FACTORIZATION OF GENERALIZED THETA FUNCTIONS AT REDUCIBLE CASE

XIAOTAO SUN

INTRODUCTION

One of the problems in algebraic geometry motivated by conformal field theory is to study the behaviour of moduli space of semistable parabolic bundles on curve and its generalized theta functions when the curve degenerates to a singular curve. Let $X$ be a smooth projective curve of genus $g$, and $U_X$ be the moduli space of semistable parabolic bundles on $X$, one can define canonically an ample line bundle $\Theta_{U_X}$ (theta line bundle) on $U_X$ and the global sections $H^0(\Theta_{U_X}^k)$ are called generalized theta functions of order $k$. These definitions can be extended to the case of singular curve. Thus, when $X$ degenerates to a singular curve $X_0$, one may ask the question how to determine $H^0(\Theta_{U_{X_0}}^k)$ by generalized theta functions associated with the normalization $\tilde{X}_0$ of $X_0$. The so called fusion rules suggest that when $X_0$ is a nodal curve the space $H^0(\Theta_{U_{X_0}}^k)$ decomposes into a direct sum of spaces of generalized theta functions on moduli spaces of bundles over $\tilde{X}_0$ with new parabolic structures at the preimages of nodes. These factorizations and Verlinde formula were treated by many mathematicians from various points of view. It is obviously beyond my ability to give a complete list of contributions. According to [Be], there are roughly two approaches: infinite and finite. I understand that those using stacks and loop groups are infinite approach, and working in the category of schemes of finite type is finite approach. Our approach here should be a finite one.

When $X_0$ is irreducible with one node, a factorization theorem was proved in [NR] for rank two and generalized to arbitrary rank in [Su]. By this factorization, one can principally reduce the computation of generalized theta functions to the case of genus zero with many parabolic points. In order to have an induction machinery for the number of parabolic points, one should also prove a factorization when $X_0$ has two smooth irreducible components intersecting at a node $x_0$. This was done for rank two in [DW1] and [DW2] by analytic method. In this paper, we adopt the approach of [NR] and [Su] to prove a factorization theorem for arbitrary rank in the reducible case.

Let $I = I_1 \cup I_2 \subset X$ be a finite set of points and $U_X^I$ the moduli space of semistable parabolic bundles with parabolic structures at points $\{x\}_{x \in I}$. When $X$ degenerates to $X_0 = X_1 \cup X_2$ and points in $I_j$ $(j = 1, 2)$ degenerate to $|I_j|$ points $x \in I_j \subset X_j \setminus \{x_0\}$, we have to construct a degeneration $U_{X_0} := U_{X_1 \cup X_2}^I$ of $U_X^I$, and theta line bundle $\Theta_{U_{X_0}}$ on it. Fix a suitable ample line bundle $O(1)$ on $X_0$.
we construct the degeneration as a moduli space of ‘semistable’ parabolic torsion free sheaves on $X_0$ with parabolic structures at points $x \in I_1 \cup I_2$, and define the theta line bundle $\Theta_{U_{X_0}}$ on it. Our main observation here is that we need a ‘new semistability’ (see definition 1.3) to construct the correct degeneration of $U_{X_0}^k$. But in whole paper, this ‘new semistability’ is simply called semistable. It should not cause any confusion since our ‘new semistability’ coincides with Seshadri’s semistability in [Se] when $I = \emptyset$, and coincides with the semistability of [NR] when $X_0$ is irreducible.

Let $\pi : \tilde{X}_0 \to X_0$ be the normalization of $X_0$ and $\pi^{-1}(x_0) = \{x_1, x_2\}$. Then for any $\mu = (\mu_1, \cdots, \mu_r)$ with $0 \leq \mu_1 \leq \cdots \leq \mu_1 \leq k - 1$, we can define $\vec{a}(x_j)$, $\vec{n}(x_j)$ and $\alpha_{x_j}$ $(j = 1, 2)$ by using $\mu$ (see Notation 3.1). Let

$$U_{X_j}^\mu := U_{X_j}(r, \chi_j^\mu, I_j \cup \{x_j\}, \{\vec{n}(x), \vec{a}(x)\}_{x \in I_j \cup \{x_j\}}, k)$$

be the moduli space of $s$-equivalence classes of semistable parabolic bundles $E$ of rank $r$ on $X_j$ and $\chi(E) = \chi_j^\mu$, together with parabolic structures of type $\{\vec{n}(x)\}_{x \in I_j \cup \{x_j\}}$ and weights $\{\vec{a}(x)\}_{x \in I_j \cup \{x_j\}}$ at points $\{x\}_{x \in I_j \cup \{x_j\}}$, where $\chi_j^\mu$ is also defined in Notation 3.1, which may not be integers. Thus we define $U_{X_j}^\mu$ to be empty if $\chi_j^\mu$ is not an integer. Let

$$\Theta_{U_{X_j}^\mu} := \Theta(k, \iota_j, \{\vec{n}(x), \vec{a}(x), \alpha_{x}\}_{x \in \{I_j \cup \{x_j\}, I_j \cup \{x_j\}\}}, k)$$

be the theta line bundle. Then our main result is

**Factorization Theorem.** There exists a (noncanonical) isomorphism

$$H^0(U_{X_0}, \Theta_{U_{X_0}}) \cong \bigoplus_{\mu} H^0(U_{X_1}^\mu, \Theta_{U_{X_1}^\mu}) \otimes H^0(U_{X_2}^\mu, \Theta_{U_{X_2}^\mu})$$

where $\mu = (\mu_1, \cdots, \mu_r)$ runs through the integers $0 \leq \mu_r \leq \cdots \leq \mu_1 \leq k - 1$.

§1 is devoted to construct the moduli space $U_{X_0}$ by generalizing Simpson’s construction, and construct the theta line bundle on it. Then we determine the number of irreducible components of the moduli space and proving the nonemptyness of them (see Proposition 1.4). In §2, we sketch the construction of moduli space $\mathcal{P}$ of generalized parabolic sheaves (abbreviated to GPS) and construct an ample line bundle on it. Then we introduce and study the $s$-equivalence of GPS (see Proposition 2.5), which will be needed in studying the normalization of $U_{X_0}$. In §3, we construct and study the normalization $\mathcal{P} \to U_{X_0}$, then prove the factorization theorem (Theorem 3.1). As a byproduct, we recover the main results of [NS] (see Corollary 3.1 and Remark 3.1). They have used triples in [NS] instead of GPS.

**Acknowledgements:** This work was done during my stay at FB 6 Mathematik of Universität Essen. I would like to express my hearty thanks to Prof. H. Esnault and Prof. E. Viehweg for their hospitality and encouragements. I was benefited from the stimulating mathematical atmosphere they created in their school. Prof. M.S. Narasimhan encouraged me to prove the factorization theorem at reducible case. I thank him very much for consistent supports.

§1 **Moduli space of parabolic sheaves**

Let $X_0$ be an reduced projective curve over $C$ with two smooth irreducible components $X_1$ and $X_2$ of genus $g_1$ and $g_2$ meeting at only one point $x_0$, which is the node of $X_0$. We fix a finite set $I$ of smooth points on $X_0$ and write $I = I_1 \cup I_2$, where $I_i = \{x \in I \mid x \in X_i\} (i = 1, 2)$. 

Definition 1.1. A coherent \( O_{X_0} \)-module \( E \) is called torsion free if it is pure of dimension 1, namely, for all nonzero \( O_{X_0} \)-submodules \( E_1 \subset E \), the dimension of \( \text{Supp}(E_1) \) is 1.

A coherent sheaf \( E \) is torsion free if and only if \( E_x \) has depth 1 at every \( x \in X_0 \) as a \( O_{X_0,x} \)-module. Thus \( E \) is locally free over \( X_0 \setminus \{ x_0 \} \).

Definition 1.2. We say that a torsion free sheaf \( E \) over \( X_0 \) has a quasi-parabolic structure of type \( \vec{n}(x) = (n_1(x), \cdots, n_{l_x+1}(x)) \) at \( x \in I \), if we choose a flag of subspaces

\[
E|_{\{x\}} = F_0(E)_{x} \supset F_1(E)_{x} \supset \cdots \supset F_{l_x}(E)_{x} \supset F_{l_x+1}(E)_{x} = 0
\]

such that \( n_j(x) = \dim(F_{j-1}(E)_x/F_j(E)_x) \). If, in addition, a sequence of integers called the parabolic weights

\[
0 < a_1(x) < a_2(x) < \cdots < a_{l_x+1}(x) < k
\]

are given, we call that \( E \) has a parabolic structure of type \( \vec{a}(x) \) at \( x \), with weights \( \vec{a}(x) := (a_1(x), \cdots, a_{l_x+1}(x)) \). The sheaf \( E \) is also simply called a parabolic sheaf, whose parabolic Euler characteristic is defined as

\[
\text{par}\chi(E) := \chi(E) + \frac{1}{k} \sum_{x \in I} \sum_{i=1}^{l_x+1} n_i(x)a_i(x).
\]

We will fix an ample line bundle \( O(1) \) on \( X_0 \) such that \( \text{deg}(O(1)|_{X_i}) = c_i > 0 \) \((i = 1, 2)\), for simplicity, we assume that \( O(1) = O_{X_0}(c_1y_1 + c_2y_2) \) for two fixed smooth points \( y_i \in X_i \). For any torsion free sheaf \( E \), \( P(E,n) := \chi(E(n)) \) denote its Hilbert polynomial, which has degree 1. We define the rank of \( E \) to be

\[
\text{rk}(E) := \frac{1}{\text{deg}(O(1))} \lim_{n \to \infty} \frac{P(E,n)}{n}.
\]

Let \( r_i \) denote the rank of the restriction of \( E \) to \( X_i \) \((i = 1, 2)\), then

\[
P(E,n) = (c_1r_1 + c_2r_2)n + \chi(E), \quad r(E) = \frac{c_1}{c_1 + c_2}r_1 + \frac{c_2}{c_1 + c_2}r_2.
\]

Notation 1.1. We say that \( E \) is a torsion free sheaf of rank \( r \) on \( X_0 \) if \( r_1 = r_2 = r \), otherwise it will be said of rank \( (r_1, r_2) \). We will fix in this paper the parabolic datas \( \{\vec{n}(x)\}_{x \in I}, \{\vec{a}(x)\}_{x \in I} \) and the integers: \( \chi = d + r(1 - g), \ell_1 + \ell_2, k, \)

\[
\alpha := \{0 \leq \alpha_x < k - a_{l_x+1}(x) + a_1(x)\}_{x \in I}
\]

such that

\[
(*) \quad \sum_{x \in I} \sum_{i=1}^{l_x} d_i(x)r_i(x) + r \sum_{x \in I} \alpha_x + r(\ell_1 + \ell_2) = k\chi,
\]

where \( d_i(x) = a_{i+1}(x) - a_i(x) \) and \( r_i(x) = n_1(x) + \cdots + n_i(x) \). We will choose \( c_1 \) and \( c_2 \) such that \( \ell_1 = \frac{c_1}{c_1 + c_2}(\ell_1 + \ell_2) \) and \( \ell_2 = \frac{c_2}{c_1 + c_2}(\ell_1 + \ell_2) \) become integers.
Definition 1.3. With the fixed parabolic data in Notation 1.1, and for any torsion free sheaf $F$ of rank $(r_1, r_2)$, let

$$m(F) := \frac{r(F) - r_1}{k} \sum_{x \in I_1} (a_{l_x}+1(x) + \alpha_x) + \frac{r(F) - r_2}{k} \sum_{x \in I_2} (a_{l_x}+1(x) + \alpha_x).$$

If $F$ has parabolic structures at points $x \in I$, the modified parabolic Euler characteristic and slope of $F$ are defined as

$$\par \chi_m(F) := \par \chi(F) + m(F), \quad \par \mu_m(F) := \frac{\par \chi_m(F)}{r(F)}.$$

A parabolic sheaf $E$ is called semistable (resp. stable) for $(k, \alpha, \vec{a})$ if, for any subsheaf $F \subset E$ such $E/F$ is torsion free, one has, with the induced parabolic structure,

$$\par \chi_m(F) \leq \frac{\par \chi_m(E)}{r(E)} r(F) \quad (\text{resp. <}).$$

Remark 1.1. The above semistability is independent of the choice of $\alpha$ and coincides with Seshadri’s semistability of parabolic torsion free sheaves when the curves are irreducible.

We will only consider in this section torsion free sheaves of rank $r$ with parabolic structures of type $\{\vec{n}(x)\}_{x \in I}$ and weights $\{\vec{a}(x)\}_{x \in I}$ at points $\{x\}_{x \in I}$, and construct the moduli space of semistable parabolic sheaves. Let $\mathcal{W} = \mathcal{O}_{X_0}(-N)$ and $V = \mathbb{C}^P(N)$, we consider the Quot scheme

$$\text{Quot}(V \otimes \mathcal{W}, P)(T) = \left\{ \text{T-flat quotients } V \otimes \mathcal{W} \to E \to 0 \text{ over } \right\},$$

and let $\mathcal{Q} \subset \text{Quot}(V \otimes \mathcal{W}, P)$ be the open set

$$\mathcal{Q}(T) = \left\{ V \otimes \mathcal{W} \to E \to 0, \text{ with } R^1 p_{T*}(E(N)) = 0 \text{ and } V \otimes \mathcal{O}_T \to p_{T*} E(N) \text{ induces an isomorphism } \right\}.$$

Thus we can assume (Lemma 20 of [Se], page 162) that $N$ is chosen large enough so that every semistable parabolic torsion free sheaf with Hilbert polynomial $P$ and parabolic structures of type $\{\vec{n}(x)\}_{x \in I}$, weights $\{\vec{a}(x)\}_{x \in I}$ at points $\{x\}_{x \in I}$ appears as a quotient corresponding to a point of $\mathcal{Q}$.

Let $V \otimes \mathcal{W} \to \mathcal{F} \to 0$ be the universal quotient over $X_0 \times \tilde{\mathcal{Q}}$ and $\mathcal{F}_x$ be the restriction of $\mathcal{F}$ on $\{x\} \times \tilde{\mathcal{Q}} \cong \tilde{\mathcal{Q}}$. Let $\text{Flag}_{\vec{n}(x)}(\mathcal{F}_x) \to \tilde{\mathcal{Q}}$ be the relative flag scheme of type $\vec{n}(x)$, and

$$\mathcal{R} = \times_{x \in I} \text{Flag}_{\vec{n}(x)}(\mathcal{F}_x) \to \tilde{\mathcal{Q}}$$

be the product over $\tilde{\mathcal{Q}}$, where $\tilde{\mathcal{Q}}$ is the closure of $\mathcal{Q}$ in the Quot scheme.

A (closed) point $\{p \in \mathcal{P}, \{p_{r_1}(x), p_{r_1}(x), \ldots, p_{r_{l_x}}(x)\}_{x \in I}\}$ of $\mathcal{R}$ by definition is given by a point $V \otimes \mathcal{W} \overset{p_{r_1}}{\to} E \to 0$ of the Quot scheme, together with quotients

$$\{ V \otimes \mathcal{W} \overset{p_{r_1}(x)}{\to} E \overset{p_{r_2}(x)}{\to} \mathcal{O} \to 0, \ldots, V \otimes \mathcal{W} \overset{p_{r_{l_x}}(x)}{\to} E \to 0 \}.$$
where \( r_i(x) = \text{dim}(E_{x}/F_{i}(E)_{x}) = n_1(x) + \cdots + n_i(x) \), and \( Q_{r(x)} := E_{x}, Q_{r_1(x)} := E_{x}/F_1(E)_{x}, \ldots, Q_{r_{ix}(x)} := E_{x}/F_{ix}(E)_{x} \). For large enough \( m \), we have a \( SL(V) \)-equivariant embedding

\[
\mathcal{R} \hookrightarrow \mathcal{G} = \text{Grass}_{p(m)}(V \otimes W_{m}) \times \text{Flag},
\]

where \( W_m = H^0(\mathcal{W}(m)) \), and \( \text{Flag} \) is defined to be

\[
\text{Flag} = \prod_{x \in I} \{ \text{Grass}_{r(x)}(V) \times \text{Grass}_{r_1(x)}(V) \times \cdots \times \text{Grass}_{r_{ix}(x)}(V) \},
\]

which maps a point \( (p, \{ p_{r(x)}, p_{r_1(x)}, \ldots, p_{r_{ix}(x)} \}_{x \in I}) \) of \( \mathcal{R} \) to the point

\[
(V \otimes W_{m} \xrightarrow{g} U, V \xrightarrow{g_{r(x)}} U_{r(x)}, V \xrightarrow{g_{r_1(x)}} U_{r_1(x)}, \ldots, V \xrightarrow{g_{r_{ix}(x)}} U_{r_{ix}(x)} \}_{x \in I})
\]

of \( \mathcal{G} \), where \( g := H^0(p(m)) \), \( U := H^0(E(m)) \), \( g_{r(x)} := H^0(p_{r(x)}(N)) \), \( U_{r(x)} := H^0(Q_{r(x)}) \), and \( g_{r_i(x)} := H^0(p_{r_i(x)}(N)) \), \( U_{r_i(x)} := H^0(Q_{r_i(x)}) \) \( i = 1, \ldots, l_x \).

