The vascular leakage in diabetic retinopathy leads to macular edema and vision loss. Although astrocyte play an important role in regulating blood-brain barrier integrity in the brain, the precise role of astrocyte in blood-retinal barrier was yet to be elucidated. This study aimed to investigate the role of angiopoietin 2 (Ang2) in astrocyte loss and vascular leakage in the early streptozotocin-induced diabetic retinopathy. We demonstrated that vascular leakage occurred with astrocyte loss in early diabetic mice retina as Ang2 increased. The astrocyte loss and vascular leakage were inhibited by intravitreal injection of Ang2-neutralizing antibody. \( \text{In vitro} \), Ang2 aggravated high glucose-induced astrocyte apoptosis via GSK-3\( \beta \) activation. Ang2 directly bound to \( \alpha v \beta 5 \) integrin, which was abundant in astrocyte, and the blockade of \( \alpha v \beta 5 \) integrin, \( \text{in vitro} \), effectively attenuated Ang2-induced astrocyte apoptosis. \( \text{In vivo} \), intravitreal injection of anti-\( \alpha v \beta 5 \)-integrin antibody inhibited astrocyte loss in early diabetic retinopathy. Taken together, Ang2 induced astrocyte apoptosis under high glucose via \( \alpha v \beta 5 \)-integrin/GSK-3\( \beta \)/\( \beta \)-catenin pathway. Therefore, we suggest that Ang2/integrin signaling could be a potential therapeutic target to prevent the vascular leakage by astrocyte loss in early diabetic retinopathy.

Cell Death and Disease (2016) 7, e2101; doi:10.1038/cddis.2015.347; published online 18 February 2016

Diabetic retinopathy (DR) is the most common microvascular complication and the leading cause of vision impairment in the diabetic patients and working-aged people.\(^1\) Although neovascularization cause severe vision loss only in the later proliferative phase of DR, macular edema caused by vascular leakage can occur at any stage of DR and impair visual acuity.\(^2\)

In brain, the role of astrocyte as a component of neurovascular unit in the regulation of the blood-brain barrier (BBB) is well established. The perivascular endfeet of astrocyte contribute to the BBB features.\(^3\) In addition, astroglial-endothelial signaling regulates the BBB under pathological conditions.\(^3,4\) Recently, retinal dysfunction in diabetes is explained by a subsequent change of the retinal neurovascular unit in terms of retinal pathophysiology.\(^1,5\) However, the precise role of astrocyte in the regulation of the blood-retinal barrier (BRB) in diabetic retina has not been elucidated.

In the retina, both astrocyte and Müller cells are involved in vascular ensheathment. However, astrocyte and Müller cells are affected by diabetes in different ways.\(^6,7\) Although astrocyte is limited to the ganglion cell layer, astrocyte plays an important role in vessel integrity both via direct contact and through humoral factors.\(^8,9\) In addition, astrocyte is closely related to the formation of tight junction in developing retina.\(^10–12\) Moreover, retinal astrocyte may decrease in number at sites where vessel is damaged with increased permeability of the BRB in pathologic conditions.\(^13,14–15\) Thus, in this study, we focused on the role of astrocyte regarding to the vascular leakage in diabetic retina.

Recently, we have demonstrated that angiopoietin 2 (Ang2) induces pericyte apoptosis via integrin signaling in DR.\(^16\) Hyperglycemia-induced Ang2 has a central role in pericyte apoptosis by Ang2/\( \alpha v \beta 3 / 1 \)-integrin/p53 signaling pathway in streptozotocin (STZ)-induced diabetic mice. Local vascular leakage occurs early in the experimental diabetic mice even before the pericyte loss.\(^5\) In addition, Ang2 is upregulated by hyperglycemia in endothelial cells and diabetic retina.\(^17–19\) Moreover, Ang2 binds to integrin and regulates angiogenesis.\(^20\) In view of neurovascular unit, we postulated that Ang2 could affect astrocyte via integrin signaling before the pericyte loss in diabetic retina.

Abbreviations: Ang2, angiopoietin 2; BBB, blood-brain barrier; BRB, blood-retinal barrier; DR, diabetic retinopathy; FACS, fluorescence-activated cell sorting; FITC, fluorescein isothiocyanate; GFAP, glial fibrillary acidic protein; GRGDS, H-Gly-Arg-Gly-Asp-Ser-OH; HRMECs, human retinal microvascular endothelial cells; MTT, 3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide; PARP, poly(ADP-ribose) polymerase; PI, propidium iodide; STZ, streptozotocin; VEGF, vascular endothelial growth factor.
Here, we provide evidence for the role of Ang2-induced astrocyte loss in vascular leakage in early diabetic retina. We demonstrate that Ang2 shows synergistic effects with high glucose on astrocyte apoptosis via GSK-3β/β-catenin pathway. Furthermore, we demonstrate both in vitro and in vivo that blocking αvβ5 integrin effectively attenuate Ang2-induced astrocyte apoptosis. Taken together, Ang2-induced astrocyte apoptosis via αvβ5-integrin signaling contributes to the vascular leakage in diabetic retina.

