribov-Zwanziger action, it follows that the tree level two-point gluon spatial correlation function is given by
\[ (A_i^a(k)A_j^b(-k)) = \frac{\delta^{ab}}{k_D^2 + k^2 + 2Ng^2\gamma^4} \left( \delta_{ij} - \frac{k_ik_j}{k^2} \right), \]
leading to an equal-time transverse form factor [27]
\[ D_{GZ}^{tr}(k) = \frac{|k|}{\sqrt{k^2 + 2Ng^2\gamma^4}}, \]
which exhibits the scaling behaviour, \( D_{GZ}^{tr}(0) = 0 \). Before going any further, it is worth reminding briefly how expression (7) is derived. A simple calculation shows in fact that the quadratic part of the Gribov-Zwanziger action in the gluon sector takes the following form
\[ S_{GZ}^{\text{quadr}} = \int d^Dx \left( \frac{1}{2} A_D^{\mu}(\vec{\nabla}^2) A_D^{\mu} + \frac{1}{2} A_i^a \left( -\partial_D^2 - \vec{\partial}^2 + \frac{2Ng^2\gamma^4}{-\partial^2} \right) A_i^a + b^a \partial_i A_i^a \right), \]
from which one immediately derives the tree level expression for the transverse spatial gluon propagator given in eq. (7). Moreover, one has to observe that, unlike expression (7), the tree level temporal correlator \( (A_D^a(k)A_D^b(-k)) \) does not display an energy resolution, due to the well known existence of residual temporal gauge transformations which affect the Coulomb condition. The resolution of the energy behaviour of this correlation function is a quite delicate point which requires a detailed mastering of the renormalization procedure of the Coulomb gauge. Here, we remind the reader to the large literature existing on this subject, both in the continuum as well as in the lattice formulation [1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 15, 16, 17, 18, 19, 20, 21, 22, 23, 24, 25, 26, 27].

3 The dimension two condensate \( \langle \vec{\phi}_i^a \phi_i^{ab} - \vec{\omega}_i^{ab} \omega_i^{ab} \rangle \)

In order to evaluate the condensate \( \langle \vec{\phi}_i^a \phi_i^{ab} - \vec{\omega}_i^{ab} \omega_i^{ab} \rangle \), we couple the operator \( \langle \vec{\phi}_i^a(x)\phi_i^{ab}(x) - \vec{\omega}_i^{ab}(x)\omega_i^{ab}(x) \rangle \) to a constant source \( J \), i.e.
\[ S_{GZ} \rightarrow S_{GZ} + \int d^Dx J \left( \vec{\phi}_i^a(x)\phi_i^{ab}(x) - \vec{\omega}_i^{ab}(x)\omega_i^{ab}(x) \right), \]
and we evaluate
\[ e^{-VE_v(J)} = \int [\mathcal{D}\Phi] e^{-\left( S_{GZ} + \int d^Dx J(\tilde{\phi}_i^{ab}(x)\phi_i^{ab}(x) - \tilde{\omega}_i^{ab}(x)\omega_i^{ab}(x)) \right)} . \] (11)
The condensate is thus obtained by differentiating \( E_v(J) \) with respect to \( J \) and setting \( J = 0 \) at the end, namely
\[ \frac{\partial E_v(J)}{\partial J} \bigg|_{J=0} = \frac{\int [\mathcal{D}\Phi]}{\int [\mathcal{D}\Phi]} \left( \tilde{\phi}_i^{ab}(x)\phi_i^{ab}(x) - \tilde{\omega}_i^{ab}(x)\omega_i^{ab}(x) \right) e^{-S_{GZ}} = \langle \tilde{\phi}_i^{ab} - \tilde{\omega}_i^{ab} \rangle . \] (12)
At the first order, we get
\[ E_v(J) = \frac{D-2}{2}(N^2 - 1) \int \frac{d^Dk}{(2\pi)^D} \log \left( k_D^2 + \vec{k}^2 + \frac{2Ng^2\gamma^4}{k^2 + J} \right) + \text{terms independent from } J . \] (13)
Taking the derivative with respect to \( J \) and setting \( J = 0 \), it turns out that
\[ \langle \tilde{\phi}_i^{ab} - \tilde{\omega}_i^{ab} \rangle = -Ng^2\gamma^4(N^2 - 1)(D-2) \int \frac{d^Dk}{(2\pi)^D} \frac{1}{k_D^2 + \vec{k}^2 + 2Ng^2\gamma^4} \frac{1}{k^2} . \] (14)

3.1 The 3D case

Let us start by considering first expression (13) in 3D. Here, we have
\[ \langle \tilde{\phi}_i^{ab} - \tilde{\omega}_i^{ab} \rangle = -Ng^2\gamma^4(N^2 - 1) \int \frac{dk_3}{(2\pi)^3} \frac{d^2\vec{k}}{k^2 + \vec{k}^2 + 2Ng^2\gamma^4} \frac{1}{k^2} , \] (15)
while for the gap equation
\[ \int \frac{dk_3}{(2\pi)^3} \frac{d^2\vec{k}}{k^2 + \vec{k}^2 + 2Ng^2\gamma^4} = \frac{1}{Ng^2} . \] (16)
We see that, while the integral defining the gap equation, eq. (16), is convergent in both IR and UV regions, the expression for the condensate, eq. (15), exhibits a non-integrable singularity in the IR, due to the presence of the term \( \frac{1}{k^2} \) which is non-integrable in two-dimensional space. This indicates that the condensate \( \langle \tilde{\phi}_i^{ab} - \tilde{\omega}_i^{ab} \rangle \) cannot be introduced in 3D, due to the existence of infrared divergences. A similar phenomenon occurs in the Landau gauge in 2D, where the analogous condensate cannot be introduced due to infrared divergences [45].