For any rational number \( \ell \) satisfying \( c_i \ell = \ell_i + c_i k N \) \( i = 1, 2 \), we give \( \mathcal{G} \) the polarisation (using the obvious notation):

\[
\frac{\ell}{m - N} \times \prod_{x \in I} \{ \alpha_x, d_1(x), \ldots, d_{l_x}(x) \},
\]

and we have a straightforward generalisation of [NR, Proposition A.6] whose proof we omit:

**Proposition 1.1.** A point \( (p, \{ g_{r(x)}, g_{r_1(x)}, \ldots, g_{r_{ix}(x)} \}_{x \in I}) \in \mathcal{G} \) is stable (respectively, semistable) for the action of \( SL(V) \), with respect to the above polarisation (we refer to this from now on as GIT-stability), iff for all nontrivial subspaces \( H \subset V \) we have (with \( h = \text{dim} H \))

\[
\frac{\ell}{m - N} (h P(m) - P(N) \text{dim} g(H \otimes W_{m})) + \sum_{x \in I} \alpha_x (rh - P(N) \text{dim} g_{r(x)}(H))
\]

\[
+ \sum_{x \in I} \sum_{i=1}^{l_x} d_i(x)(r_i(x)h - P(N) \text{dim} g_{r_i(x)}(H)) < (\leq) 0.
\]

**Notation 1.2.** Given a point \( (p, \{ p_{r(x)}, p_{r_1(x)}, \ldots, p_{r_{ix}(x)} \}_{x \in I}) \in \mathcal{R} \), and a subsheaf \( F \) of \( E \) we denote the image of \( F \) in \( Q_{r_{ix}(x)} \) (respectively, in \( Q_{r(x)} \)) by \( Q_{r_{ix}(x)}^{F} \) (respectively, by \( Q_{r(x)}^{F} \)). Similarly, given a quotient \( E \xrightarrow{T} \mathcal{G} \rightarrow 0 \), set \( \mathcal{G}^{F}_{r_{ix}(x)} := Q_{r_{ix}(x)}/\text{Im}(\text{ker}(T)) \) (respectively, \( \mathcal{G}^{F}_{r(x)} := Q_{r(x)}/\text{Im}(\text{ker}(T)) \)).

**Proposition 1.2.** Suppose \( (p, \{ p_{r(x)}, p_{r_1(x)}, \ldots, p_{r_{ix}(x)} \}_{x \in I}) \in \mathcal{R} \) is a point such that \( E \) is torsion free. Then \( E \) is stable (respectively, semistable) iff for every subsheaf \( 0 \neq F \neq E \) we have

\[
\frac{\ell}{m - N} (\chi(F(N))P(m) - P(N)\chi(F(m))) + \sum_{x \in I} \alpha_x (r\chi(F(N)) - P(N)h^0(Q_{r(x)}^{F}))
\]

\[
+ \sum_{x \in I} \sum_{i=1}^{l_x} d_i(x)(r_i(x)\chi(F(N)) - P(N)h^0(Q_{r_i(x)}^{F})) < (\leq) 0.
\]
Proof. For any subsheaf $F$ let $LHS(F)$ denote the left-hand side of above inequality. Assume first that $E/F$ is torsion free and $F$ is of rank $(r_1, r_2)$, thus $h^0(Q_{r_i}^F) = r_i$ for $x \in I_i$ ($i = 1, 2$) and $\chi(F(m)) = (c_1 r_1 + c_2 r_2)(m - N) + \chi(F(N))$,

$$h^0(Q_{r_i}^F) = \dim(F_x/F_x \cap F_i(E)_x).$$

Let $n_i^F(x) := \dim(F_x \cap F_{i-1}(E)_x/F_x \cap F_i(E)_x)$, and note that

$$\sum_{x \in I} \sum_{i=1}^{l_x} d_i(x) r_i(x) = r \sum_{x \in I} a_{l_x+1}(x) - \sum_{x \in I} \sum_{i=1}^{l_x+1} a_i(x) n_i(x),$$

we have

$$LHS(F) = \left( \sum_{x \in I} \sum_{i=1}^{l_x} d_i(x) r_i(x) + r \sum_{x \in I} \alpha_x + r c_1 \ell + r c_2 \ell \right) \left( \chi(F) - \frac{r(F)}{r} \chi \right)$$

$$+ P(N) \left( r(F) \sum_{x \in I} \alpha_x + \frac{r(F)}{r} \sum_{x \in I} \sum_{i=1}^{l_x} d_i(x) r_i(x) \right)$$

$$- P(N) \left( r_1 \sum_{x \in I_1} \alpha_x + r_2 \sum_{x \in I_2} \alpha_x + \sum_{x \in I} \sum_{i=1}^{l_x} d_i(x) \dim(F_x/F_x \cap F_i(E)_x) \right)$$

$$= kP(N) \left( \text{par}\chi_m(F) - \frac{r(F)}{r} \text{par}\chi_m(E) \right).$$

Thus the inequality implies the (semi)stability of $E$, and the (semi)stability of $E$ implies the inequality for subsheaves $F$ such that $E/F$ torsion free.

Suppose now that $E$ is (semi)stable and $F$ any nontrivial subsheaf, let $\tau$ be the torsion of $E/F$ and $F' \subset E$ such that $\tau = F'/F$ and $E/F'$ torsion free. Then we
have $\text{LHS}(F') \leq 0$ and, if we write $\tau = \tilde{\tau} + \sum_{x \in I} \tau_x$, then

$$\text{LHS}(F) - \text{LHS}(F') = - (c_1 + c_2) r \ell h^0(\tau)$$

$$- \sum_{x \in I} \alpha_x \left( r h^0(\tau) + P(N)(h^0(Q_{r(x)}^F) - h^0(Q_{r(x)}^{F'})) \right)$$

$$- \sum_{x \in I} \sum_{i=1}^{l_x} d_i(x) \left( r_i(x) h^0(\tau) + P(N)(h^0(Q_{r(x)}^F) - h^0(Q_{r(x)}^{F'})) \right)$$

$$= -h^0(\tau) \left( \sum_{x \in I} \sum_{i=1}^{l_x} d_i(x) r_i(x) + r \sum_{x \in I} \alpha_x + rc_1 \ell + rc_2 \ell \right) -$$

$$P(N) \left( \sum_{x \in I} -\alpha_x h^0(\tau_x) + \sum_{x \in I} \sum_{i=1}^{l_x} d_i(x) (h^0(Q_{r(x)}^F) - h^0(Q_{r(x)}^{F'})) \right)$$

$$\leq -k P(N) h^0(\tau) + P(N) \sum_{x \in I} \alpha_x h^0(\tau_x) + P(N) \sum_{x \in I} \sum_{i=1}^{l_x} d_i(x) h^0(\tau_x)$$

$$= -k P(N) h^0(\tau) - P(N) \sum_{x \in I} (k - \alpha_x - a_{l_x+1}(x) + a_1(x)) h^0(\tau_x) \leq 0,$$

where we have used $h^0(Q_{r(x)}^F) - h^0(Q_{r(x)}^{F'}) = -h^0(\tau_x)$, the assumption about $\{\alpha_x\}$ and $h^0(Q_{r(x)}^F) - h^0(Q_{r(x)}^{F'}) \geq -h^0(\tau_x)$.

**Lemma 1.1.** There exists $M_1(N)$ such that for $m \geq M_1(N)$ the following holds. Suppose $(p, \{p_{r(x)}, p_{r_1(x)}, ..., p_{r_{r_2}(x)}\}_{x \in I}) \in \mathcal{R}$ is a point which is GIT-semistable then for all quotients $E \xrightarrow{T} \mathcal{G} \xrightarrow{G} 0$ we have

$$h^0(\mathcal{G}(N)) \geq \frac{1}{k} \left( (c_1 + c_2) r(\mathcal{G}) \ell + \sum_{x \in I} \alpha_x h^0(Q_{r(x)}^\mathcal{G}) + \sum_{x \in I} \sum_{i=1}^{l_x} d_i(x) h^0(Q_{r(x)}^\mathcal{G}) \right).$$

In particular, $E$ is torsion free and $V \to H^0(E(N))$ is an isomorphism.

**Proof.** Let $H = \ker\{ V \xrightarrow{H^0(p(N))} \to H^0(E(N)) \to H^0(\mathcal{G}(N)) \}$, and $F \subset E$ the subsheaf generated by $H$. Since all these $F$ are in a bounded family, $\text{dim}\ g(H \otimes W_m) = h^0(F(m)) = \chi(F(m))$ for $m$ large enough. Thus there exists $M_1(N)$ such that for $m \geq M_1(N)$ the inequality of Proposition 1.1 implies (with $h = \text{dim}(H)$)

$$(c_1 + c_2) \ell (r h - r(F) P(N)) + \sum_{x \in I} \alpha_x \left( r h - P(N) h^0(Q_{r(x)}^F) \right)$$

$$+ \sum_{x \in I} \sum_{i=1}^{l_x} d_i(x) \left( r_i(x) h - P(N) h^0(Q_{r(x)}^F) \right) \leq 0,$$

where we used that $g_{r(x)}(H) = h^0(Q_{r(x)}^F)$ and $g_{r_1(x)}(H) = h^0(Q_{r(x)}^F)$. Now using the following inequalities

$$h^0(P(N) - h^0(G(N))) = h^0(Q_{r(x)}^F) \geq h^0(Q_{r(x)}^G),$$

for $m \geq M_1(N)$. Therefore,
we get the inequality
\[
h^0(\mathcal{G}(N)) \geq \frac{1}{k} \left( (c_1 + c_2) r(\mathcal{G}) \ell + \sum_{x \in I} \alpha_x h^0(Q_{r_{\ell}}(x)) + \sum_{x \in I} \sum_{i = 1}^{l_x} d_i(x) h^0(Q_{r_{i(x)}}) \right).
\]

Now we show that \( V \to H^0(E(N)) \) is an isomorphism. That it is injective is easy to see: let \( H \) be its kernel, then \( g(\mathcal{H} \otimes W_m) = 0 \), \( g_{r(x)}(H) = 0 \) and \( g_{r_i(x)}(H) = 0 \), one sees that \( h = 0 \) from Proposition 1.1. To see it being surjective, it is enough to show that one can choose \( N \) such that \( H^1(E(N)) = 0 \) for all such \( E \). If \( H^1(E(N)) \) is nontrivial, then there is a nontrivial quotient \( E(N) \to L \subset \omega_{X_0} \) by Serre duality, and thus
\[
h^0(\omega_{X_0}) \geq h^0(L) \geq (c_1 + c_2) N + B,
\]
where \( B \) is a constant independent of \( E \), we choose \( N \) such that \( H^1(E(N)) = 0 \) for all GIT-semistable points.

Let \( \tau = \text{Tor}(E), \mathcal{G} = E/\tau \) and applying the above inequality, noting that \( h^0(\mathcal{G}(N)) = P(N) - h^0(\tau), h^0(Q_{r_{\ell}}(x)) = r - h^0(Q_{r_{\ell}}(x)) \) and \( h^0(Q_{r_{i(x)}}) = r_{i(x)} - h^0(Q_{r_{i(x)}}) \), we have
\[
h^0(\tau) \leq \sum_{x \in I} (\alpha_x + a_{l_x + 1}(x) - a_1(x)) h^0(\tau_x),
\]
by which one can conclude that \( \tau = 0 \) since \( \alpha_x < k - a_{l_x + 1}(x) + a_1(x) \).

**Proposition 1.3.** There exist integers \( N > 0 \) and \( M(N) > 0 \) such that for \( m \geq M(N) \) the following is true. A point \( (p, \{p_{r(x)}(x), p_{r_1(x)}, \ldots, p_{r_{l_x}(x)}\}_{x \in I}) \in \mathcal{R} \) is GIT-stable (respectively, GIT-semistable) iff the quotient \( E \) is torsion free and a stable (respectively, semistable) sheaf, the map \( V \to H^0(E(N)) \) is an isomorphism.

**Proof.** If \( (p, \{p_{r(x)}(x), p_{r_1(x)}, \ldots, p_{r_{l_x}(x)}\}_{x \in I}) \in \mathcal{R} \) is GIT-stable (GIT-semistable), by Lemma 1.1, \( E \) is torsion free and \( V \to H^0(E(N)) \) is an isomorphism. For any subsheaf \( F \subset E \) with \( E/F \) torsion free, let \( H \subset V \) be the inverse image of \( H^0(F(N)) \) and \( h = \dim(H) \), we have \( \chi(F(N)) P(m) - P(N) \chi(F(m)) \leq h P(m) - P(N) h^0(F(m)) \) for \( m > N \) (note that \( h^1(F(N)) \geq h^1(F(m)) \)). Thus
\[
\frac{\ell}{m - N} \left( \chi(F(N)) P(m) - P(N) \chi(F(m)) \right) + \sum_{x \in I} \alpha_x r_x \left( \chi(F(N)) - P(N) h^0(Q_{r_{\ell}}(x)) \right)
+ \sum_{x \in I} \sum_{i = 1}^{l_x} d_i(x) r_{i(x)} \chi(F(N)) - P(N) h^0(Q_{r_{i(x)}}(x)) \leq
\frac{\ell}{m - N} \left( h P(m) - P(N) \dim g(H \otimes W_m) \right) + \sum_{x \in I} \alpha_x \left( r_x - P(N) \dim g_{r(x)}(H) \right)
+ \sum_{x \in I} \sum_{i = 1}^{l_x} d_i(x) \left( r_{i(x)} h - P(N) \dim g_{r_{i(x)}}(H) \right)
\]
since \( g(H \otimes W_m) \leq h^0(F(m)), g_{r(x)}(H) \leq h^0(Q_{r_{\ell}}(x)) \) and \( g_{r_{i(x)}}(H) \leq h^0(Q_{r_{i(x)}}(x)) \) (the inequalities are strict when \( h = 0 \)). By Proposition 1.1 and Proposition 1.2,
$E$ is stable (respectively, semistable) if the point is GIT stable (respectively, GIT semistable).

The proof of another direction is similar to [NR], one can prove the similar Lemma A.9 and Lemma A.12 of [NR] by just modifying notation.

One can imitate [Se] (Théorème 12, page 71) to show that given a semistable parabolic sheaf $E$, there exists a filtration of $E$

$$0 = E_{n+1} \subset E_n \subset \cdots \subset E_2 \subset E_1 \subset E_0 = E$$

such that $E_i/E_{i+1}$ $(1 \leq i \leq n)$ are stable parabolic sheaves with the constant slope $\text{par}\mu_m(E)$, and the isomorphic class of semistable parabolic sheaf

$$\text{gr}(E) := \bigoplus_{i} E_i/E_{i+1}$$

is independent of the filtration. Two semistable parabolic sheaves $E$ and $E'$ are called $s$-equivalent if $\text{gr}(E) \cong \text{gr}(E')$.