**Results**

**Retinal astrocyte loss occurs with retinal vascular leakage in early diabetic mice.** To determine whether retinal astrocyte coverage to retinal vessel is attenuated in diabetic mice retina, we performed immunohistochemistry in retinal flat mounts of diabetic mice. Retinal vascular coverage by glial fibrillary acidic protein (GFAP)-labeled astrocyte was evaluated in 3 weeks of STZ-induced diabetes and age-matched non-diabetic control mice. Intriguingly, focal loss of astrocyte coverage to retinal vessel was observed in diabetic retina (Figure 1a). The relative astrocyte coverage to retinal vessel (42.0±6.4%) was significantly decreased in the diabetic retina compared to that of the control retina (100.0±5.4%, P<0.001; Figure 1b). The retinal vascular leakage was also evaluated with fluorescein isothiocyanate (FITC)-dextran. The retinal vascular leakage (196.5±7.1%) was significantly increased in the diabetic retina compared to that of the control retina (100.0±16.0%, P<0.001; Figure 1c). In early diabetic mice, retinal astrocyte loss occurred with increase in retinal vascular leakage.

**Inhibition of Ang2 reduces astrocyte loss and vascular leakage in early diabetic retina.** To determine which growth factor is linked to increased vascular leakage and astrocyte loss in early diabetic retina, we performed ELISA for retinal vascular endothelial growth factor (VEGF) and Ang1/2. Retinal Ang2 level was increased at 1 and 3 weeks after diabetic induction (from 88.9±1.3 pg/mg to 98.11±2.2 and 102.7±4.6 pg/mg, respectively, P=0.018 by one-way ANOVA; Supplementary Figure S1a). With post hoc test, retinal Ang2 at 3 weeks was significantly increased compared to control (P=0.017; Supplementary Figure S1a). However, retinal VEGF and Ang1 levels were not significantly changed up to 3 weeks after diabetic induction (Supplementary Figures S1b and c). In qPCR analysis of diabetic retina (up to 7 weeks after diabetic induction), Ang2 and Ang1 mRNAs were significantly elevated after 3 weeks (Figures 2a and b). However, Vegfa mRNA was significantly increased after 5 weeks. (Figure 2c). The physical and metabolic parameters of the mice used in ELISA and qPCR were shown in Figure 2g. To explore the possibility that the increased vascular leakage was due to the astrocyte loss by Ang2, we injected Ang2-blocking antibody in diabetic mice at 2 weeks after STZ injection. The retina of anti-Ang2-blocking antibody-injected mice showed increased astrocyte coverage (349.3±49.8%) compared to the loss of astrocyte coverage in PBS-injected diabetic mice (100.0±15.2%, P<0.05; Figures 2d and e). In addition, anti-Ang2-blocking antibody attenuated vascular leakage (72.4±6.3%) compared to the vascular leakage in PBS-injected diabetic retina (100.0±5.3%, P<0.05; Figure 2f). These findings suggested that astrocyte loss by Ang2 was associated with retinal vascular leakage and it could contribute to retinal vascular leakage in the STZ-diabetic mice.

**Ang2 synergistically induces astrocyte apoptosis with high glucose.** To determine the effect of Ang2 on cell viability of astrocyte in vitro, we performed 3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide (MTT) assay and fluorescence-activated cell sorting (FACS) analysis. Ang2 leads to pericyte death under high-glucose conditions. Similarly, it aggravated astrocyte cell death under high glucose (76.8±2.2% from 85.5±3.3%, P<0.05; Figure 3a). Next, we examined whether astrocyte cell death is mediated by apoptotic pathway. Indeed, Ang2 increased apoptosis pathway with increase of Bax and cleaved poly(ADP-ribose) polymerase (PARP) under high glucose (Figure 3b). Then, astrocyte apoptosis was assessed by annexin-V/propidium iodide (PI) FACS analysis. Ang2 increases apoptotic cell population regardless of the glucose level. Of importance, high-glucose-induced astrocyte apoptosis was significantly aggravated by Ang2 (32.6±4.4% from 18.0±2.6%, P<0.05; Figure 3c). These data suggested that Ang2 induced astrocyte apoptosis especially under high-glucose conditions.