3.2 The 4D case

Let us turn now to the 4D case, where for the condensate and for the gap equation we get
\[ \langle \tilde{\phi}_i^{ab} - \tilde{\omega}_i^{ab} \rangle = -2Ng^2\gamma^4(N^2 - 1) \int \frac{dk_4}{(2\pi)^4} \frac{d^3\vec{k}}{k^2 + \vec{k}^2 + 2Ng^2\gamma^4} \frac{1}{k^2} , \] (17)
and
\[ \int \frac{dk_4}{(2\pi)^4} \frac{d^3\vec{k}}{k^2 + \vec{k}^2 + 2Ng^2\gamma^4} = \frac{3}{2} \frac{1}{2Ng^2} . \] (18)
In this case, both expressions are safe in the IR, while they suffer from UV divergences which should be handled by a suitable renormalization procedure in the Coulomb gauge. In fact, taking a closer look at the expression (17), we may write
\[ \langle \tilde{\phi}_i^{ab} - \tilde{\omega}_i^{ab} \rangle = -Ng^2\gamma^4(N^2 - 1) \frac{1}{\pi^3} \int_0^\infty dp \int_0^\infty dr \frac{1}{\rho^2 + r^2 + 2Ng^2\gamma^4} . \] (19)
where use has been made of three dimensional polar coordinates. Making the change of variables
\[ \rho \rightarrow (2N\gamma^2)^{1/4} \rho, \quad r \rightarrow (2N\gamma^2)^{1/4} r, \]
we get
\[ \langle \bar{\phi}_i^{ab} \phi_i^{ab} - \bar{\omega}_i^{ab} \omega_i^{ab} \rangle = -(N^2 - 1) \sqrt{2g^2} N \gamma^2 \frac{1}{2\pi^3} \int_0^\infty d\rho \int_0^\infty dr \frac{1}{\rho^2 r^2 + r^4 + 1}. \]
To evaluate the integral
\[ I = \int_0^\infty d\rho \int_0^\infty dr \frac{1}{\rho^2 r^2 + r^4 + 1}, \]
we adopt two-dimensional polar coordinates, \((\rho = R\cos \theta, r = R\sin \theta)\), obtaining
\[ I = \int_{\Lambda_0}^{\sqrt{2}} dR \int_0^{\pi/2} d\theta \frac{1}{R^4 \sin^2 \theta + 1}, \]
where \(\Lambda\) is a cutoff. From
\[ \int_0^\theta d\theta \frac{1}{R^4 \sin^2 \theta + 1} = \frac{\arctan(\sqrt{R^4 + 1} \tan \phi)}{\sqrt{R^4 + 1}}, \]
we finally get
\[ I = \frac{\pi}{2} \int_{\Lambda_0}^{\sqrt{2}} dR \frac{R}{\sqrt{R^4 + 1}} = \frac{\pi}{4} \text{arcsinh}(2\Lambda^2), \]
which diverges logarithmically as \(\Lambda \to \infty\).

We see therefore that, apart from a UV renormalization, a non-vanishing two-dimensional condensate
\[ \langle \bar{\phi}_i^{ab} \phi_i^{ab} - \bar{\omega}_i^{ab} \omega_i^{ab} \rangle \]
might emerge in 4D. The effect of this condensate on the dynamics of the theory can be taken into account by introducing the Refined Gribov-Zwanziger action in the Coulomb gauge
\[ S_{RGZ} = S_{GZ} + \int d^4 x \mu^2 \left( \bar{\phi}_i^{ab}(x)\phi_i^{ab}(x) - \bar{\omega}_i^{ab}(x)\omega_i^{ab}(x) \right), \]
where the parameter \(\mu^2\) can be obtained order by order by evaluating the effective potential for the operator \(\bar{\phi}_i^{ab}(x)\phi_i^{ab}(x) - \bar{\omega}_i^{ab}(x)\omega_i^{ab}(x)\), as done in [46] in the case of the Landau gauge. Evaluating now the spatial two-point gluon correlation function with the refined action (26), one gets the decoupling solution
\[ \langle A_\xi^a(k)A_{\xi'}^b(-k) \rangle_{RGZ} = \frac{\delta^{ab}}{k_\xi^2 + k_{\xi'}^2 + 2N\gamma^2 + \mu^2}, \]
leading to an equal time transverse form factor of the decoupling type, namely
\[ D^\Lambda_{\text{tr}}(k) = \frac{\sqrt{k^2 + \mu^2}}{\sqrt{k^2 + \mu^2} + 2Ng^2\gamma^4}. \]
Even if being well beyond the aim of the present letter, one might expect that the existence of a decoupling type behavior for the transverse gluon propagator should entail modifications on the infrared behavior of the ghost, perhaps resulting in a milder behavior of the ghost form factor in the deep infrared region, similarly to what happens in the Landau gauge. It is worth in fact to point out that, within the Schwinger-Dyson approach, a decoupling type solution for the transverse gluon and its consequences on the ghost form factor as well as on the Coulomb potential have been already analysed by the authors of [47]. We hope to report soon on this important topic, which deserves a more complete and detailed analysis.