**Theorem 1.1.** For given datas in Notation 1.1 satisfying (∗), there exists a reduced, seminormal projective scheme

$$U_{X_0} := U_{X_0}(r, \chi, I_1 \cup I_2, \{\vec{n}(x), \vec{a}(x), \alpha_x\}_{x \in I}, \mathcal{O}(1), k),$$

which is the coarse moduli space of $s$-equivalence classes of semistable parabolic sheaves $E$ of rank $r$ and $\chi(E) = \chi$ with parabolic structures of type $\{\vec{n}(x)\}_{x \in I}$ and weights $\{\vec{a}(x)\}_{x \in I}$ at points $\{x\}_{x \in I}$. The moduli space $U_{X_0}$ has at most $r + 1$ irreducible components.

**Proof.** Let $\mathcal{R}^{ss}$ ($\mathcal{R}^s$) be the open set of $\mathcal{R}$ whose points correspond to semistable (stable) parabolic sheaves on $X_0$. Then, by Proposition 1.3, the quotient

$$\varphi : \mathcal{R}^{ss} \to U_{X_0} := \mathcal{R}^{ss}/\!/SL(V)$$

exists as a projective scheme. That $U_{X_0}$ is reduced and seminormal follow from the properties of $\mathcal{R}^{ss}$ (see [Fa] [Se] [Su]).

Consider the dense open set $\mathcal{R}_0 \subset \mathcal{R}^{ss}$ consists of locally free sheaves, for each $F \in \mathcal{R}_0$, let $F_1$ and $F_2$ be the restrictions of $F$ to $X_1$ and $X_2$, we have

$$(1.1) \quad 0 \to F_1(-x_0) \to F \to F_2 \to 0.$$  

By the semistability of $F$ and $\text{par}\chi_m(F_1) + \text{par}\chi_m(F_2) = \text{par}\chi_m(F) + r$, we have

$$\frac{c_1}{c_1 + c_2} \text{par}\chi_m(F) \leq \text{par}\chi_m(F_1) \leq \frac{c_1}{c_1 + c_2} \text{par}\chi_m(F) + r,$$

$$\frac{c_2}{c_1 + c_2} \text{par}\chi_m(F) \leq \text{par}\chi_m(F_2) \leq \frac{c_2}{c_1 + c_2} \text{par}\chi_m(F) + r.$$  

Let $\chi_1$, $\chi_2$ denote $\chi(F_1)$, $\chi(F_2)$, and $n_j$ denote (for $j = 1, 2$)

$$(1.2) \quad \frac{1}{k} \left( \sum_i \sum_x d_i(x)r_i(x) + r \sum_x \alpha_x + r\ell_j \right),$$
we can rewrite the above inequalities into

\[(1.3) \quad n_1 \leq \chi_1 \leq n_1 + r, \quad n_2 \leq \chi_2 \leq n_2 + r.\]

There are at most \(r + 1\) possible choices of \((\chi_1, \chi_2)\) satisfying \((1.3)\) and \(\chi_1 + \chi_2 = \chi + r\), each of the choices corresponds an irreducible component of \(U_{X_0}\).

For any \(\chi_1, \chi_2\) satisfying \((1.3)\), let \(U_{X_1}\) (resp. \(U_{X_2}\)) be the moduli space of semistable parabolic bundles of rank \(r\) and Euler characteristic \(\chi_1\) (resp. \(\chi_2\)), with parabolic structures of type \(\{\tilde{a}(x)\}_{x \in I_1}\) (resp. \(\{\tilde{a}(x)\}_{x \in I_2}\)) and weights \(\{\tilde{a}(x)\}_{x \in I_1}\) (resp. \(\{x\}_{x \in I_2}\)). Then we have

**Proposition 1.4.** Suppose that \(U_{X_1}\) and \(U_{X_2}\) are not empty. Then there exists a semistable parabolic vector bundle \(E\) on \(X_0\), with parabolic structures of type \(\{\tilde{a}(x)\}_{x \in I}\) and weights \(\{\tilde{a}(x)\}_{x \in I}\) at points \(\{x\}_{x \in I}\), such that

\[E|_{X_1} \in U_{X_1}, \quad E|_{X_2} \in U_{X_2}.\]

Moreover, if \(n_1 \leq \chi_1 < n_1 + r\) and \(n_2 \leq \chi_2 < n_2 + r\), \(E\) is stable whenever one of \(E_1\) and \(E_2\) is stable.

**Proof.** For any \(E_1 \in U_{X_1}\) and \(E_2 \in U_{X_2}\), one can glue them by any isomorphism at \(x_0\) into a vector bundle \(E\) on \(X_0\) with the described parabolic structures at points \(\{x\}_{x \in I}\) such that \(E|_{X_1} = E_1\) and \(E|_{X_2} = E_2\). We will show that \(E\) is semistable.

For any subsheaf \(F \subset E\) of rank \((r_1, r_2)\) such that \(E/F\) torsion free, we have the commutative diagram

\[
\begin{array}{cccccc}
0 & \longrightarrow & F_1 & \longrightarrow & F & \longrightarrow & F_2 & \longrightarrow & 0 \\
\downarrow & & \downarrow & & \downarrow & & \downarrow & & \\
0 & \longrightarrow & E_1(-x_0) & \longrightarrow & E & \longrightarrow & E_2 & \longrightarrow & 0
\end{array}
\]

where \(F_2\) is the image of \(F\) under \(E \rightarrow E_2 \rightarrow 0\) and \(F_1\) is the kernel of \(F \rightarrow F_2 \rightarrow 0\). One sees easily that \(F_1\) and \(F_2\) are of rank \((r_1, 0)\) and \((0, r_2)\) torsion free sheaves. From the above diagram (1.4), we have the following equalities

\[
\frac{\text{par}\chi_m(E)}{r} - \frac{\text{par}\chi_m(F)}{r(F)}
= \frac{\text{par}\chi_m(E_1(-x_0))}{r} - \frac{\text{par}\chi_m(F_1)}{r(F)} + \frac{\text{par}\chi_m(E_2)}{r} - \frac{\text{par}\chi_m(F_2)}{r(F)}
= a_1 r_1 \cdot \text{par}\chi_m(E_1(-x_0)) - r \cdot \text{par}\chi_m(F_1) + a_2 r_2 \cdot \text{par}\chi_m(E_1(-x_0))
+ \frac{a_2 r_2 \cdot \text{par}\chi_m(E_2) - r \cdot \text{par}\chi_m(F_2) + a_1 r_1 \cdot \text{par}\chi_m(E_2)}{r(F) \cdot r}
= \frac{r_1}{r(F)}(\text{par}\mu_m(E_1(-x_0)) - \text{par}\mu_m(F_1)) + \frac{r_2}{r(F)}(\text{par}\mu_m(E_2) - \text{par}\mu_m(F_2))
+ \frac{a_2(r_2 - r_1)\text{par}\chi_m(E_1(-x_0)) + a_1(r_1 - r_2)\text{par}\chi_m(E_2)}{r(F) \cdot r}
= \frac{r_1}{r(F)}(\text{par}\mu(E_1(-x_0)) - \text{par}\mu(F_1)) + \frac{r_2}{r(F)}(\text{par}\mu(E_2) - \text{par}\mu(F_2))
+ (r_1 - r_2)\left(\frac{c_1}{c_1 + c_2}\text{par}\chi_m(E) + r - \text{par}\chi_m(E_1)\right)
+ \frac{(r_1 - r_2)\left(\frac{c_1}{c_1 + c_2}\text{par}\chi_m(E) + r - \text{par}\chi_m(E_1)\right)}{r(F)}
\]
where we used the notation \(a_1 := \frac{c_1}{c_1 + c_2}\) and \(a_2 := \frac{c_2}{c_1 + c_2}\), the last equality follows that
\[
\frac{m(E_1(-x_0))}{r} - \frac{m(F_1)}{r_1} = 0, \quad \frac{m(E_2)}{r} - \frac{m(F_2)}{r_2} = 0.
\]

Similarly, if we use the following diagram
\[
\begin{array}{cccccc}
0 & \longrightarrow & F_2 & \longrightarrow & F & \longrightarrow & F_1 & \longrightarrow & 0 \\
\downarrow & & \downarrow & & \downarrow & \downarrow & \downarrow & \downarrow & \\
0 & \longrightarrow & E_2(-x_0) & \longrightarrow & E & \longrightarrow & E_1 & \longrightarrow & 0
\end{array}
\]

we will get the equality
\[
\frac{\text{par} \chi m(E)}{r} - \frac{\text{par} \chi m(F)}{r(F)} = \frac{r_2}{r(F)}(\text{par} \mu(E_2(-x_0)) - \text{par} \mu(F_2)) \\
+ \frac{r_1}{r(F)}(\text{par} \mu(E_1) - \text{par} \mu(F_1)) \\
+ \frac{(r_2 - r_1)(\frac{c_2}{c_1 + c_2} \text{par} \chi m(E) + r - \text{par} \chi m(E_2))}{r(F) \cdot r}
\]

Thus we always have the inequality
\[
\frac{\text{par} \chi m(E)}{r} - \frac{\text{par} \chi m(F)}{r(F)} \geq 0
\]

and the equality implies that \(r_1 = r_2\) and \(E_1, E_2\) are both unstable. This proves the proposition.

By a family of parabolic sheaves of rank \(r\) and Euler characteristic \(\chi\) with parabolic structures of type \(\{\vec{n}(x)\}_{x \in I}\) and weights \(\{\vec{a}(x)\}_{x \in I}\) parametrized by \(T\), we mean a sheaf \(\mathcal{F}\) on \(X_0 \times T\), flat over \(T\), and torsion free with rank \(r\) and Euler characteristic \(\chi\) on \(X_0 \times \{t\}\) for every \(t \in T\), together with, for each \(x \in I\), a flag
\[
\mathcal{F}_{\{x\} \times T} = F_0(\mathcal{F}_{\{x\} \times T}) \supset F_1(\mathcal{F}_{\{x\} \times T}) \supset \cdots \supset F_{l_x}(\mathcal{F}_{\{x\} \times T}) \supset F_{l_x+1}(\mathcal{F}_{\{x\} \times T}) = 0
\]
of subbundles of type \(\vec{n}(x)\) and weights \(\vec{a}(x)\). Let \(\mathcal{Q}_{\{x\} \times T, i}\) denote the quotients \(\mathcal{F}_{\{x\} \times T} / F_i(\mathcal{F}_{\{x\} \times T})\), then we define a line bundle \(\Theta_{\mathcal{F}}\) on \(T\) to be
\[
(det R\pi_T \mathcal{F})^k \otimes \bigotimes_{x \in I} (det \mathcal{F}_{\{x\} \times T})^{a_x} \otimes \bigotimes_{i=1}^{l_x} (det \mathcal{Q}_{\{x\} \times T, i})^{d_i(x)} \otimes \bigotimes_{j=1}^{2} (det \mathcal{F}_{\{y_j\} \times T})^{\ell_j}
\]
where \(\pi_T\) is the projection \(X_0 \times T \rightarrow T\), and \(det R\pi_T \mathcal{F}\) is the determinant bundle defined as
\[
(det R\pi_T \mathcal{F})_t := (det H^0(X, \mathcal{F}_t))^{-1} \otimes (det H^1(X, \mathcal{F}_t)).
\]
Theorem 1.2. There is an unique ample line bundle $\Theta_{U_{X_0}} = \Theta(k, \ell_1, \ell_2, a, n, \alpha, I)$ on $U_{X_0}$ such that for any given family of semistable parabolic sheaf $F$ parametrised by $T$, we have $\phi_T^* \Theta_{U_{X_0}} = \Theta_F$, where $\phi_T$ is the induced map $T \to U_{X_0}$.

Proof. By using the descendant lemma (see the next Lemma 1.2), we will show that the line bundle $\Theta_{\mathcal{R}_{ss}} := \Theta$ on $\mathcal{R}_{ss}$ descends to the required ample line $\Theta_{U_{X_0}}$, where $\mathcal{E}$ is a universal quotient over $X_0 \times \mathcal{R}_{ss}$.

We known that the stabilizer $\text{stab}(q) = \lambda \cdot \text{id}$ for $q \in \mathcal{R}^s$, which acts on $\Theta_{\mathcal{R}_{ss}}$ via

$$\lambda^{-k} \chi + \sum_{x \in I} t_x d_i(x) r_i(x) + r \sum_{x \in I} \alpha_x + r(\ell_1 + \ell_2) = \lambda^0 = 1.$$ 

If $q \in \mathcal{R}_{ss} \setminus \mathcal{R}^s$ with closed orbit, we known that

$$\mathcal{E}_q = m_1 E_1 \oplus m_2 E_2 \oplus \cdots \oplus m_t E_t$$

with $\text{par}_m(E_j) = \text{par}_m(\mathcal{E}_q)$, which means that (if assuming $E_j$ of rank $(r_1, r_2)$)

$$-k \chi(E_j) + r_1 \sum_{x \in I_1} \alpha_x + r_2 \sum_{x \in I_2} \alpha_x + \sum_{x \in I} d_i(x) \text{dim} \frac{E_j x}{E_j x \cap F_i(E)x} + r_1 \ell_1 + r_2 \ell_2 = 0.$$ 

Thus $(\lambda_1 \cdot \text{id}_{m_1}, \ldots, \lambda_t \cdot \text{id}_{m_t}) \in \text{stab}(q) = GL(m_1) \times \cdots \times GL(m_t)$ acts trivially on $\Theta_{\mathcal{R}_{ss}}$, which implies that the $\text{stab}(q)$ acts trivially on $\Theta_{\mathcal{R}_{ss}}$ and thus descends to a line bundle $\Theta_{U_{X_0}}$ having the required universal property.

To show the ampleness of $\Theta_{U_{X_0}}$, noting that $\text{det} R \pi_{\mathcal{R}_{ss}} \mathcal{E}(N)$ is trivial and

$$\text{det} R \pi_{\mathcal{R}_{ss}} \mathcal{E} = (\text{det} \mathcal{E}_{y_1})^{c_1 N} \otimes (\text{det} \mathcal{E}_{y_2})^{c_2 N} \otimes \text{det} R \pi_{\mathcal{R}_{ss}} \mathcal{E}(N),$$

we see that the restriction of the polarization to $\mathcal{R}_{ss}$ is

$$(\text{det} R \pi_{\mathcal{R}_{ss}} \mathcal{E}(m)) \left( \left( \text{det} \mathcal{E}_x \right)^{\alpha_x} \otimes \bigotimes_{i=1}^{l_x} (\text{det} \mathcal{Q}_x)^{d_i(x)} \right) = \Theta_{\mathcal{R}_{ss}}.$$ 

Thus, by general theorems of GIT, some power of $\Theta_{\mathcal{R}_{ss}}$ descends to an ample line bundle, which implies that some power of $\Theta_{U_{X_0}}$ is ample.

Lemma 1.2. Let $G$ be a reductive algebraic group and $V$ a scheme with $G$-action. Suppose that there exists the good quotient $\pi : V \to V//G$. Then a vector bundle $E$ with $G$-action over $V$ descends to $V//G$ iff stabilizer $\text{stab}(y)$ of $y$ acts on $E_y$ trivially for any $y \in V$ with closed orbit.

It is known that for any torsion free sheaf $F$ of rank $(r_1, r_2)$ on $X_0$ there are integers $a$, $b$, $c$ such that

$$F_{x_0} \cong \mathcal{O}_{X_0, x_0}^a + \mathcal{O}_{X_1, x_0}^b + \mathcal{O}_{X_2, x_0}^c,$$

where $a$, $b$, $c$ are determined uniquely and satisfying

$$r_1 = a + b, \quad r_2 = a + c, \quad \text{dim}(F_{x_0} \otimes k(x_0)) = a + b + c.$$ 

Thus we can define $\pi(E) := a$ for any torsion free sheaf $E$ on $X_0$, and we have
Lemma 1.3. Let $0 \to G \to F \to E \to 0$ be an exact sequence of torsion free sheaves on $X_0$. Then

$$a(F) \geq a(G) + a(E).$$

Proof. It is clear by counting the dimension of their fibres at $x_0$.