**Ang2 induces astrocyte apoptosis via GSK-3β/β-catenin pathway under high glucose.** We aimed to identify the mechanism that mediates Ang2-induced astrocyte apoptosis under high glucose. Although astrocytes were incubated for 48 h under high glucose, Ang2 (300 ng/ml) was treated for the indicated time period. We found that Ang2 induced GSK-3β activation by de-phosphorylation of GSK-3β (Ser9) and β-catenin phosphorylation (Figure 4a), which in turn led to β-catenin degradation under high glucose (Figure 4b). Then, to determine the role of the GSK-3β/β-catenin pathway for the observed Ang2-mediated astrocyte apoptosis, we treated astrocyte with GSK-3β inhibitor (SB216763, 10 μM, 1 h pre-treatment). Inhibition of GSK-3β reduced Ang2-induced β-catenin phosphorylation at 30 min (Figure 4c), and subsequent β-catenin degradation at 48 h (Figure 4d). As expected, inhibition of GSK-3β effectively attenuated Ang2-induced astrocyte apoptosis under high glucose (13.4±0.8% from 27.8±3.2%, P<0.05; Figure 4e). These data suggested that Ang2 induced astrocyte apoptosis via GSK-3β/β-catenin pathway under high-glucose conditions.

**High glucose increases integrin αvβ5 as an Ang2 receptor in astrocyte.** We aimed to reveal which receptor is responsible for mediating Ang2-induced apoptosis in astrocyte. To determine whether Tie-2 receptor, well-known receptor for Ang2, is related with Ang2-induced astrocyte apoptosis, western blot analysis (Figure 5a) and real-time PCR (Figure 5b) for Tie-2 and Tie-1 were performed on lysates obtained from human retinal microvascular endothelial cells (HRMECs) and astrocyte. As shown in previous studies, angiotensin 2,5-diphenyltetrazolium bromide (MTT) assay and fluorescence-activated cell sorting (FACS) analysis. Ang2 leads to pericyte death under high-glucose conditions. Similarly, it aggravated astrocyte cell death under high glucose (76.8±2.2% from 85.5±3.3%, P<0.05; Figure 3a). Next, we examined whether astrocyte cell death is mediated by apoptotic pathway. Indeed, Ang2 increased apoptosis pathway with increase of Bax and cleaved poly(ADP-ribose) polymerase (PARP) under high glucose (Figure 3b). Then, astrocyte apoptosis was assessed by annexin-V/propidium iodide (PI) FACS analysis. Ang2 increases apoptotic cell population regardless of the glucose level. Of importance, high-glucose-induced astrocyte apoptosis was significantly aggravated by Ang2 (32.6±4.4% from 18.0±2.6%, P<0.05; Figure 3c). These data suggested that Ang2 induced astrocyte apoptosis especially under high-glucose conditions.

**Ang2 induces astrocyte apoptosis via GSK-3β/β-catenin pathway under high glucose.** We aimed to identify the mechanism that mediates Ang2-induced astrocyte apoptosis under high glucose. Although astrocytes were incubated for 48 h under high glucose, Ang2 (300 ng/ml) was treated for the indicated time period. We found that Ang2 induced GSK-3β activation by de-phosphorylation of GSK-3β (Ser9) and β-catenin phosphorylation (Figure 4a), which in turn led to β-catenin degradation under high glucose (Figure 4b). Then, to determine the role of the GSK-3β/β-catenin pathway for the observed Ang2-mediated astrocyte apoptosis, we treated astrocyte with GSK-3β inhibitor (SB216763, 10 μM, 1 h pre-treatment). Inhibition of GSK-3β reduced Ang2-induced β-catenin phosphorylation at 30 min (Figure 4c), and subsequent β-catenin degradation at 48 h (Figure 4d). As expected, inhibition of GSK-3β effectively attenuated Ang2-induced astrocyte apoptosis under high glucose (13.4±0.8% from 27.8±3.2%, P<0.05; Figure 4e). These data suggested that Ang2 induced astrocyte apoptosis via GSK-3β/β-catenin pathway under high-glucose conditions.
FACS analysis (data now shown). Next, to determine whether integrin may serve as receptors for Ang2 in astrocyte apoptosis under high glucose, we incubated astrocyte under high glucose for 30 min with Ang2 and H-Gly-Arg-Gly-Asp-Ser-OH (GRGDS) peptides. GRGDS (0.5 mg/ml) attenuated Ang2-induced β-catenin phosphorylation (Figure 5c). This result showed that integrin signaling was involved in Ang2-induced β-catenin phosphorylation.

Next, to determine whether the high glucose changes the expression pattern of integrin, we performed quantitative RT-PCR and western blot studies for αv, β3, and β5, which are known to be expressed in astrocyte.21 Astrocyte mainly expressed αv and β5 integrin, and intriguingly, high-glucose conditions increased β5-integrin expression (Figure 5d). Although high glucose did not increase ITGαv (Figure 5e), ITGβ3 (Figure 5f) mRNA levels for 48 h, it significantly increased ITGβ5 mRNA level (P = 0.002 by one-way ANOVA, 24 h: 1.24 ± 0.04-fold; P < 0.05 and 48 h: 1.41 ± 0.00-fold, P = 0.002 by post hoc test, respectively; Figure 5g). On the other hand, high glucose decreased ITGβ3 mRNA (0.72 ± 0.01-fold for 48 h, P < 0.01; Supplementary Figure S2). In addition, we aimed to show direct binding of Ang2 to integrin αvβ5 as αv is an exclusive partner for β5. Indeed, Ang2 was shown to directly bind to integrin αvβ5 in co-immunoprecipitation assay (Figure 5h). These data suggested that high-glucose conditions increased integrin αvβ5 as a receptor for Ang2 in astrocyte.