Let $R_0 = \{ F \in R \mid F \otimes \mathcal{O}_{x_0} = \mathcal{O}_{x_0} \oplus m_{x_0}^{(r-a)} \}$, and $W_i = R_0 \cup R_1 \cup \cdots \cup R_i$ (which are closed in $R$) endowed with their reduced scheme structures. The subschemes $W_i$ are $SL(n)$-invariant, and yield closed reduced subschemes of $U_X$. It is clear that

$$R \supset W_{r-1} \supset W_{r-2} \supset \cdots \supset W_1 \supset W_0 = R_0,$$

$$U_X \supset W_{r-1} \supset W_{r-2} \supset \cdots \supset W_1 \supset W_0.$$

Let $q_0 \in R$ be a point corresponding to a torsion free sheaf $F_0$ such that

$$F_0 \otimes \mathcal{O}_{X_0,x_0} \cong m_{x_0}^{r-a_0} + \mathcal{O}_{X_0,x_0}.$$

We consider the variety

$$Z = \{(X,Y) \in M(r-a_0) \times M(r-a_0) \mid X \cdot Y = Y \cdot X = 0\},$$

and its subvarieties $Z' = \{(X,Y) \in Z \mid rk(X) + rk(Y) \leq a\}$. Then the reduced coordinate ring of $Z$ is

$$\mathbb{C}[Z] := \frac{\mathbb{C}[X,Y]}{(XY,YX)},$$

where $X := (x_{ij})_{r-a_0 \times r-a_0}$ and $Y := (y_{ij})_{r-a_0 \times r-a_0}$ (see Lemma 4.8 of [Su]), and $Z'$ is a union of reduced subvarieties of $Z$ (see the proof of Theorem 4.2 in [Su]). Thus we can sum up the the arguments of [NS] and [Su] (see also [Fa]) into a lemma

Lemma 1.4. The variety $Z$, $Z'$ is respectively the local model of $R$, $\hat{W}_a$ at the point $q_0$. More precisely, there are some integers $s$ and $t$ such that

$$\mathcal{O}_{R,q_0}(u_1, \cdots, u_s) \cong \mathcal{O}_{Z,(0,0)}([u_1, \cdots, u_t]),$$

$$\mathcal{O}_{\hat{W}_a,q_0}(u_1, \cdots, u_s) \cong \mathcal{O}_{Z',(0,0)}([u_1, \cdots, u_t]).$$

In particular, $W_a$ ($0 \leq a \leq r$) are reduced and seminormal.

§2 Moduli space of generalized parabolic sheaves

Let $\pi : \hat{X}_0 \to X_0$ be the normalisation of $X_0$ and $\pi^{-1}(x_0) = \{x_1, x_2\}$, then $\hat{X}_0$ is a disjoint union of $X_1$ and $X_2$, any coherent sheaf $E$ on $\hat{X}_0$ is determined by a pair $(E_1, E_2)$ of coherent sheaves on $X_1$ and $X_2$. We call as before that $E$ is of rank $(r_1, r_2)$ if $E_i$ has rank $r_i$ on $X_i$ ($i = 1, 2$) and define the rank of $E$ to be

$$r(E) := \frac{c_1 r_1 + c_2 r_2}{c_1 + c_2}.$$
Definition 2.1. A generalized parabolic sheaf of rank \((r_1, r_2)\) (abbreviated to GPS)

\[
E := (E', E_{x_1} \oplus E_{x_2} \leftarrow Q)
\]

on \(\tilde{X}_0\) is a coherent sheaf \(E\) on \(\tilde{X}_0\), torsion free of rank \((r_1, r_2)\) outside \(\{x_1, x_2\}\) with parabolic structures at points \(\{x\}_{x \in I}\), together with a quotient \(E_{x_1} \oplus E_{x_2} \leftarrow Q\). A morphism \(f : (E, E_{x_1} \oplus E_{x_2} \leftarrow Q) \rightarrow (E', E'_{x_1} \oplus E'_{x_2} \leftarrow Q')\) of GPS is a morphism \(f : E \rightarrow E'\) of parabolic sheaves, which maps \(\ker(q)\) into \(\ker(q')\).

We will consider the generalized parabolic sheaves \((E, Q)\) of rank \(r_1 = r_2 = r\) and \(\dim(Q) = r\) with parabolic structures of type \(\{\tilde{\alpha}(x)\}_{x \in I}\) and weights \(\{\tilde{\alpha}(x)\}_{x \in I}\) at the points of \(\pi^{-1}(I)\), and we will call them the GPS of rank \(r\). Furthermore, by a family of GPS of rank \(r\) over \(T\), we mean the following

1. a rank \(r\) sheaf \(\mathcal{E}\) on \(\tilde{X}_0 \times T\) flat over \(T\) and locally free outside \(\{x_1, x_2\} \times T\).
2. a locally free rank \(r\) quotient \(\mathcal{Q}\) of \(\mathcal{E}_{x_1} \oplus \mathcal{E}_{x_2}\) on \(T\).
3. a flag bundle \(Flag_{\tilde{\alpha}(x)}(\mathcal{E}_x)\) on \(T\) with given weights for each \(x \in I\).

Definition 2.2. A GPS \((E, Q)\) is called semistable (resp., stable), if for every nontrivial subsheaf \(E' \subset E\) such that \(E/E'\) is torsion free outside \(\{x_1, x_2\}\), we have, with the induced parabolic structures at points \(\{x\}_{x \in I}\),

\[
\text{par} \chi_m(E') - \dim(Q^{E'}) \leq rk(E') \cdot \frac{\text{par} \chi_m(E) - \dim(Q)}{rk(E)} \quad (\text{resp., <}),
\]

where \(Q^{E'} = q(E'_{x_1} \oplus E'_{x_2}) \subset Q\).

Let \(\chi_1\) and \(\chi_2\) be integers such that \(\chi_1 + \chi_2 - r = \chi\), and fix, for \(i = 1, 2\), the polynomials \(P_i(m) = c_i rm + \chi_i\) and \(W_i = \mathcal{O}_{X_i}(-N)\) where \(\mathcal{O}_{X_i}(1) = \mathcal{O}(1)|_{X_i} = \mathcal{O}_{X_i}(c_i y_i)\). Write \(V_i = \mathbb{C}^{P_i(N)}\) and consider the Quot schemes \(\text{Quot}(V_i \otimes W_i, P_i)\), let \(\bar{\mathcal{Q}}_i\) be the closure of the open set

\[
\mathcal{Q}_i = \left\{ V_i \otimes W_i \rightarrow E_i \rightarrow 0, \text{ with } H^1(E_i(N)) = 0 \text{ and } V \rightarrow H^0(E_i(N)) \text{ induces an isomorphism} \right\},
\]

we have the universal quotient \(V_i \otimes W_i \rightarrow F^i \rightarrow 0\) on \(X_i \times \bar{\mathcal{Q}}_i\) and the relative flag scheme

\[
\mathcal{R}_i = \times_{x \in I_i} Flag_{\tilde{\alpha}(x)}(F^i_x) \rightarrow \bar{\mathcal{Q}}_i.
\]

Let \(\mathcal{E}^i\) be the pullback of \(F^i\) to \(X_i \times \mathcal{R}_i\) and

\[
\rho : \bar{\mathcal{R}} = \text{Grass}_r(\mathcal{E}^1_{x_1} \oplus \mathcal{E}^2_{x_2}) \rightarrow \mathcal{R}_1 \times \mathcal{R}_2.
\]

Then we see that, for \(N\) large enough, every semistable GPS appears as a point of \(\bar{\mathcal{R}}\). To rewrite \(\mathcal{R}_1 \times \mathcal{R}_2\) so that it unified the \(R\) in last section, let \(V = V_1 \oplus V_2\), \(\mathcal{F} = \mathcal{F}^1 \oplus \mathcal{F}^2\) and \(\mathcal{E} = \mathcal{E}^1 \oplus \mathcal{E}^2\), we have

\[
\mathcal{R}_1 \times \mathcal{R}_2 = \times_{\bar{\mathcal{Q}}_1 \times \bar{\mathcal{Q}}_2} Flag_{\tilde{\alpha}(x)}(\mathcal{F}_x) \rightarrow \bar{\mathcal{Q}}_1 \times \bar{\mathcal{Q}}_2.
\]
Note that $V_1 \otimes W_1 \oplus V_2 \otimes W_2 \rightarrow \mathcal{F} \rightarrow 0$ is a $\tilde{Q}_1 \times \tilde{Q}_2$-flat quotient with Hilbert polynomial $P(m) = P_1(m) + P_2(m)$ on $\tilde{X}_0 \times (\tilde{Q}_1 \times \tilde{Q}_2)$, we have for $m$ large enough a $G$-equivariant embedding
\[ \tilde{Q}_1 \times \tilde{Q}_2 \hookrightarrow Grass_{P(m)}(V_1 \otimes W_1^m \oplus V_2 \otimes W_2^m), \]
where $W_i^m = H^0(W_i(m))$ and $G = (GL(V_1) \times GL(V_2)) \cap SL(V)$.

A (closed) point $(p = p_1 \oplus p_2, \{ p_{r(x)}, p_{r_1(x)}, ..., p_{r_l(x)} \}_{x \in I})$ of $\mathcal{R}_1 \times \mathcal{R}_2$ by the expression of (2.1) is given by points $V_i \otimes W_i \xrightarrow{p_i} E^i \rightarrow 0$ of the Quot schemes $(i = 1, 2)$, together with quotients (if we write $\mathcal{V}_{X_0} = V_1 \otimes W_1 \oplus V_2 \otimes W_2$ and $E = E^1 \oplus E^2$)
\[ \{ \mathcal{V}_{X_0} \xrightarrow{p_{r(x)}} Q_{r(x)}, \mathcal{V}_{X_0} \xrightarrow{p_{r_1(x)}} Q_{r_1(x)}, ..., \mathcal{V}_{X_0} \xrightarrow{p_{r_l(x)}} Q_{r_l(x)} \}_{x \in I}, \]
where $r_i(x) = dim(E_x/F_i(E)_x) = n_1(x) + \cdots + n_i(x)$, and $Q_{r(x)} := E_x / Q_{r(x)} := E_x / F_i(E)_x$, the morphisms $p_{r(x)}$ and $p_{r_j(x)} (j = 1, ..., l_x)$ are defined to be
\[ p_{r(x)} : \mathcal{V}_{X_0} \xrightarrow{p} E \rightarrow E_x, \quad p_{r_j(x)} : \mathcal{V}_{X_0} \xrightarrow{p_{r(x)}} Q_{r(x)} = E_x \rightarrow E_x / F_j(E)_x. \]
Thus we have a $G$-equivariant embedding
\[ \mathcal{R}_1 \times \mathcal{R}_2 \hookrightarrow Grass_{P(m)}(V_1 \otimes W_1^m \oplus V_2 \otimes W_2^m) \times \text{Flag}, \]
where $\text{Flag}$ is defined to be
\[ \text{Flag} = \prod_{x \in I} \{ Grass_{r(x)}(V) \times Grass_{r_1(x)}(V) \times \cdots \times Grass_{r_l(x)}(V) \}, \]
which maps a point $(p = p_1 \oplus p_2, \{ p_{r(x)}, p_{r_1(x)}, ..., p_{r_l(x)} \}_{x \in I})$ of $\mathcal{R}_1 \times \mathcal{R}_2$ to the point
\[ (H^0(\mathcal{V}_{X_0}(m))) \xrightarrow{g} U, \{ V \xrightarrow{g_{r(x)}} U_{r(x)}, V \xrightarrow{g_{r_1(x)}} U_{r_1(x)}, ..., V \xrightarrow{g_{r_l(x)}} U_{r_l(x)} \}_{x \in I}, \]
of $\text{Grass}_{P(m)}(V_1 \otimes W_1^m \oplus V_2 \otimes W_2^m) \times \text{Flag}$, where $g := H^0(p(m)), U := H^0(E(m)), g_{r(x)} := H^0(p_{r(x)}(N)), U_{r(x)} := H^0(Q_{r(x)}), g_{r_j(x)} := H^0(p_{r_j(x)}(N)), U_{r_j(x)} := H^0(Q_{r_j(x)}) (j = 1, ..., l_x)$. Finally, we get a $G$-equivariant embedding
\[ \tilde{\mathcal{R}} \hookrightarrow G' = \text{Grass}_{P(m)}(V_1 \otimes W_1^m \oplus V_2 \otimes W_2^m) \times \text{Flag} \times \text{Grass}_r(V_1 \oplus V_2) \]
as follows: a point of $\tilde{\mathcal{R}}$ is given by a point of $\mathcal{R}_1 \times \mathcal{R}_2$ together with a quotient $E_{x_1} \oplus E_{x_2} \xrightarrow{q} Q$, then above embedding maps $E_{x_1} \oplus E_{x_2} \xrightarrow{q} Q$ to
\[ g_G := H^0(q(N)) : V_1 \oplus V_2 = H^0(\mathcal{V}_{X_0}(N)) \rightarrow H^0(E(N)) \rightarrow E_{x_1} \oplus E_{x_2} \xrightarrow{q} Q. \]
Given $G'$ the polarisation (using the obvious notation):
\[ \left\{ \frac{\ell}{m - N} \times \prod_{x \in I} \{ \alpha_x, d_1(x), \cdots, d_{l_x}(x) \} \right\} \times k, \]
we have the analogue of Proposition 1.1, whose proof (we refer to Proposition 1.14 of [B3], or Lemma 5.4 of [NS]) is a modification of Theorem 4.17 in [Ne] since our group $G$ here is different from that of [Ne].
**Proposition 2.1.** A point \((g, \{g_r(x), g_{r_1}(x), ..., g_{r_{i}}(x)\}_{x \in I}, g_G) \in G'\) is stable (respectively, semistable) for the action of \(G\), with respect to the above polarisation (we refer to this from now on as GIT-stability), if and only if for all nontrivial subspaces \(H \subset V\), where \(H = H_1 \oplus H_2\) and \(H_i \subset V_i\) \((i = 1, 2)\), we have (with \(h = \dim H\) and \(\bar{H} := H_1 \otimes W_1^m + H_2 \otimes W_2^m\))

\[
\frac{\ell}{m - N} (hP(m) - P(N)\dim g(\bar{H})) + \sum_{x \in I} \alpha_x (rh - P(N)\dim g_{r(x)}(H)) + \sum_{x \in I} \sum_{i=1}^{l_x} d_i(x) (r_i(x)h - P(N)\dim g_{r_i(x)}(H)) + k(rh - P(N)\dim g_{G}(H)) < (\leq) 0.
\]

**Proposition 2.2.** Suppose \((p, \{p_r(x), p_{r_1}(x), ..., p_{r_{i}}(x)\}_{x \in I}, q) \in \tilde{R}\) is a point such that \(E\) is torsion free outside \(\{x_1, x_2\}\). Then \(E = (E, E_{x_1} \oplus E_{x_2} \xrightarrow{q} Q)\) is stable (respectively, semistable) iff for every subsheaf \(0 \neq F \neq E\) we have (using the notation 1.2)

\[
\frac{\ell}{m - N} (\chi(F(N))P(m) - P(N)\chi(F(m))) + \sum_{x \in I} \alpha_x (r\chi(F(N)) - P(N)h^0(Q^F_{r(x)}))
\]

\[
+ \sum_{x \in I} \sum_{i=1}^{l_x} d_i(x)(r_i(x)\chi(F(N)) - P(N)h^0(Q^F_{r_i(x)}))
\]

\[
+ k(r\chi(F(N)) - P(N)\dim(Q^F)) < (\leq) 0.
\]

**Proof.** For subsheaf \(F \subset E\) such that \(E/F\) is torsion free outside \(\{x_1, x_2\}\), by the same computation in Proposition 1.2, we have

\[
LHS(F) = kP(N) \left( \frac{\text{par } \chi_m(F) - \dim(Q^F)}{r(F)} - r(F) \frac{\text{par } \chi_m(E) - r}{r} \right).
\]

Thus \(E\) is stable (semistable) iff \(LHS(F) < (\leq) 0\) for the required \(F\). If \(E/F\) has torsion outside \(\{x_1, x_2\}\), then \(LHS(F) < 0\).