Ang2-induced astrocyte apoptosis is inhibited by suppression of αvβ5 integrin. To determine which integrin subunit is responsible for Ang2-induced astrocyte apoptosis, we screened the integrin α subunits (α1-6 and αv). Integrin α3- and αv-blocking antibodies attenuated Ang2-induced β-catenin phosphorylation (Figure 6a). To further explore the precise integrin complex, we tested integrin α3-, αv-, and β1-blocking antibodies. Only integrin αv-blocking antibody significantly prevented Ang2-induced β-catenin degradation (Figures 6b and d). Indeed, integrin α3- and β1-blocking antibodies did not affect Ang2-induced astrocyte apoptosis (Figures 6c and e). Thus, we could narrow down the candidate to αv and its counterpart subunits β3 and β5. Same experimental procedures were conducted with αvβ3- and αvβ5-integrin-blocking antibodies, and Ang2-induced β-catenin degradation was inhibited only by blocking αvβ5 integrin (Figure 6f). Suppression of αvβ5 integrin effectively decreased Ang2-induced astrocyte apoptosis (19.3 ± 1.4% from 25.2 ± 1.2%, P < 0.05; Figure 6g).

Inhibition of αvβ5 integrin reduces astrocyte loss in diabetic retina. On the basis of in vitro experiments, we next
intravitreally injected 1 μg of anti-αvβ5-integrin antibodies to diabetic mice 2 weeks after STZ induction. One week after intravitreal injection, the isolated retinas were stained with GFAP for astrocyte evaluation (Figure 7a). In vivo, intravitreal injection of anti-αvβ5-integrin antibody effectively reduced astrocyte loss in diabetic retina (128.3 ± 16.4%) compared to the loss in PBS-injected diabetic mice (53.1 ± 8.6%, P = 0.003; Figure 7b). These in vivo data suggested that astrocyte loss occurred via αvβ5 integrin in diabetic retina.

In summary, we demonstrated that Ang2 induced astrocyte apoptosis via αvβ5 integrin in diabetic retina.

Discussion
In this study, we demonstrated that vascular leakage occurred in the diabetic retina as early as 3 weeks after diabetic
induction in mice. Interestingly, the vascular leakage in the early DR was accompanied with loss of astrocytic endfeet. In terms of the neurovascular unit, astrocyte loss could contribute to vascular leakage in the retina. Of importance, our results showed that inhibition of Ang2 effectively attenuated both astrocyte loss and vascular leakage in the early DR. Recently, we demonstrated that Ang2 induced pericyte loss via integrin signaling in DR.\(^{16}\) Although pericyte loss is an early characteristic change in DR, vascular leakage can occur even before the pericyte loss in diabetic mice.\(^{5}\) Thus, we postulated that astrocyte, as a component of neurovascular unit in retina along endothelial cell and pericyte, could play an important role in early vascular leakage in diabetic retina.

The early glial change in the diabetic retina has been described in diabetic animal models.\(^{6,7,15,22-24}\) Retinal neuroglial abnormalities are observed predominantly in the inner retina before the characteristic vascular lesions are observed.\(^{7}\) In diabetic retina, it has been observed that Müller cells acquire strong GFAP immunoreactivity throughout the retina (reactive gliosis) later than astrocyte change, whereas astrocyte progressively decreased in number and GFAP immunoreactivity.\(^{6,7,15}\) However, there was no study to investigate the role of astrocyte loss in diabetic retinal vascular leakage in terms of neurovascular unit. Importantly, the molecular mechanism of astrocyte loss in diabetes has not been elucidated yet. Thus, we approached with this concept and also suggested that Ang2-induced astrocyte apoptosis via integrin signaling as the precise molecular mechanism of astrocyte loss in DR.