**Lemma 2.1.** There exist \(N\) and \(M_1(N)\) such that for \(m \geq M_1(N)\) the following holds. Suppose \((p, \{p_r(x), p_{r_1}(x), ..., p_{r_{i}}(x)\}_{x \in I}, q) \in \tilde{R}\) is a point which is GIT-semistable then for all quotients \(E \xrightarrow{T} G \rightarrow 0\) we have (with \(Q^G := Q/q(\ker(T))\))

\[
h^0(G(N)) \geq \frac{1}{k} \left( (c_1 + c_2)r(G)\ell + \sum_{x \in I} \alpha_x h^0(Q^G_{r(x)}) + \sum_{x \in I} \sum_{i=1}^{l_x} d_i(x)h^0(Q^G_{r_i(x)}) \right) + h^0(Q^G).
\]

In particular, \(E\) is torsion free outside \(\{x_1, x_2\}\), \(q\) maps the torsion on \(\{x_1, x_2\}\) to \(Q\) injectively and \(V \rightarrow H^0(E(N))\) is an isomorphism.

**Proof.** The proof of Lemma 1.1 goes through with obvious modifications except that we can not assume that the sheaves \(E\) are torsion free at \(x_1\) and \(x_2\). To see it clearly, we write out the proof of \(E\) being torsion free outside \(\{x_1, x_2\}\).
Let $\tau = Tor(E)$, $\mathcal{G} = E/\tau$ and applying the above inequality, noting that $h^0(\mathcal{G}(N)) = P(N) - h^0(\tau)$, $h^0(Q^\tau_{r(x)}) = r - h^0(Q^\tau_{r(x)})$ and $h^0(Q^\tau_{r_i(x)}) = r_i(x) - h^0(Q^\tau_{r_i(x)})$, we have

$$k h^0(\tau) \leq k \cdot \text{dim}(Q^\tau) + \sum_{x \in I} (\alpha_x + a_{l_x+1}(x) - a_1(x)) h^0(\tau_x),$$

by which one can conclude that $\tau = 0$ outside $\{x_1, x_2\}$ and $h^0(\tau_{x_1} \oplus \tau_{x_2}) - \text{dim}(Q^\tau) = 0$ since $\alpha_x < k - a_{l_x+1}(x) + a_1(x)$. In particular, $q$ maps the torsion on $\{x_1, x_2\}$ to $Q$ injectively.

**Remark 2.1.** The proof of Lemma 1.1 and Lemma 2.1 actually implies that one can take $N$ big enough such that for a GIT-semistable point the sheaf $E$ involved satisfies the condition $H^1(E(N)((-x - x_1 - x_2))) = 0$ for any $x \in X_0$, which implies that $E(N)$ and $E(N)((-x_1 - x_2)$ are generated by global sections and $H^0(E(N)) \to E(N)_{x_1} \oplus E(N)_{x_2}$ is surjective. Conversely, it is easy to prove that every semistable GPS will satisfy above conditions if $N$ big enough.

**Proposition 2.3.** There exist integers $N > 0$ and $M(N) > 0$ such that for $m \geq M(N)$ the following is true. A point $(p, \{p_{r(x)}, p_{r_1(x)}, \ldots, p_{r_j(x)}\} x \in I, q) \in \tilde{R}$ is GIT-stable (respectively, GIT-semistable) if the quotient $E$ is torsion free outside $\{x_1, x_2\}$ and $E = (E, q)$ is stable (respectively, semistable) GPS, the map $V \to H^0(E(N))$ is an isomorphism.

**Proof.** The proof is the same with that of Proposition 1.3 by some obvious notation modifications.

**Notation 2.1.** Define $\mathcal{H}$ to be the subscheme of $\tilde{R}$ parametrising the generalised parabolic sheaves $E = (E, E_{x_1} \oplus E_{x_2} \xrightarrow{q} Q)$ satisfying

1. $C^0(N) \cong H^0(E(N))$, and $H^1(E(N)((-x_1 - x_2)) = 0$ for any $x \in \tilde{X}_0$
2. Tor$E$ is supported on $\{x_1, x_2\}$ and Tor$E_{x_1} \oplus$ Tor$E_{x_2}$ $\hookrightarrow Q$.

Let $\tilde{R}^{ss}$ ($\tilde{R}^s$) be the open set of $\tilde{R}$ consists the semistable (stable) GPS, then it is clear that

$$\tilde{R}^{ss} \open \subset \mathcal{H} \open \subset \tilde{R}.$$ 

We will introduce the so called s-equivalence of GPS later in Definition 2.6. It is also known that $\mathcal{H}$ is reduced, normal and Gorenstein with only rational singularities (see Proposition 3.2 and Remark 3.1 in [Su]).

**Theorem 2.1.** For given datas in Notation 1.1 satisfying $(*)$ and $\chi_1, \chi_2$ with $\chi_1 + \chi_2 - r = \chi$, there exists an irreducible, Gorenstein, normal projective variety $\mathcal{P}_{\chi_1, \chi_2}$ with only rational singularities, which is the coarse moduli space of s-equivalence classes of semistable GPS $(E, Q)$ on $\tilde{X}_0$ of rank $r$ and $\chi(E_j) = \chi_j$ ($j = 1, 2$) with parabolic structures of type $\{\bar{a}(x)\}_{x \in I}$ and weights $\{\bar{a}(x)\}_{x \in I}$ at points $\{x\}_{x \in I}$.

**Proof.** The existence of the moduli space and its projectivity follows above Proposition 2.3 and G.I.T., the other properties follow the corresponding properties of $\mathcal{H}$ and the fact that $\tilde{R}^{ss} \subset \mathcal{H}$ for if $N$ big enough.

Recall that we have the universal quotient $\mathcal{E}^1$ on $X_1 \times \mathcal{R}_1$, flat over $\mathcal{R}_1$, and torsion free of rank $r$ outside $\{x_1\}$ with Euler characteristic $\chi_1$, together with, for
Lemma 2.2. The proof is similar with Theorem 1.2, we only make a remark here. If $\rho^*(\Theta_{R_1} \otimes \Theta_{R_2}) \otimes (\text{det} Q)^k$

Similarly, we can define the line bundle $\Theta_{R_2}$ on $R_2$ and the $G$-line bundle $\Theta_{\tilde{R}} := \rho^*(\Theta_{R_1} \otimes \Theta_{R_2}) \otimes (\text{det} Q)^k$

on $\tilde{R}$, where $\rho^*(\Theta_{x_1} \oplus \Theta_{x_2}) \rightarrow Q \rightarrow 0$ is the universal quotient on $\tilde{R}$. One can check that $\Theta_{\tilde{R}}$ is the restriction of ample polarisation used to linearize the action of $G$, thus some power of $\Theta_{\tilde{R}}$ descends to an ample line bundle on $\mathcal{P}_{x_1,x_2}$. In fact, we have

**Lemma 2.2.** The $\Theta_{\tilde{R}_{x_2}}$ descends to an ample line bundle $\Theta_{\mathcal{P}_{x_1,x_2}}$ on $\mathcal{P}_{x_1,x_2}$.

**Proof.** The proof is similar with Theorem 1.2, we only make a remark here. If $(E, Q)$ is a semistable GPS of rank $r$ and $(E', Q')$ a sub-GPS of $(E, Q)$ with

$$\text{par}_m(E') - \dim(Q') = r(E') \cdot \frac{\text{par}_m(E) - \dim(Q)}{r},$$

we have (assuming that $E'$ is of rank $(r_1, r_2)$)

$$-k \chi(E') + r_1 \sum_{x \in I_1} \alpha_x + r_2 \sum_{x \in I_2} \alpha_x + \sum_{x \in I} \sum_{i=1}^{l_x} d_i(x) \frac{E_x'}{E_x \cap F_i(E_x)} + r_1 \ell_1 + r_2 \ell_2 + k \cdot \dim(Q')$$

$$= \frac{-k \chi + \sum_{x \in I} \alpha_x + \sum_{x \in I} \sum_{i=1}^{l_x} d_i(x) r_i(x) + r(\ell_1 + \ell_2)}{r} \cdot r(E') = 0.$$

**Notation 2.2.** Let $R_{1,F} \subset R_1$ ($R_{2,F} \subset R_2$) be the open set of points corresponding to the vector bundles on $X_1$ ($X_2$), and $\tilde{R}_F = \rho^{-1}(R_{1,F} \times R_{2,F})$, then

$$\rho : \tilde{R}_F \rightarrow R_{1,F} \times R_{2,F}$$

is a grassmannian bundle over $R_{1,F} \times R_{2,F}$, and $\tilde{R}_F \subset \mathcal{H}$. We define

$$R^1_{F,a} := \{(E, Q) \in \tilde{R}_F | E_a \rightarrow Q \text{ has rank } a\},$$

and $\tilde{D}_{F,1}(i) := R^1_{F,0} \cup \cdots \cup R^1_{F,i}$, which have the natural scheme structures. The subschemes $R^2_{F,a}$ and $\tilde{D}_F,2(i)$ are defined similarly. Let $\tilde{D}_1(i)$ and $\tilde{D}_2(i)$ be the zariski closure of $\tilde{D}_{F,1}(i)$ and $\tilde{D}_{F,2}(i)$ in $\tilde{R}$. Then they are reduced, irreducible and $G$-invariant closed subschemes of $\tilde{R}$, thus inducing closed subschemes $\mathcal{D}_1(i)_{x_1,x_2}$, $\mathcal{D}_2(i)_{x_1,x_2}$ of $\mathcal{P}_{x_1,x_2}$. Clearly, we have (for $j = 1, 2$) that

$$\tilde{R} \supset \tilde{D}_j(r - 1) \supset \tilde{D}_j(r - 2) \cdots \supset \tilde{D}_j(1) \supset \tilde{D}_j(0)$$

and $\mathcal{P}_{x_1,x_2} \supset \mathcal{D}_j(r - 1)_{x_1,x_2} \supset \mathcal{D}_j(r - 2)_{x_1,x_2} \supset \cdots \supset \mathcal{D}_j(1)_{x_1,x_2} \supset \mathcal{D}_j(0)_{x_1,x_2}$. 

---

Notation 2.2. Let $R_{1,F} \subset R_1$ ($R_{2,F} \subset R_2$) be the open set of points corresponding to the vector bundles on $X_1$ ($X_2$), and $\tilde{R}_F = \rho^{-1}(R_{1,F} \times R_{2,F})$, then

$$\rho : \tilde{R}_F \rightarrow R_{1,F} \times R_{2,F}$$

is a grassmannian bundle over $R_{1,F} \times R_{2,F}$, and $\tilde{R}_F \subset \mathcal{H}$. We define

$$R^1_{F,a} := \{(E, Q) \in \tilde{R}_F | E_a \rightarrow Q \text{ has rank } a\},$$

and $\tilde{D}_{F,1}(i) := R^1_{F,0} \cup \cdots \cup R^1_{F,i}$, which have the natural scheme structures. The subschemes $R^2_{F,a}$ and $\tilde{D}_F,2(i)$ are defined similarly. Let $\tilde{D}_1(i)$ and $\tilde{D}_2(i)$ be the zariski closure of $\tilde{D}_{F,1}(i)$ and $\tilde{D}_{F,2}(i)$ in $\tilde{R}$. Then they are reduced, irreducible and $G$-invariant closed subschemes of $\tilde{R}$, thus inducing closed subschemes $\mathcal{D}_1(i)_{x_1,x_2}$, $\mathcal{D}_2(i)_{x_1,x_2}$ of $\mathcal{P}_{x_1,x_2}$. Clearly, we have (for $j = 1, 2$) that

$$\tilde{R} \supset \tilde{D}_j(r - 1) \supset \tilde{D}_j(r - 2) \cdots \supset \tilde{D}_j(1) \supset \tilde{D}_j(0)$$

and $\mathcal{P}_{x_1,x_2} \supset \mathcal{D}_j(r - 1)_{x_1,x_2} \supset \mathcal{D}_j(r - 2)_{x_1,x_2} \supset \cdots \supset \mathcal{D}_j(1)_{x_1,x_2} \supset \mathcal{D}_j(0)_{x_1,x_2}$.
Lemma 2.3. \( \mathcal{H}, \mathcal{D}_j(a) \) and \( \mathcal{D}_1(a) \cap \mathcal{D}_2(b) \) are reduced, normal with rational singularities. In particular, \( \mathcal{P}_{\chi_1, \chi_2}, \mathcal{D}_j(a)_{\chi_1, \chi_2} \) and \( \mathcal{D}_1(a)_{\chi_1, \chi_2} \cap \mathcal{D}_2(b)_{\chi_1, \chi_2} \) are reduced, normal with rational singularities.

Proof. This is the copy of Proposition 3.2 in [Su] and the proof there goes through.

Let \( (E, Q) \) be a semistable GPS of rank \( r \) with \( E = (E_1, E_2) \) and \( \chi_j = \chi(E_j) \) \( (j = 1, 2) \). Then, by the definition of semistability, we have (for \( j = 1, 2 \)) that

\[
\text{par}_m(E_j) - \dim(Q^{E_j}) \leq \frac{c_j}{c_1 + c_2}(\text{par}_m(E) - r).
\]

Recall that \( \chi_1 + \chi_2 - r = \chi \) and \( n_j \) \( (j = 1, 2) \) denotes

\[
\frac{1}{k} \left( \sum_{x \in I_j} \sum_{i=1}^{l_x} d_i(x)r_i(x) + r \sum_{x \in I_j} \alpha_x + r\ell_j \right),
\]
we can rewrite the above inequality into

\[
(2.1) \quad n_1 + r - \dim(Q^{E_2}) \leq \chi(E_1) \leq n_1 + \dim(Q^{E_1})
\]
\[
\quad n_2 + r - \dim(Q^{E_1}) \leq \chi(E_2) \leq n_2 + \dim(Q^{E_2}).
\]

Thus, for fixed \( \chi \), the moduli space of \( s \)-equivalence classes of semistable GPS \( (E, Q) \) on \( \hat{X}_0 \) of rank \( r \) and \( \chi(E) = \chi + r \) with parabolic structures of type \( \{\hat{n}(x)\}_{x \in I} \) and weights \( \{\hat{a}(x)\}_{x \in I} \) at points \( \{x\}_{x \in I} \) is the disjoint union

\[
\mathcal{P} := \coprod_{\chi_1 + \chi_2 = \chi + r} \mathcal{P}_{\chi_1, \chi_2},
\]
where \( \chi_1, \chi_2 \) satisfy the inequalities

\[
(2.2) \quad n_1 \leq \chi(E_1) \leq n_1 + r, \quad n_2 \leq \chi(E_2) \leq n_2 + r.
\]

Notation 2.3. The ample line bundles \( \{\Theta_{\mathcal{P}_{\chi_1, \chi_2}}\} \) determine an ample line bundle \( \Theta_{\mathcal{P}} \) on \( \mathcal{P} \), and for any \( 0 \leq a \leq r \), we define the subschemes

\[
\mathcal{D}_1(a) := \coprod_{\chi_1 + \chi_2 = \chi + r} \mathcal{D}_1(a)_{\chi_1, \chi_2}, \quad \mathcal{D}_2(a) := \coprod_{\chi_1 + \chi_2 = \chi + r} \mathcal{D}_2(a)_{\chi_1, \chi_2}.
\]

We will simply write \( \mathcal{D}_1 := \mathcal{D}_1(r - 1) \) and \( \mathcal{D}_2 := \mathcal{D}_2(r - 1) \).

In order to introduce a sheaf theoretic description of the so called \( s \)-equivalence of GPS, we enlarge the category by considering all of the GPS including the case \( r(E) = 0 \), and also assume that \( |I| = 0 \) for simplicity.

Definition 2.3. A GPS \( (E, Q) \) is called semistable (resp., stable), if

1. when \( \text{rank}(E) > 0 \), then for every nontrivial subsheaf \( E' \subset E \) such that \( E/E' \) is torsion free outside \( \{x_1, x_2\} \), we have, with the induced parabolic structures at points \( \{x\}_{x \in I} \),

\[
\text{par}_m(E') - \dim(Q^{E'}) \leq rk(E') \cdot \frac{\text{par}_m(E) - \dim(Q)}{rk(E)} \quad (\text{resp.,} <),
\]

where \( Q^{E'} = q(E'_{x_1} \oplus E'_{x_2}) \subset Q \).

2. when \( \text{rank}(E) = 0 \), then \( E_{x_1} \oplus E_{x_2} = Q \) (resp. \( E_{x_1} \oplus E_{x_2} = Q \) and \( \dim(Q) = 1 \)).
Definition 2.4. If $(E, Q)$ is a GPS and $\text{rank}(E) > 0$, we set

$$\mu_G[(E, Q)] = \frac{\text{deg}(E) - \text{dim}(Q)}{\text{rank}(E)}.$$ 

It is useful to think of an $m$-GPS as a sheaf $E$ on $\tilde{X}_0$ together with a map $\pi_*E \to x_0Q \to 0$ and $h^0(x_0Q) = m$. Let $K_E$ denote the kernel of $\pi_*E \to Q \to 0$.

Definition 2.5. Given an exact sequence

$$0 \to E' \to E \to E'' \to 0$$

of sheaves on $\tilde{X}$, and $\pi_*E \to Q \to 0$ a generalised parabolic structure on $E$, we define the generalised parabolic structures on $E'$ and $E''$ via the diagram

$$
\begin{array}{cccccc}
0 & \longrightarrow & \pi_*E' & \longrightarrow & \pi_*E & \longrightarrow & \pi_*E'' & \longrightarrow & 0 \\
& & \downarrow & & \downarrow & & \downarrow & & \\
0 & \longrightarrow & Q' & \longrightarrow & Q & \longrightarrow & Q'' & \longrightarrow & 0
\end{array}
$$

The first horizontal sequence is exact because $\pi$ is finite, $Q'$ is defined as the image in $Q$ of $\pi_*E'$ so that the first vertical arrow is onto, $Q''$ is defined by demanding that the second horizontal sequence is exact, and finally the third vertical arrow is onto by the snake lemma. We will write

$$0 \to (E', Q') \to (E, Q) \to (E'', Q'') \to 0$$

whose meaning is clear.

Proposition 2.4. Fix a rational number $\mu$. Then the category $\mathcal{C}_\mu$ of semistable GPS $(E, Q)$ such that $\text{rank}(E) = 0$ or, $\text{rank}(E) > 0$ with $\mu_G[(E, Q)] = \mu$, is an abelian, artinian, noetherian category whose simple objects are the stable GPS in the category.

One can conclude, as usual, that given a semistable GPS $(E, Q)$ it has a Jordan-Hölder filtration, and the associated graded GPS $\text{gr}(E, Q)$ is uniquely determined by $(E, Q)$. Thus we have

Definition 2.6. Two semistable GPS $(E_1, Q_1)$ and $(E_2, Q_2)$ are said to be $s$-equivalent if they have the same associated graded GPS, namely,

$$(E_1, Q_1) \sim (E_2, Q_2) \iff \text{gr}(E_1, Q_1) \cong \text{gr}(E_2, Q_2).$$

Remark 2.2. Any stable GPS $(E, Q)$ with $\text{rank}(E) > 0$ must be locally free (i.e., $E$ is locally free), and two stable GPS are $s$-equivalent iff they are isomorphic.

Proposition 2.5. Every semistable $(E', Q')$ with $\text{rank}(E') > 0$ is $s$-equivalent to a semistable $(E, Q)$ with $E$ locally free. Moreover,

(1) if $E'$ has torsion of dimension $t$ at $x_2$, then $(E', Q')$ is $s$-equivalent to a semistable $(E, Q)$ with $E$ locally free and

$$\text{rank}(E, Q) < \text{dim}(Q) - t$$

and

(2) if $(E', Q')$ has a semistable lift $(E, Q)$ with $E$ locally free and $\pi_*E \to Q \to 0$ is injective, then $(E', Q')$ is $s$-equivalent to a stable $(E, Q)$ with $E$ locally free.
(2) if \((E, Q)\) is a semistable GPS with \(E\) locally free and
\[
\text{rank}(E_{x_1} \to Q) = a,
\]
then \((E, Q)\) is \(s\)-equivalent to a semistable \((E', Q')\) such that
\[
\dim(\text{Tor}(E')_{x_2}) = \dim(Q) - a.
\]

The roles of \(x_1, x_2\) in the above statements can be reversed.

Proof. We prove (1) at first. For given \((E', Q') \in C_\mu\) with \(\text{rank}(E') > 0\), there is an exact sequence
\[
0 \to (E'_1, Q'_1) \to (E', Q') \to (E'_2, Q'_2) \to 0
\]
such that \((E'_2, Q'_2)\) is stable and \(\mu_C[(E'_2, Q'_2)] = \mu\) if \(\text{rank}(E'_2) > 0\). It is clear that
\[
\text{gr}(E', Q') = \text{gr}(E'_1, Q'_1) \oplus (E'_2, Q'_2).
\]

When \(\text{rank}(E'_2) > 0\), the \(E'_2\) has to be locally free and \(E'_1\) has the same torsion with \(E'\). Thus if \(\text{rank}(E'_1) > 0\), there is (by using induction for the rank) a \((E_1, Q_1) \in C_\mu\) with \(E_1\) locally free and
\[
\text{rank}(E_{x_1} \to Q_1) \leq \dim(Q_1) - t
\]
such that \(\text{gr}(E_1, Q_1) = \text{gr}(E'_1, Q'_1)\). One can check that
\[
(E, Q) := (E_1 \oplus E'_2, Q_1 \oplus Q'_2) \in C_\mu
\]
is \(s\)-equivalent to \((E', Q')\) and
\[
\text{rank}(E_{x_1} \to Q) \leq \dim(Q) - t.
\]
If \(\text{rank}(E'_1) = 0\), then \(\text{gr}(E', Q') = (E'_2, Q'_2) \oplus \text{gr}(\text{Tor}(E'), \text{Tor}(E'))\). Thus \((E', Q')\) satisfies (up to a \(s\)-equivalence) the exact sequence
\[
0 \to (\tilde{E}', \tilde{Q}') \to (E', Q') \to (x_2 \mathbb{C}, \mathbb{C}) \to 0,
\]
where \((\tilde{E}', \tilde{Q}') \in C_\mu\) has torsion of dimension \(t - 1\) at \(x_2\). This is the typical case we treated in Lemma 2.5 of [Su], and we will indicate later how to get our stronger statement by the construction of [Su].

When \(\text{rank}(E'_2) = 0\) and \(\dim(\text{Tor}(E'_1)_{x_2}) < t\), then \((E'_2, Q'_2)\) has to be \((x_2 \mathbb{C}, \mathbb{C})\), which is again the above typical case we will treat. If \(\dim(\text{Tor}(E'_1)_{x_2}) = t\), by repeating the above procedures for \((E'_1, Q'_1)\), we will reduce the proof, after finite steps, to the above cases again since \(\dim(Q'_1)\) decreases strictly. All in all, we are reduced to treating the typical case:
\[
0 \to (\tilde{E}', \tilde{Q}') \to (E', Q') \to (x_2 \mathbb{C}, \mathbb{C}) \to 0,
\]
where \((\tilde{E}', \tilde{Q}') \in C_\mu\) and \(\dim(\text{Tor}(\tilde{E}')_{x_2}) = t - 1\).
By using the induction for $t$, there exists a $(\tilde{E}, \tilde{Q}) \in C_\mu$ with $\tilde{E}$ locally free such that $gr(\tilde{E}, \tilde{Q}) = gr(\tilde{E}', \tilde{Q}')$ and

$$rank(\tilde{q}_1 : \tilde{E}_x \to \tilde{Q}) \leq dim(\tilde{Q}) - (t - 1),$$

where $\tilde{q}_1, \tilde{q}_2$ are the induced maps by $\tilde{q} : \tilde{E}_x \oplus \tilde{E}_x \to \tilde{Q}$. Since $(x_2C, \mathbb{C})$ is stable, we have

$$gr(E', Q') = gr(\tilde{E}, \tilde{Q}) \oplus (x_2C, \mathbb{C}).$$

Let $K_2 = ker(\tilde{q}_1 : \tilde{E}_x \to \tilde{Q})$, choosing a Hecke modification $h : \tilde{E} \to E$ at $x_2$ (see Remark 1.4 of [NS]) such that $\tilde{K}_2 := ker(h_{x_2}) \subset K_2$ and $dim(\tilde{K}_2) = 1$, we get the extension

$$0 \to \tilde{E} \xrightarrow{h} E \xrightarrow{\gamma} x_2C \to 0.$$

Let $Q = Q \oplus \mathbb{C}$ and $E_{x_2} = h_{x_2}(\tilde{E}_{x_2}) \oplus V_1$ for a subspace $V_1$, we define a morphism $f : E_{x_1} \oplus E_{x_2} \to Q$ such that $E_{x_1} \to Q$ to be

$$E_{x_1} \xrightarrow{h_{x_1}^{-1}} \tilde{E}_{x_1} \xrightarrow{\tilde{q}_1} \tilde{Q} \hookrightarrow Q$$

and $E_{x_2} \to Q$ to be

$$E_{x_2} = h_{x_2}(\tilde{E}_{x_2}) \oplus V_1 \xrightarrow{\tilde{h}_{x_2}, \gamma_{x_2}} \tilde{E}_{x_2} \oplus \mathbb{C} \xrightarrow{(\tilde{q}_2, id)} \tilde{Q} \oplus \mathbb{C} = Q$$

where $\tilde{h}_{x_2} : \tilde{E}_{x_2}/\tilde{K}_2 \cong h_{x_2}(\tilde{E}_{x_2})$ and $\tilde{q}_2 : \tilde{E}_{x_2}/\tilde{K}_2 \to \tilde{Q}$ (note that $\tilde{K}_2 \subset K_2$). Thus the following diagram is commutative

$$\begin{array}{ccc}
E_{x_1} \oplus \tilde{E}_{x_2} & \xrightarrow{(h_{x_1}, h_{x_2})} & E_{x_1} \oplus E_{x_2} \xrightarrow{(0, \gamma_{x_2})} \mathbb{C} \xrightarrow{f} 0 \\
q \downarrow & & \downarrow f \\
0 & \longrightarrow & \tilde{Q} \oplus \mathbb{C} \longrightarrow \mathbb{C} \longrightarrow 0
\end{array}$$

One checks that $f$ is surjective by this diagram, and thus

$$0 \to (\tilde{E}, \tilde{Q}) \to (E, Q) \to (x_2C, \mathbb{C}) \to 0.$$

It is easy to see that $(E, Q) \in C_\mu$ is s-equivalent to $(E', Q')$ and

$$rank(E_{x_1} \to Q) = rank(\tilde{E}_{x_1} \to \tilde{Q}) \leq dim(\tilde{Q}) - t.$$
Lemma 2.4. Given a \((E, Q) \in \mathcal{C}_\mu\), if there is an exact sequence
\[
0 \to (E_1, Q_1) \to (E, Q) \to (E_2, Q_2) \to 0
\]
such that \((E_2, Q_2) \in \mathcal{C}_\mu\), then
\[
gr(E, Q) = gr(E_1, Q_1) \oplus gr(E_2, Q_2).
\]
In particular, \((E, Q)\) is s-equivalent to \((E_1 \oplus E_2, Q_1 \oplus Q_2)\).

Proof. Since \((E_2, Q_2) \in \mathcal{C}_\mu\), there exists an exact sequence
\[
0 \to (E'_2, Q'_2) \to (E_2, Q_2) \to (E''_2, Q''_2) \to 0
\]
such that \((E'_2, Q'_2) \in \mathcal{C}_\mu\) is stable. Thus
\[
gr(E_2, Q_2) = gr(E'_2, Q'_2) \oplus (E''_2, Q''_2).
\]

On the other hand, if we define \((\tilde{E}, \tilde{Q})\) by exact sequence
\[
0 \to (\tilde{E}, \tilde{Q}) \to (E, Q) \xrightarrow{\delta} (E''_2, Q''_2) \to 0,
\]
where \(g : (E, Q) \to (E_2, Q_2) \to (E''_2, Q''_2)\), then we have an exact sequence
\[
0 \to (E_1, Q_1) \to (\tilde{E}, \tilde{Q}) \to (E'_2, Q'_2) \to 0,
\]
and \((E'_2, Q'_2) \in \mathcal{C}_\mu\). By using the induction for the \(\text{rank}(E_2)\) and \(h^0(E_2)\) when \(\text{rank}(E_2) = 0\), we have
\[
gr(\tilde{E}, \tilde{Q}) = gr(E_1, Q_1) \oplus gr(E'_2, Q'_2).
\]
Now the lemma is clear.

§3 The factorization theorem

Recall that \(\pi : \tilde{X}_0 \to X_0\) is the normalisation of \(X_0\) and \(\pi^{-1}(x_0) = \{x_1, x_2\}\).

Given a GPS \((E, E_{x_1} \oplus E_{x_2} \xrightarrow{q} Q)\) on \(\tilde{X}_0\), we define a coherent sheaf \(\phi(E, Q) := F\) by the exact sequence
\[
0 \to F \to \pi^*(E) \to x_0 Q \to 0,
\]
where we use \(x W\) to denote the skyscraper sheaf supported at \(\{x\}\) with fibre \(W\), and the morphism \(\pi^*(E) \to x_0 Q\) is defined as follows
\[
\pi^*(E) \to \pi^*(E)|_{\{x_0\}} = x_0 (E_{x_1} \oplus E_{x_2}) \xrightarrow{q} x_0 Q.
\]
It is clear that \(F\) is torsion free of rank \((r_1, r_2)\) if and only if \((E, Q)\) is a GPS of rank \((r_1, r_2)\) and satisfying
\[
(T) \quad (\text{Tor}E)_{x_1} \oplus (\text{Tor}E)_{x_2} \xrightarrow{q} Q.
\]
In particular, the GPS in \(\mathcal{H}\) give in this way torsion free sheaves of rank \(r\) with the natural parabolic structures at points of \(I\).
Lemma 3.1. Let $(E, Q)$ satisfy condition $(T)$, and $F = \phi(E, Q)$ the associated torsion free sheaf on $X_0$. We have

1. If $E$ is a vector bundle and the maps $E_{x_1} \to Q$ are isomorphisms, then $F$ is a vector bundle.
2. If $F$ is a vector bundle on $X_0$, then there is an unique $(E, Q)$ such that $\phi(E, Q) = F$. In fact, $E = \pi^*F$.
3. If $F$ is a torsion free sheaf, then there is a $(E, Q)$, with $E$ a vector bundle on $\tilde{X}_0$, such that $\phi(E, Q) = F$ and $E_{x_2} \to Q$ is an isomorphism. The rank of the map $E_{x_1} \to Q$ is a iff $F \otimes \hat{O}_{x_0} \cong \hat{O}_{x_0} \oplus m_{x_0}^{\oplus(r-a)}$. The roles of $x_1$ and $x_2$ can be reversed.
4. Every torsion free rank $r$ sheaf $F$ on $X_0$ comes from a $(E, Q)$ such that $E$ is a vector bundle.

Proof. Similar with Lemma 4.6 of [NR] and Lemma 2.1 of [Su].

Lemma 3.2. Let $F = \phi(E, Q)$, then $F$ is semistable if and only if $(E, Q)$ is semistable. Moreover, one has

1. If $(E, Q)$ is stable, then $F$ is stable.
2. If $F$ is a stable vector bundle, then $(E, Q)$ is stable.

Proof. For any subsheaf $E' \subset E$ such that $E/E'$ is torsion free outside $\{x_1, x_2\}$, the induced GPS $(E', Q^{E'})$ defines a subsheaf $F' \subset F$ by

$$0 \to F' \to \pi_*(E') \to x_0Q^{E'} \to 0.$$ 

It is clear that $\text{par}_m(F') = \text{par}_m(E') - \text{dim}(Q^{E'})$, thus $F$ semistable implies $(E, Q)$ semistable. Note that $E$ may have torsion and thus $(E, Q)$ may not be stable even if $F$ is stable (for instance, taking $E'$ to be the torsion subsheaf). In fact, $(E, Q)$ is stable if and only if $F$ is a stable vector bundle.