Ang2 induced astrocyte loss by apoptotic mechanism. We focused on the integrin as a receptor for Ang2 in astrocyte, since astrocyte lacked the expression of Tie-2, a known receptor for Ang2.\(^{20,21}\) Indeed, Ang2 could bind to integrin \(\alpha3\beta1, \alpha4\beta5, \) and \(\alpha5\beta1.\)\(^{16,20}\) Interestingly, integrin \(\alpha3\) or \(\beta1\)-blocking antibodies did not affect Ang2-induced astrocyte apoptosis, whereas they mediated Ang2-induced pericyte apoptosis.\(^{16}\) Because we showed integrin \(\beta1\) was not responsible to Ang2-induced astrocyte apoptosis (Figures 6d and e), we could rule out many integrin \(\alpha\) subtypes and focus on the integrin \(\alpha\) complex. Only \(\alpha\beta5\) integrin, not \(\alpha\beta3\) integrin, could mediate Ang2-induced astrocyte apoptosis. Although \(\alpha\) integrin did not change significantly, high glucose changed integrin subtype of astrocyte from \(\beta8\) to \(\beta5\), which was responsible for Ang2-mediated astrocyte apoptosis. Because \(\alpha\) integrin is the only \(\alpha\) subtype for the integrin heterodimer with \(\beta5\) subtype,\(^{25,26}\) the increase of \(\beta5\) subtype implied the increase of \(\alpha\beta5\) integrin. In addition, astrocyte mainly expressed \(\alpha\) and \(\beta5\) integrins as previously reported.\(^{21,27}\) We confirmed that inhibition of \(\alpha\beta5\) integrin effectively prevented Ang2-induced astrocyte loss in vitro and in vivo. Thus, integrin \(\alpha\beta5\) could be a therapeutic target in Ang2-induced astrocyte apoptosis.

Regarding to the molecular mechanism of Ang2-induced astrocyte apoptosis, we demonstrated that Ang2 activated GSK-3\(\beta\) and subsequently induced \(\beta\)-catenin phosphorylation and degradation. In addition, we showed that GSK-3\(\beta\)-specific inhibitor blocked Ang2-induced astrocyte apoptosis. Inhibition of GSK-3\(\beta\) has been suggested as a therapeutic target in many disease including diabetes and Alzheimer’s disease.\(^{28,29}\) Thus, we suggest that it could also be a therapeutic target in diabetic retina. Furthermore, nuclear translocation of \(\beta\)-catenin is critical to the activation of
TCF/β-catenin target genes, including survivin, cyclin D1, and c-myc. The target genes, β-catenin, survivin, c-Myc, and Cyclin D1 mRNA, significantly decreased in astrocytes treated with Ang2 under high glucose (data not shown). Because survivin is a member of the inhibitor of apoptosis family of protein, decrease of β-catenin can lead to cellular apoptosis.30

The limitation of our study is the use of single-STZ-diabetic model. Previously, the most commonly used mouse models with diabetes are induced by chemical toxins such as STZ or alloxan.31 This approach replicates some of the early features of DR and has the advantage that the onset of diabetes can be defined as the time of STZ injection. However, toxin-induced diabetes in mice has been less successful because of strain-dependent resistance to STZ.32 In addition, DR features could be compounded by inflammatory effect of STZ. Despite the drawbacks of STZ-diabetic mice model, we showed high enough glucose levels during experimental periods (Figure 2g). Recently, the availability of the Ins2Akita mouse line enables to use diabetic mice without STZ or toxins.33 Interestingly, this Ins2Akita mice also showed decreased GFAP immunoreactivity in astrocytes similar to our observation although there was no explanation about molecular mechanism. Thus, further study using Ins2Akita mice about Ang2 and its role in astrocyte loss via αvβ5-integrin signaling could strengthen our study.

**Figure 4** Ang2 induces astrocyte apoptosis via GSK-3β/β-catenin pathway under high glucose (HG; 25 mM glucose). Although astrocytes were incubated for 48 h under HG, Ang2 (300 ng/ml) was treated for the indicated time period. (a) Western blot analysis for phospho-GSK-3β (Ser9) and phosphor-β-catenin (Thr41/Ser45) were performed on lysates obtained from astrocytes treated with Ang2 for 15, 30, and 60 min under HG (48 h). (b) Western blot analysis for β-catenin was performed on lysates obtained from astrocytes treated with Ang2 for 24 and 48 h under total 48 h of HG. (c) After 48 h of HG incubation, SB216763 (GSK-3β inhibitor, 10 μM) was pretreated for 1 h. Then, Ang2 was treated for 30 min. Western blot analysis was performed for phospho-GSK-3β (Ser9) and phosphor-β-catenin (Thr41/Ser45). (d) and (e) Astrocytes were incubated under HG with either Ang2 or SB 216764 for 48 h. (d) Western blot analysis for β-catenin was performed. (e) Apoptotic cell counts were assessed by FACS analysis. The bar graph represents mean ± S.E.M. of three independent experiments. *P < 0.05 by Student’s t-test. Data represent three independent experiments. β-Tubulin was used as a loading control.
In this study, we provided the evidence for the precise mechanism on the Ang2-induced astrocyte apoptosis under high glucose. These molecular mechanisms gave us the insight for the therapeutic target of astrocyte loss in diabetic retina. In addition, high glucose increases Ang2 in HRMECs and the diabetic retina. Thus, inhibition of each steps of Ang2/ integrin αvβ5/GSK-3β axis could be a potential therapeutic target to treat vascular leakage in early DR.

**Figure 5** High glucose increases integrin αvβ5 as an Ang2 receptor in astrocyte. (a) Western blot for Tie-2 and Tie-1 expression were performed on lysates obtained from HRMECs and astrocytes. (b) TIE2 and TIE1 mRNA transcriptions were assessed by quantitative RT-PCR. TIE2 and TIE1 mRNA levels were normalized to β-actin mRNA and reported as fold induction compared to HRMECs. *P < 0.001 by Student’s t-test. (c) Western blot analysis for phosphor-β-catenin (Thr41/Ser45) and β-catenin were performed on lysates obtained from astrocytes treated with Ang2 (300 ng/ml) or GRGDSP (0.5 mg/ml) for 30 min after 48 h of 25 mM high-glucose (HG) incubation. (d) Western blot analysis for integrin αv, β3, and β5 were performed on lysates obtained from astrocytes under HG for 48 h. β-Tubulin was used as a loading control. Data represent three independent experiments. ITGαv (e), ITGβ3 (f), and ITGβ5 (g) mRNA transcriptions were assessed and normalized to β-actin mRNA by quantitative RT-PCR. All mRNA levels were reported as fold induction compared to normal glucose (NG, 5 mM). *P < 0.05 by Student’s t-test. (h) After incubation of Ang2 (500 ng), integrin αvβ5 (500 ng) and integrin αvβ5 antibody (2 μg), the immune complexes were co-immunoprecipitated to show direct binding of Ang2 to integrin αvβ5. Then, they were analyzed for Ang2 and integrin αv. Same amounts of recombinant Ang2 and integrin αvβ5 were used as an input. Con, control.
Ang2-induced astrocyte apoptosis is inhibited by suppression of αvβ5 integrin. (a) Western blot analyses for phosphor-β-catenin (Thr41/Ser45) and β-catenin were performed on lysates obtained from astrocytes treated with Ang2 (300 ng/ml) or various integrin-blocking antibodies (10 μg/ml, α1, α2, α3, α4, α5, α6, and αv) under 25 mM high glucose (HG) for 30 min. (b and c) Astrocytes were incubated under HG with Ang2 and anti-integrin α3 or αv antibodies for 48 h. (b) Western blot analysis for β-catenin was performed (ImageJ quantification; N = 3, mean ± S.E.M.). (c) Astrocyte apoptosis with anti-integrin α3 antibody was analyzed by FACS and expressed as the percentage of apoptotic cells in total cell populations. (d and e) Astrocytes were incubated under HG with Ang2 and anti-integrin β1 antibody (10 μg/ml) for 48 h. (d) Western blot analysis for β-catenin was performed. β-Tubulin was used as a loading control. Data represent three independent experiments. (e) Astrocyte apoptosis with anti-integrin β1 antibody was analyzed by FACS and expressed as the percentage of apoptotic cells in total cell populations. (f) Astrocytes were incubated under HG with Ang2 and anti-integrin αvβ3 or αvβ5 antibodies (10 μg/ml) for 48 h. (f) Western blot analysis for β-catenin was performed. β-Tubulin was used as a loading control. Data represent three independent experiments. (g) Astrocyte apoptosis with anti-integrin αvβ5 antibody was analyzed by FACS and expressed as the percentage of apoptotic cells in total cell populations.

*P < 0.05, #P > 0.05 compared with Ang2 treatment by Student’s t-test.
In conclusion, we demonstrated that Ang2 induced astrocyte loss and vascular leakage in early DR. Ang2 induced astrocyte apoptosis via GSK-3β/β-catenin pathway under high glucose. High glucose increased αvβ5 in astrocyte. Furthermore, we showed that Ang2-induced astrocyte apoptosis was effectively attenuated by blocking αvβ5 integrin both in vitro and in vivo. Taken together, Ang2 induced astrocyte apoptosis via αvβ5-integrin signaling contributed to the vascular leakage in the early diabetic retina. We suggest that glycemic control or blocking Ang2/integrin signaling could be a potential therapeutic target to prevent astrocyte loss and vascular leakage in early DR.

**Materials and Methods**

**Cell cultures.** HRMECs (Applied Cell Biology Research Institute, Kirkland, WA, USA) and human brain astrocytes (Applied Cell Biology Research Institute) were maintained in M199 medium and DMEM with 20% FBS containing growth factors (HyClone, Logan, UT, USA), respectively. All cells were cultured at 37 °C in an incubator with a humidified atmosphere of 5% CO2.