Next we prove that if $(E, Q)$ is stable (semistable), then $F$ is stable (semistable). For any subsheaf $F' \subset F$ such that $F/F'$ is torsion free, we have canonical morphism $\pi^*F' \to \pi^*F \to \pi^*\pi_*E \to E$. Let $E'$ be the image of $\pi^*F'$, one has the diagram

\[
\begin{array}{ccccccccc}
& & 0 & & 0 & & 0 & & \\
& & ↓ & & ↓ & & ↓ & & \\
0 & \longrightarrow & F' & \longrightarrow & \pi_*E' & \longrightarrow & x_0Q^{E'} & \longrightarrow & 0 \\
& & ↓ & & ↓ & & ↓ & & \\
0 & \longrightarrow & F & \longrightarrow & \pi_*E & \longrightarrow & x_0Q & \longrightarrow & 0 \\
& & ↓ & & ↓ & & ↓ & & \\
0 & \longrightarrow & F/F' & \longrightarrow & \pi_*(E/E') & \longrightarrow & x_0(Q/Q^{E'}) & \longrightarrow & 0 \\
& & ↓ & & ↓ & & ↓ & & \\
0 & & 0 & & 0 & & 0 & & \\
\end{array}
\]

which implies $E/E'$ torsion free outside $\{x_1, x_2\}$ (since $F/F'$ torsion free) and

$$\text{par}_m(F') = \text{par}_m(E') - \text{dim}(Q^{E'}), \quad \text{par}_m(F) = \text{par}_m(E) - \text{dim}(Q).$$

Thus, note that $rk(E') = rk(F')$ and $rk(E) = rank(F)$, one proves the lemma.
Lemma 3.3. Let \((E, Q)\) be a semistable GPS with \(E\) locally free and \(F = \phi(E, Q)\) the associated torsion free sheaf, if there exists an exact sequence

\[ 0 \to F_1 \to F \to F_2 \to 0 \]

with \(F_2\) semistable and \(\operatorname{par}_m(F_2) = \operatorname{par}_m(F)\). Then \((E, Q)\) is \(s\)-equivalent to a semistable \((E', Q')\) such that \(E'\) has torsion of dimension

\[ \dim(Q) - \alpha(F_1) - \alpha(F_2). \]

Proof. For any torsion free sheaf \(F\), we have a canonical exact sequence

\[ 0 \to F \to \pi_* \tilde{E} \to \tilde{Q} \to 0 \]

where \(\tilde{E} = \pi^* F / \text{Tor}(\pi^* F)\) and \(\dim(\tilde{Q}) = \alpha(F)\). If \(F = \phi(E, Q)\) with \(E\) locally free, then we have a commutative diagram

\[
\begin{array}{ccccccccc}
0 & & 0 & & \\
\downarrow & & \downarrow & & \\
0 & \to & F & \to & \pi_* \tilde{E} & \to & x_0 \tilde{Q} & \to & 0 \\
\downarrow & & \downarrow & & \downarrow & & \downarrow & & \\
0 & \to & F & \to & \pi_* E & \to & x_0 Q & \to & 0 \\
\downarrow & & \downarrow & & \downarrow & & \downarrow & & \\
\pi_* \tau & \to & x_0 Q' & & \\
\downarrow & & \downarrow & & \\
0 & & 0 & & \\
\end{array}
\]

where \(\tau = E / \tilde{E}\) and \(Q' = Q / \tilde{Q}\), the map \(\pi_* \tau \to x_0 Q'\) is defined such that the diagram is commutative, which has to be an isomorphism. This gives an exact sequence

\[ 0 \to (\tilde{E}, \tilde{Q}) \to (E, Q) \to (\tau, Q') \to 0 \]

in \(C_\mu\), thus \((E, Q)\) is \(s\)-equivalent to \((\tilde{E} \oplus \tau, \tilde{Q} \oplus Q')\). On the other hand, we consider the following commutative diagram

\[
\begin{array}{ccccccccc}
(3.1) & 0 & \to & \pi_* E_1 & \to & \pi_* \tilde{E} & \to & \pi_* E_2 & \to & 0 \\
\downarrow & & \downarrow & & \downarrow & & \downarrow & & \\
0 & \to & x_0 Q_1 & \to & x_0 \tilde{Q} & \to & x_0 Q_2 & \to & 0 \\
\downarrow & & \downarrow & & \downarrow & & \downarrow & & \\
\end{array}
\]
where \( E_1 = \pi^* F_1 / \text{Tor}(\pi^* F_1) \), \( \dim(Q_1) = a(F_1) \), the first two vertical sequences are the canonical exact sequences determined by \( F_1 \) and \( F \), and \( E_2 = \tilde{E} / E_1 \), \( Q_2 = \tilde{Q} / Q_1 \), the third vertical sequence is defined by demanding the diagram commutative, which has to be exact. It is easy to see that \( \mu_G[(E_2, Q_2)] = \mu_G[(\tilde{E}, \tilde{Q})] \) and \((E_2, Q_2)\) is semistable (since \( F_2 \) is so). Thus
\[
gr(\tilde{E}, \tilde{Q}) = gr(E_1, Q_1) \oplus gr(E_2, Q_2),
\]
which implies that \((E, Q)\) is \( s \)-equivalent to
\[
(E', Q') := (E_1 \oplus E_2 \oplus \tau, Q_1 \oplus Q_2 \oplus Q').
\]
One checks that \( \dim(Tor(E_2)) = a(F) - a(F_1) - a(F_2) \) by restricting the diagram (3.1) to point \( x_0 \) and counting the dimension of fibres (the first two vertical sequences remaining exact). Therefore
\[
\dim(Tor(E')) = \dim(\tau) + \dim(Tor(E_2)) = \dim(Q) - a(F_1) - a(F_2),
\]
we have proved the lemma.

Consider the family \( \rho^* \mathcal{E} = (\rho^* \mathcal{E}_1, \rho^* \mathcal{E}_2) \) of GPS over \( \tilde{R}^{ss} \) with the universal quotient \( \rho^*(\mathcal{E}_1 \oplus \mathcal{E}_2) \to Q \), using the finite morphism
\[
\pi \times I_{\tilde{R}^{ss}} : \tilde{X}_0 \times \tilde{R}^{ss} \to X_0 \times \tilde{R}^{ss},
\]
we can define a family \( \mathcal{F}_{\tilde{R}^{ss}} \) of semistable sheaves (Lemma 3.2) on \( X_0 \) by the exact sequence
\[
(3.2.) 0 \to \mathcal{F}_{\tilde{R}^{ss}} \to (\pi \times I_{\tilde{R}^{ss}})^* (\rho^* \mathcal{E}) \to x_0 Q \to 0
\]
Since \( \rho^* \mathcal{E} \) is flat over \( \tilde{R}^{ss} \) and \( Q \) locally free on \( \tilde{R}^{ss} \), \( \mathcal{F}_{\tilde{R}^{ss}} \) is a flat family over \( \tilde{R}^{ss} \). Thus we have a morphism
\[
\phi_{\tilde{R}^{ss}} : \tilde{R}^{ss} \to \tilde{R}^{ss} \to U_{X_0}
\]
such that \( \phi_{\tilde{R}^{ss}} \Theta u_{X_0} = \Theta \mathcal{F}_{\tilde{R}^{ss}} \) by Theorem 1.2 in the §1.

**Lemma 3.4.** The morphism \( \phi_{\tilde{R}^{ss}} \) induces a morphism
\[
\phi_{\mathcal{P}_{X_1, X_2}} : \mathcal{P}_{X_1, X_2} \to U_{X_0}
\]
such that \( \phi_{\mathcal{P}_{X_1, X_2}} \Theta u_{X_0} = \Theta \mathcal{P}_{X_1, X_2} \).

**Proof.** The proof is clear, we just remark that one can compute \( \Theta \mathcal{F}_{\tilde{R}^{ss}} = \Theta \tilde{R}^{ss} \) by the exact sequence (3.2) defining the sheaf \( \mathcal{F}_{\tilde{R}^{ss}} \).

Let \( U_{X_1, X_2} \) be the image of \( \mathcal{P}_{X_1, X_2} \) under the morphism \( \phi_{\mathcal{P}_{X_1, X_2}} \), then \( U_{X_1, X_2} \) is an irreducible component of \( U_{X_0} \) and \( \phi_{\mathcal{P}_{X_1, X_2}} \) is a finite morphism since it pulls back an ample line bundle to an ample line bundle. We will see that
\[
\phi_{\mathcal{P}_{X_1, X_2}} : \mathcal{P}_{X_1, X_2} \setminus \{D_1, D_2\} \to U_{X_1, X_2} \setminus \mathcal{W}_{r-1}
\]
is an isomorphism. Thus \( \phi_{\mathcal{P}_{X_1, X_2}} \) is the normalisation of \( U_{X_1, X_2} \). We have clearly the morphism
\[
\phi := \coprod_{\chi_1 + \chi_2 = \chi + r} \phi_{\mathcal{P}_{X_1, X_2}} : \mathcal{P} \to U_{X_0},
\]
which is the normalisation of \( U_{X_0} \). We copy Proposition 2.1 from [Su].
Proposition 3.1. With the above notation and denoting \( D_1(r - 1), D_2(r - 1), W_{r-1} \) by \( D_1, D_2 \) and \( W \), we have

1. \( \phi : P \to U_{X_0} \) is finite and surjective, and \( \phi(D_1(a)) = \phi(D_2(a)) = W_a \),
2. \( \phi(P \setminus \{D_1 \cup D_2\}) = U_{X_0} \setminus W \), and induces an isomorphism on \( P \setminus \{D_1 \cup D_2\} \),
3. \( \phi|_{D_1(a)} : D_1(a) \to W_a \) is finite and surjective,
4. \( \phi(D_1(a) \setminus \{D_1(a) \cap D_2 \cup D_1(a - 1)\}) = W_a \setminus W_{a-1} \), and induces an isomorphism on \( D_1(a) \setminus \{D_1(a) \cap D_2 \cup D_1(a - 1)\} \),
5. \( \phi : P \to U_{X_0} \) is the normalisation of \( U_{X_0} \),
6. \( \phi|_{D_1(a)} : D_1(a) \to W_a \) is the normalisation of \( W_a \),
7. \( \phi(D_1(a) \cap D_2) = W_{a-1} \), and \( W_{a-1} \) is the non-normal locus of \( W_a \).

Proof. In proving (4), we used Lemma 2.6 of [Su] to show that \( \phi \) induces a morphism

\[
\phi : D_1(a) \setminus \{D_1(a) \cap D_2 \cup D_1(a - 1)\} \to W_a \setminus W_{a-1}.
\]

But Lemma 2.6 in [Su] is not correct, we have to prove it without using the lemma (also to fix the gap in [Su]). We will use \( \lfloor \cdot \rfloor \) to denote the \( s \)-equivalent class of objects we are considering. For any \( [(E, Q)] \in D_1(a) \setminus \{D_1(a) \cap D_2 \cup D_1(a - 1)\} \), we can assume that \( E \) is a vector bundle by Proposition 2.5, and \( E_{x_2} \to Q \) is an isomorphism since \( [(E, Q)] \notin D_2 \). Thus \( \phi(E, Q) = F \in W_a \setminus W_{a-1} \) by Lemma 3.1 (3), we need to show \( [F] \notin W_{a-1} \). If it is not so, then \( F \) is \( s \)-equivalent to a semistable torsion free sheaf \( F' \in W(a - 1) \) and has an exact sequence

\[
0 \to F_1 \to F \to F_2 \to 0
\]

with \( par_{a}(F_2) = par_{a}(F) \) and \( F_2 \) stable. Thus \( gr(F') = gr(F_1) \oplus F_2 \) and (by Lemma 1.3)

\[
a - 1 \geq a(F') \geq a(F_1) + a(F_2).
\]

On the other hand, by Lemma 3.3, \( (E, Q) \) is \( s \)-equivalent to a semistable \( (E', Q') \) with \( dim(Tor(E')) = r - a(F_1) - a(F_2) \). By Proposition 2.5 (1), \( E' \) has no torsion at \( x_1 \) since \( [E', Q'] = [(E, Q)] \notin D_2 \). Hence, by Proposition 2.5 (1) again, \( (E', Q') \) is \( s \)-equivalent to a \( (\hat{E}, \hat{Q}) \) with \( \hat{E} \) locally free and

\[
rank(\tilde{E}_{x_1} \to \hat{Q}) \leq a(F_1) + a(F_2) \leq a - 1,
\]

we get the contradiction \( [(E, Q)] = [(\hat{E}, \hat{Q})] \in D_1(a-1) \). Thus \( \phi \) induces a morphism

\[
\phi : D_1(a) \setminus \{D_1(a) \cap D_2 \cup D_1(a - 1)\} \to W_a \setminus W_{a-1}
\]

The argument in [Su] for other statements goes through, only (7) is in doubt. This can be seen as follows, the fact \( \phi(D_1(a) \cap D_2) = W_{a-1} \) follows the local computation (see Proposition 3.9 of [B3]), and the non-normal locus of \( W_a \) is contained in \( W_{a-1} \) by the above (4). If \( W_{a-1} \) is not empty and not equal to the non-normal locus, there exists a non-empty irreducible component \( W_{a-1}^{X_1 \cap X_2} \) of \( W_{a-1} \) such that \( \phi|_{D_1(a)} \) is an isomorphism at the generic point of \( W_{a-1}^{X_1 \cap X_2} \). It is impossible since the fibre has at least two points (one is in \( D_1(a - 1) \cap D_2 \) by (3) of Lemma 3.1, another is in \( D_1(a) \cap D_2 \)).

Let \( I_Z \) denote the ideal sheaf of closed subscheme \( Z \) in a scheme \( X \). When \( Z \) is of codimension one (not necessarily a Cartier divisor), we set \( O_X(-Z) := I_Z \). If \( L \) is a line bundle on \( X \) and \( Y \) is a closed subscheme of \( X \), we denote \( L \otimes I_Z \) and the restriction \( I_Z \otimes O_Y \) of \( I_Z \) on \( Y \) by \( L(-Z) \) and \( O_Y(-Z) \). We have the straightforward generalisations of [Su, Lemma 4.2 and Proposition 4.1], whose proof we omit.
Lemma 3.5. Suppose given a seminormal variety \( V \), with normalization \( \sigma : \tilde{V} \to V \). Let the non-normal locus be \( W \), endowed with its reduced structure. Let \( \tilde{W} \) be set-theoretic inverse image of \( W \) in \( \tilde{V} \), endowed with its reduced structure. Let \( N \) be a line bundle on \( V \), and let \( \tilde{N} \) be its pull-back to \( \tilde{V} \) (\( \tilde{N} = \sigma^*N \)). Suppose \( H^0(\tilde{V}, \tilde{N}) \to H^0(\tilde{W}, \tilde{N}) \) is surjective. Then

1. There is an exact sequence

\[
0 \to H^0(\tilde{V}, \tilde{N} \otimes I_{\tilde{W}}) \to H^0(V, N) \to H^0(W, N) \to 0.
\]

2. If \( H^1(W, N) \to H^1(\tilde{W}, \tilde{N}) \) is injective, so is \( H^1(V, N) \to H^1(\tilde{V}, \tilde{N}) \).

Lemma 3.6. The following maps are surjective for any \( 1 \leq a \leq r \)

1. \( H^0(D_1(a), \Theta_P) \to H^0(D_1(a) \cap D_2 \cup D_1(a - 1), \Theta_P) \).

2. \( H^0(D_1(a), \Theta_P) \to H^0(D_1(a) \cap D_2, \Theta_P) \).

The above Lemma 3.6 tells us that the assumption (surjectivity) in Lemma 3.5 is satisfied for the situation: \( V = \mathcal{W}_a, \tilde{V} = D_1(a), \sigma = \phi|D_1(a) \) and \( N = \Theta_{U_x}|\mathcal{W}_a \). Thus we can use Lemma 3.5 to prove that

Proposition 3.2. We have a (noncanonical) isomorphism

\[
H^0(U_{X_0}, \Theta_{U_{X_0}}) \cong H^0(P, \Theta_P(-D_2)).
\]

Proof. Similar with the proof of Proposition 4.3 of [Su].

Proposition 3.3. Let \( \tilde{R}_F \subset \mathcal{H} \) be the open set consisting of \( (E, Q) \) with \( E \) locally free. Then

\[
H^0(\tilde{R}_{ss}, \Theta_{\tilde{R}_{ss}})^G = H^0(\mathcal{H}, \Theta_{\mathcal{H}})^G = H^0(\tilde{R}_F, \Theta_{\tilde{R}_F})^G,
\]

where \( G = (GL(V_1) \times GL(V_2)) \cap SL(V_1 \oplus V_2) \).