**Reagents and antibodies.** Recombinant human Ang2, human integrin αvβ5, phycoerythrin (PE)-conjugated anti-endothelial-specific receptor tyrosine kinase 2 (Tie-2) mouse IgG antibody, mouse Ang2 ELISA kit, mouse VEGF ELISA kit, human phospho-kinase array kit, anti-integrin αvβ3, and anti-integrin αvβ5 (clone P5H9, MAB2528) neutralizing antibodies were purchased from R&D systems (Minneapolis, MN, USA). Mouse Ang1 ELISA kit was purchased from MyBioSource.
(San Diego, CA, USA). Anti-Bax antibody was purchased from Epitomics (Burlingame, CA, USA). Anti-phospho GSK-3β (Ser9), anti-phospho β-catenin, anti-β-catenin, and anti-PARP antibody were purchased from Cell Signaling Technology (Beverly, MA, USA). Anti-Tie-1 and peroxidase-conjugated secondary antibodies were purchased from Santa Cruz Biotechnology (Dallas, TX, USA). Anti-Tie-2 antibody, GRGDS peptide, and SB216763 were purchased from Millipore (Billerica, MA, USA). MITT (3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide), STZ, and FITC-dextran (70 kD) were purchased from Sigma-Aldrich (St. Louis, MO, USA). FITC-conjugated annexin-V/PI assay kit were purchased from BD Biosciences (Franklin Lakes, NJ, USA). Anti-GFAP, anti-integrin αV, β1, β3, and anti-Ang2 antibodies were purchased from Abcam (Cambridge, MA, USA). Anti-mouse Ang2-blocking antibody (Angy-2-1) was purchased from Adipogen (San Diego, CA, USA). Anti-integrin α3 (clone P1B5, MAB1952), anti-integrin β1 (clone 656, MAB2253), and α-integrin-blocking and IHC kit (α1-6, v) were purchased from Millipore and used for functional blocking.

Animals. All animal experiments in this study were in strict agreement with the Association for Research in Vision and Ophthalmology Statement for the Use of Animals in Ophthalmic and Vision Research and the guidelines of the Seoul National University Animal Care and Use Committee. Six-week-old, pathogen-free male C57BL/6J mice were purchased from Central Lab Animal Inc. (Seoul, Korea). Diabetes was induced by a single intraperitoneal injection of freshly prepared STZ (40 mg/kg body weight in 10 mM citrate buffer (pH 4.5) as an osmotic control for 48 h. After 2 weeks, mice were classified as diabetic or non-diabetic based on blood glucose levels (mg/dl) 4 days after STZ injection were deemed diabetic.

ELISA. Two retinas from mice were pooled (N = 6 per each group). Samples including retinas, vitreous, and lens were homogenized and lysed with brief sonication in 500 μl RIPA buffer with a complete protease inhibitor cocktail (Roche). After centrifugation at 12 000 r.p.m. for 20 min, supernatants were collected. Anti-Ang2 and VEGF levels were measured using ELISA kits according to the manufacturers’ instructions. The protein concentration was measured using a BCA protein assay kit (Pierce, Rockford, IL, USA). Anti-Ang2 (ng), Ang2 (pg), and VEGF levels (pg) were standardized to the retina protein (mg).

Quantitative and qualitative assessment of the retinal vascular leakage. To determine vascular leakage, 3-week-old STZ-induced diabetic mice were used. Deeply anesthetized mice were intravenously injected with a FITC-dextran dissolved in PBS. After 1 h of perfusion, the eyes were enucleated and fixed in 4% paraformaldehyde for 1 h. The retinas were dissected in 2 × PBS, flat-mounted and viewed by a fluorescent microscope (Eclipse 90i, Nikon, Tokyo, Japan) at a magnification of ×40 and ×100. To analyze vascular leakage quantitatively, the four representative sites of leakage at the mid-peripheral retina (0.5 μm × 0.5 μm) per each mice were selected (N = 6–7). The mid-peripheral retina was designated as the mid-one-third of the retina from optic nerve head to ciliary body. The images were imported into ImageJ (1.47v, NIH, Bethesda, MD, USA); thereby, images were adjusted for color threshold based on the automatic isodata algorithm, and the interested area with FITC was marked with red. Then, the area of red was measured. The data were expressed as vascular leakage (%), which was normalized to those of control mice.