Proof. The first equality follows the following Lemma 3.7, the second equality follows the following Lemma 3.8 by taking \( V = \tilde{R}_{ss}, U = \mathcal{P}_{X_1, X_2}, V' = \tilde{R}_{ss} \cap \tilde{R}_F \) and \( U'' = \mathcal{P}_{X_1, X_2} \setminus \{D_1, D_2\} \) (one need here Proposition 1.4 to show that \( U'' \) is nonempty).

Lemma 3.7. Let \( V \) be a projective scheme on which a reductive group \( G \) acts, \( \mathcal{L} \) an ample line bundle linearising the \( G \)-action, and \( V_{ss} \) the open subscheme of semistable points. Let \( V' \) be a \( G \)-invariant closed subscheme of \( V_{ss} \), \( \tilde{V}' \) its schematic closure in \( V \). Then

1. \( V'_{ss} = V' \), and \( V' / \langle G \rangle \) is a closed subscheme of \( V_{ss} / \langle G \rangle \).

2. \( H^0(V_{ss}, \mathcal{L})^{\text{inv}} = H^0(W, \mathcal{L})^{\text{inv}} \), where \( W \) is an open \( G \)-invariant irreducible normal subscheme of \( V \) containing \( V_{ss} \) and \( (\cdot)^{\text{inv}} \) denotes the invariant subspace for an action of \( G \).

Proof. See Lemma 4.14 and Lemma 4.15 of [NR].
Lemma 3.8. Let \( V \) be a normal variety with a \( G \)-action, where \( G \) is a reductive algebraic group. Suppose a good quotient \( \pi : V \to U \) exists. Let \( \tilde{L} \) be a \( G \)-line bundle on \( V \), and suppose it descends as a line bundle \( L \) on \( U \). Let \( V'' \subset V' \subset V \) be open \( G \)-invariant subvarieties of \( V \), such that \( V' \) maps onto \( U \) and \( V'' = \pi^{-1}(U'') \) for some nonempty open subset \( U'' \) of \( U \). Then any invariant section of \( \tilde{L} \) on \( V' \) extends to \( V'' \).

Proof. See Lemma 4.16 of [NR].

Proposition 3.4. Let \( G_1 \) and \( G_2 \) be reductive algebraic groups acting on the normal projective schemes \( \tilde{V}_1, \tilde{V}_2 \) with ample linearizing \( L_1 \) and \( L_2 \). Suppose that \( L_1 \) and \( L_2 \) descend to \( \Theta_1 \) and \( \Theta_2 \). Then, for any open sets \( V_1 \supset \tilde{V}_1^{ss} \) and \( V_2 \supset \tilde{V}_2^{ss} \),

\[
H^0(V_1 \times V_2, L_1 \otimes L_2)^{G_1 \times G_2} = H^0(V_1, L_1)^{G_1} \otimes H^0(V_2, L_2)^{G_2}.
\]

Proof. Using Lemma 3.7 and next Lemma 3.9, we have

\[
H^0(V_1 \times V_2, L_1 \otimes L_2)^{G_1 \times G_2} = \left\{ H^0(V_1 \times V_2, L_1 \otimes L_2)^{G_1 \times \{id\}} \right\}^{\{id\} \times G_2}
\]

\[
= H^0(V_1^{ss} / G_1 \times V_2, \Theta_1 \otimes L_2)^{\{id\} \times G_2}
\]

\[
= H^0(V_1^{ss} / G_1 \times \tilde{V}_2^{ss} / G_2, \Theta_1 \otimes \Theta_2)
\]

\[
= H^0(V_1^{ss} / G_1, \Theta_1) \otimes H^0(\tilde{V}_2^{ss} / G_2, \Theta_2)
\]

\[
= H^0(V_1, L_1)^{G_1} \otimes H^0(V_2, L_2)^{G_2}.
\]

Lemma 3.9. Suppose \( V \to V//G \) is a good quotient and \( T \) is any variety with trivial \( G \)-action. Then \( V \times T \to V//G \times T \) is a good quotient.

Notation 3.1. For \( \mu = (\mu_1, \cdots, \mu_r) \) with \( 0 \leq \mu_1 \leq \cdots \leq \mu_1 \leq k-1 \), let

\[
\{d_i = \mu_{r_i} - \mu_{r_i+1}\}_{1 \leq i \leq r}
\]

be the subset of nonzero integers in \( \{\mu_i - \mu_{i+1}\}_{i=1}^{r-1} \). Then we define that

\[
r_i(x_1) = r_i, \quad d_i(x_1) = d_i, \quad l_{x_1} = l, \quad \alpha_{x_1} = \mu_r
\]

\[
r_i(x_2) = r - r_{l_{x_{i+1}}}, \quad d(x_2) = d_{l_{x_{i+1}}}, \quad l_{x_2} = l, \quad \alpha_{x_2} = k - \mu_1
\]

and for \( j = 1, 2 \), we set

\[
\bar{a}(x_j) = \left( \mu_r, \mu_r + d_1(x_j), \cdots, \mu_r + \sum_{i=1}^{l_{x_j} - 1} d_i(x_j), \mu_r + \sum_{i=1}^{l_{x_j}} d_i(x_j) \right)
\]

\[
\bar{n}(x_j) = (r_1(x_j), r_2(x_j) - r_1(x_j), \cdots, r_{l_{x_j}}(x_j) - r_{l_{x_j} - 1}(x_j)).
\]

We also define that

\[
\chi_1^\mu = \frac{1}{k}\left( \sum_{x \in I_1} \sum_{i=1}^{l_x} d_i(x)r_i(x) + r \sum_{x \in I_1} \alpha_x + r l_1 \right) + \frac{1}{k} \sum_{i=1}^{r} \mu_i
\]

\[
\chi_2^\mu = \frac{1}{k}\left( \sum_{x \in I_2} \sum_{i=1}^{l_x} d_i(x)r_i(x) + r \sum_{x \in I_1} \alpha_x + r l_2 \right) + r - \frac{1}{k} \sum_{i=1}^{r} \mu_i.
\]
One can check that the numbers defined in Notation 3.1 satisfy \((j = 1, 2)\)

\[
(3.3) \quad \sum_{x \in I_j \cup \{x_j\}} l_x \sum_{i=1}^{l_x} d_i(x) r_i(x) + r \sum_{x \in I_j \cup \{x_j\}} \alpha_x + r \ell_j = k \chi_j^\mu.
\]

**Notation 3.2.** For the numbers defined in Notation 3.1, let, for \(j = 1, 2,\)

\[
\mathcal{U}_{X_j}^\mu := \mathcal{U}_{X_j}(r, \chi_j^\mu, I_j \cup \{x_j\}, \{\tilde{n}(x), \tilde{a}(x)\}_{x \in I_j \cup \{x_j\}}, k)
\]

be the moduli space of \(s\)-equivalence classes of semistable parabolic bundles \(E\) of rank \(r\) on \(X_j\) and \(\chi(E) = \chi_j^\mu\), together with parabolic structures of type \(\{\tilde{n}(x)\}_{x \in I \cup \{x_j\}}\) and weights \(\{\tilde{a}(x)\}_{x \in I \cup \{x_j\}}\) at points \(\{x\}_{x \in I \cup \{x_j\}}\). We define \(\mathcal{U}_{X_j}^\mu\) to be empty if \(\chi_j^\mu\) is not an integer. Let

\[
\Theta_{\mathcal{U}_{X_j}^\mu} := \Theta(k, \ell_j, \{\tilde{n}(x), \tilde{a}(x), \alpha_x\}_{x \in I_j \cup \{x_j\}}, I_j \cup \{x_j\})
\]

be the theta line bundle.

**Theorem 3.1.** There exists a (noncanonical) isomorphism

\[
H^0(\mathcal{P}_{X_1 \cup X_2}, \Theta_{\mathcal{P}_{X_1 \cup X_2}}(-D_2)) \cong \bigoplus_{\mu} H^0(\mathcal{U}_{X_1}^\mu, \Theta_{\mathcal{U}_{X_1}^\mu} \otimes H^0(\mathcal{U}_{X_2}^\mu, \Theta_{\mathcal{U}_{X_2}^\mu})
\]

where \(\mu = (\mu_1, \cdots, \mu_r)\) runs through the integers \(0 \leq \mu_r \leq \cdots \leq \mu_1 \leq k - 1\).

**Proof.** By Proposition 3.3, one can show that

\[
H^0(\mathcal{P}_{X_1 \cup X_2}, \Theta_{\mathcal{P}_{X_1 \cup X_2}}(-D_2)) = H^0(\mathcal{R}_F, \Theta_{\mathcal{R}_F}(-D_2))^G.
\]

Note that \(\mathcal{O}_{\mathcal{R}_F}(-D_2) = \text{det} E_{x_2} \otimes (\text{det} \mathcal{Q})^{-1}\) and write \(\eta_{x_2} := (\text{det} E_{x_2})^{-1} \otimes \text{det} \mathcal{Q}\), we have

\[
H^0(\mathcal{R}_F, \Theta_{\mathcal{R}_F}(-D_2))^G = H^0(\mathcal{R}_{1 F} \times \mathcal{R}_{2 F}, \Theta_{\mathcal{R}_{1 F}} \otimes \Theta_{\mathcal{R}_{2 F}} \otimes (\text{det} E_{x_2})^k \otimes \rho^* (\eta_{x_2}^{k-1}))^G.
\]

Let

\[
\mathcal{R}_j^\mu := \times_{x \in I_j \cup \{x_j\}} \text{Flag}_{\tilde{n}(x)}(\mathcal{F}_x^j) \xrightarrow{p_j^\mu} \mathcal{R}_{j,F},
\]

then, by Lemma 4.6 of [Su], we have

\[
\rho^* (\eta_{x_2}^{k-1}) = \bigoplus_{\mu} p_1^\mu (L_1^\mu) \otimes p_2^\mu (L_2^\mu)
\]

where \(\mu = (\mu_1, \cdots, \mu_r)\) runs through the integers \(0 \leq \mu_r \cdots \leq \mu_1 \leq k - 1\) and

\[
L_1^\mu = (\text{det} E_{x_1}^1)^{\mu_r} \otimes \bigotimes_{i=1}^{l_{x_1}} (\text{det} \mathcal{Q}_{x_1,i})^{d_i(x_1)},
\]

\[
L_2^\mu = \bigotimes_{i=1}^{l_{x_1}} \mathcal{Q}_{x_1,i}.
\]
\[ L_2^\mu = (\det E_{x_2}^2)^{-\mu_1} \otimes \bigotimes_{i=1}^{l_x} (\det Q_{x_2,i})^{d_i(x_2)} \]

are line bundles on \( \mathcal{R}_1^\mu \times \mathcal{R}_2^\mu \). By the definition

\[ \Theta_{\mathcal{R}_1^\mu} := (\det R_{\mathcal{R}_1^\mu} E_j)^k \otimes \bigotimes_{x \in I_j \cup \{x_j\}} \left\{ (\det E_x^j)^{\alpha_x} \otimes \bigotimes_{i=1}^{l_x} (\det Q_{x,i})^{d_i(x)} \right\} \otimes (\det E_{y_1}^j)^{\ell_j}, \]

one sees easily that

\[ \Theta_{\mathcal{R}_1^\mu} = p_1^\mu \ast (\Theta_{\mathcal{R}_1^F}) \otimes L_1^\mu, \]

\[ \Theta_{\mathcal{R}_2^\mu} = p_2^\mu \ast (\Theta_{\mathcal{R}_2^F} \otimes (\det E_{x_2}^2))^k \otimes L_2^\mu. \]

Thus we have (for any \( \chi_1, \chi_2 \)) the equality

\[ H^0(P_{\chi_1, \chi_2}, \Theta_{P_{\chi_1, \chi_2}}(-D_2)) = H^0(\mathcal{R}_1^\mu \times \mathcal{R}_2^\mu, \Theta_{\mathcal{R}_1^\mu} \otimes \Theta_{\mathcal{R}_2^\mu})^G. \]

Since \( \mathbb{C}^* \times \mathbb{C}^* \) acts trivially on \( \mathcal{R}_1^\mu \times \mathcal{R}_2^\mu \), one can see that if

\[ H^0(\mathcal{R}_1^\mu \times \mathcal{R}_2^\mu, \Theta_{\mathcal{R}_1^\mu} \otimes \Theta_{\mathcal{R}_2^\mu})^G \neq 0, \]

then the \( \chi_j \) (\( j = 1, 2 \)) has to satisfy

\[ \sum_{x \in I_j \cup \{x_j\}} d_i(x) r_i(x) + r \sum_{x \in I_j \cup \{x_j\}} \alpha_x + r \ell_j = k \chi_j. \]

Therefore \( \chi_j \) has to be \( \chi_j^\mu \). In this case, \( \mathbb{C}^* \times \mathbb{C}^* \) acts trivially on the line bundle,

\[ H^0(\mathcal{R}_1^\mu \times \mathcal{R}_2^\mu, \Theta_{\mathcal{R}_1^\mu} \otimes \Theta_{\mathcal{R}_2^\mu})^G = H^0(\mathcal{R}_1^\mu \times \mathcal{R}_2^\mu, \Theta_{\mathcal{R}_1^\mu} \otimes \Theta_{\mathcal{R}_2^\mu})^{SL(V_1) \times SL(V_2)}. \]

Thus, by using Proposition 3.4, we can prove the theorem.

We end this paper by some remarks. In Notation 1.1, we chose and fixed the ample line bundle \( \mathcal{O}(1) \), the theta line bundle and the factorization are generally depend on this choice. In some cases, although the moduli space itself depends the choice, the theta bundle and the factorization (also the number of irreducible components of the moduli space) are independent of the choice. For example, when \( \chi = 0, |I| = 0 \), or the parabolic degree is zero, we can manage to the case: \( \ell_1 + \ell_2 = 0 \). In any case, one can see that \( \chi_1^\mu < n_1 + r \), thus, for any choice, there are only \( r \) components of moduli space contribute to the factorization.

The choice in Notation 1.1 has quit freedom, it is in general a choice of the partitions of \( \ell_1 + \ell_2 \). In particular, if we are only interested in studying moduli space, we can choose any \( \mathcal{O}(1) \).

**Corollary 3.1.** There is a choice of \( \mathcal{O}(1) \) such that the moduli space \( \mathcal{U}_{\chi_0} \) has \( r \) irreducible components and

\[ \mathcal{W}_1 = \emptyset. \]
In particular, when \( r = 2 \), \( \mathcal{U}_{X_0} \) has two normal crossing irreducible components.

Proof. One can easily choose \( \mathcal{O}(1) \) such that \( n_1 \) and \( n_2 \) are not integers. Thus \( n_j < \chi_j < n_j + r \) \((j = 1, 2)\) has only \( r \) possibility and each such \( \chi_j \) there is a nonempty irreducible component by Proposition 1.4. Recall (2.1)

\[
\begin{align*}
n_1 + r - \dim(Q^{E_2}) & \leq \chi(E_1) \leq n_1 + \dim(Q^{E_1}) \\
n_2 + r - \dim(Q^{E_1}) & \leq \chi(E_2) \leq n_2 + \dim(Q^{E_2}),
\end{align*}
\]

we see that \( \dim(Q^{E_j}) \geq \chi_j - n_j > 0 \), which means that

\[
\mathcal{D}_1(0) = \mathcal{D}_2(0) = \emptyset.
\]

Thus \( \mathcal{W}_0 = \emptyset \). In particular, when \( r = 2 \), the local model of moduli space at any non-locally free sheaf is \( \mathbb{C}[x, y]/(xy) \) by Lemma 1.4.

Remark 3.1. When \( r = 2 \) and \( \mathcal{O}(1) \) is chosen such that \( n_1 \) and \( n_2 \) are not integers, \( \mathcal{P} \) has two disjoint irreducible components \( \mathcal{P}_1 \) and \( \mathcal{P}_2 \), \( \mathcal{D}_j \subset \mathcal{P}_j \) \((j = 1, 2)\) is isomorphic to \( \mathcal{W} \subset \mathcal{U}_{X_0} \). Thus \( \mathcal{U}_{X_0} \) can be obtained from \( \mathcal{P}_1 \) and \( \mathcal{P}_2 \) by identifying \( \mathcal{D}_1 \) and \( \mathcal{D}_2 \).