Quantification of retinal vascular coverage by astrocyte. To determine the morphology and quantitative vascular coverage of retinal astrocyte, retinal flat mounts were immunostained against GFAP for astrocyte and IB4 for vessel. The retinas were observed by a confocal microscope (Leica TCS STED, Leica Microsystems, Wetzlar, Germany). Briefly, the eyes were enucleated and fixed in 4% paraformaldehyde for 1 h. The retinas were dissected out in 2 × PBS and incubated 100% methanol overnight at ~20 °C. Then, the retinas were blocked in PermBlock solution (0.2% Triton-X and 0.2% BSA in PBS) for 1 h at room temperature. Then, the retinas were incubated with anti-GFAP antibody (1:100) and Alexa Fluor 594-conjugated anti-IB4 antibody (1:100) in PermBlock solution overnight at 4 °C. Then, the retinas were repeatedly washed with PBS and incubated with secondary antibody (1:200) for 1 h at room temperature. After washing with PBS, the retinas were mounted with Fluoromount aqueous mounting medium (Sigma-Aldrich). The representative site of astrocyte loss at the mid-peripheral retina per each mice was selected (N = 6–8). The morphology of astrocyte was analyzed with maximal projection images of z-stack (magnification x400). For the analysis of the vascular coverage by astrocyte, the colocalized area of astrocyte and retinal vessel was divided by the area of retinal vessel (astrocyte coverage = colocalized area/vascular area). The colocalized area was calculated by using the Leica Application Suite Advanced Fluorescence (LAS AF) software (Leica Microsystems; threshold and background values are 30 and 20%, respectively). The images were imported to Imaris software (Ver.7.6.5, Bitplane, Bellatt, UK), and analyzed for the vascular area. Then, the vascular coverage by astrocyte was normalized to that of control (relative astrocyte coverage %; Supplementary Figure 3).

Intravitreal injection of anti-Ang2 and anti-integrin-neutralizing antibodies. One microliter containing 1 μg of anti-Ang2-neutralizing antibody and 1 μg of anti-integrin αV/β5 antibody (clone PS9S) was injected intravitreally under deep anesthesia at 2 weeks after diabetes induction with STZ. Sterile PBS was injected for control. After 7 days of injection, retinas were subjected to the retinal flat mount for the vascular leakage and/or astrocyte analyses.

Cell viability assay. In all experiments, 2.5 × 10^4 cells were seeded into 96-well plates. After 24 h, cells were treated with Ang2 (300 ng/ml) under normal glucose (5 mM glucose), high glucose (25 mM glucose), and high mannitol (5 mM glucose plus 20 mM mannitol) as an osmotic control for 48 h. Cell viability was determined by MTT assay according to the manufacturer’s instructions. Three independent experiments were performed for each experimental condition.

FACS analysis. In order to evaluate the apoptosis, 5 × 10^5 cells were treated with Ang2 (300 ng/ml) under normal glucose, high mannitol, and high glucose at 37 °C for 48 h. To determine the effect of integrin blocking, anti-integrin-blocking antibodies (10 μg/ml) were treated 1 h before the addition of Ang2. The cells were collected and washed two times in PBS. Cells were stained with FITC Annexin-V and PI for 15 min, and analyzed by flow cytometry. Annexin V-positive/PI-negative cells were determined to apoptotic.

Quantitative RT-PCR. Total RNA was collected and isolated from cells using RNeasy Plus Mini kit (Qiagen, Valencia, CA, USA). cDNAs were prepared from RNAs (1 μg) using 2.5 μM oligo-dT primers, 1 mM dNTPs, and MuLV reverse transcriptase. Quantitative real-time PCR (qPCR) assays were performed in qPCR master mix for SYBR Green PCR master mix (Applied Biosystems). TaqMan Fast Advanced Master Mix (Life Technologies) and specific Gene Expression Assays were performed with High Capacity RNA-to-cDNA kit (Life Technologies). Real-time PCR was performed with StepOnePlus Real-Time PCR System (Life Technologies) with TaqMan Fast Advanced Master Mix (Life Technologies) and specific Gene Expression Assays (cat. no. 4331182; Life Technologies). Product IDs of Gene Expression Assays for genes are as follows: for Angpt1; Mm00456503_m1; for Angpt2, Mm00545822_m1; for Vegfa, Mm00437306_m1; and for Rtn18s, Mm03928990_g1. All procedures were performed in accordance with the MIQE guidelines.

Immunoprecipitation and immunoblotting. For immunoprecipitation, Ang2 (500 ng) and integrin αV/β5 (500 ng) were preclared with G-Sepharose beads (Millipore) at 4 °C for 1 h. Then, the complex and anti-integrin αV/β5 antibody (2 μg) were incubated with G-Sepharose beads at 4 °C overnight. The immune complexes were collected by centrifugation and washed with buffer three times. For immunoblotting, cells were collected and lysed in RIPA buffer with a protease inhibitor cocktail. Protein lysates were resolved by SDS polyacrylamide gel and transferred onto nitrocellulose membrane. The membranes were incubated with primary antibodies (1:1000) overnight at 4 °C and secondary antibodies (1:10 000) for 1 h at room temperature. The membranes were incubated with enhanced chemiluminescent substrate (Pierce) and exposed to a film or LAS 4000 (GE Healthcare, Piscataway, NJ, USA).

Statistical analysis. Statistical analyses were performed using the standard two-tailed Student’s t-test for two groups, and one-way ANOVA and post hoc test
Conflict of Interest
The authors declare no conflict of interest.
