Abstract

Introduction: Study was conducted to isolate and identify the aerobic bacterial flora in burn wound patients admitted in and around hospitals of Davanagere. It also includes knowing common microbial pathogen involved in causing infection & antibiotic resistance pattern of isolates. Methods: The study was done on 100 patients admitted to burns wards in the following 2 Hospitals in Davangere: Chigateri Government Hospital and Bapuji Hospital. Sample is collected from patients in 2 different swabs, one for smear and another for culture. Each pair of swabs from single patient is analysed for 3 days of thorough investigations like Day 1: Examining sample under Gram’s stain and inoculating for sample for culture. Day 2: Noting the morphological characteristics of growth and further for microscopy. Day 3: Final identification of organism and biochemical tests for gram negative organisms. Result: According to the study results have been following in different categories like: Most common organisms found: Staphylococcus aureus and Pseudomonas aeruginosa. Staphylococcus aureus is most resistant to Penicillin G and 60% resistant to Methicillin whereas it is most sensitive to Chloramphenicol. It has various pattern of sensitivity for others various antibiotics. Conclusion: As we get results from the study, it can concluded that staphylococcus aureus and Pseudomonas aeruginosa are the most common organisms causing infections in burn patients, and these organisms are becoming resistant to most of the present day antibiotics like Penicillin G and Methicillin, treating resistant strains is the challenging job now a days.

Keywords: Burns, Infection, Methicillin Resistant Staph Aureus, Staphylococcus.
Methods

The present study will be carried out in Department of Microbiology, J J M Medical College, Davanagere. A total number of 100 patients admitted with different degree of burns will be studied. The cases are from Chigateri General Hospital and Bapuji hospital in Davanagere.

Criteria for inclusion in study: All cases of thermal burns who are hospitalized for treatment.

Criteria for exclusion from study: All cases of thermal burns on OPD basis. All cases of acid burns, electric burns and wounds other than thermal burns were excluded from study. The sample is collected under aseptic precautions from burn wound with help of dry sterile cotton swab sticks for bacteriological examination.

Two culture swabs each are obtained, one for smear study and other for aerobic culture. Culture swabs are taken from each patient and immediately brought to laboratory for investigation.

Results and Discussion

A total of 100 cases of burns wound infection were included in the present study. The study included 31 males and 69 females. The age ranged from 3-90 years. Most number of burns was seen between the age group of 22-45 years and most commonly in females. The male to female ratio was 0.4:1. In the 100 cases of the present study, a total of 127 organisms were isolated, accounting for an average of 1.3 organisms per case. Out of these 100 cases, 3 cases (3%) showed no growth on culture, 69 cases (69%) were monomicrobial in nature and remaining 28 cases (28%) were polymicrobial.

Out of these 127 isolates, all were aerobes and facultative anaerobes. The gram stain of all direct smears correlated well with the growth on culture. Of these 127 isolates, 57 (44.9%) were gram positive cocci and 70 (55.1%) were gram negative bacilli. Staphylococcus aureus was isolated most frequently (39.4%) followed by Pseudomonas aeruginosa (14.2%), Klebsiella pneumoniae (13.4%), Escherichia coli (8.7%) and Acinetobacter (7.9%).

Table-1: Aerobes isolated in the study group.

| Organisms                     | Number of cases | Percentage |
|-------------------------------|-----------------|------------|
| Staphylococci aureus          | 50              | 39.4       |
| Pseudomonas aeruginosa        | 18              | 14.2       |
| Klebsiella pneumoniae         | 17              | 13.4       |
| Escherichia coli              | 11              | 8.7        |
| Acinetobacter                 | 10              | 7.9        |
| Coagulase negative Staphylococci | 5        | 3.9        |
| Proteus mirabilis             | 5               | 3.9        |
| Klebsiella oxytoca            | 3               | 2.4        |
| Proteus vulgaris              | 3               | 2.4        |
| Providencia stuartii          | 3               | 2.4        |
| Enterococci                   | 2               | 1.6        |
Burn Wound Infections Related To Pure And Mixed Flora: The most common organism isolated in both pure and mixed flora is Staphylococcus aureus (50% and 27.1% respectively). In mixed flora, this was followed by Klebsiella pneumoniae (15.3%), Pseudomonas aeroginosa (11.9%) and Acinetobacter (11.9%). Likewise in pure flora, Staphylococcus aureus was followed by Pseudomonas aeroginosa (16.2%), Klebsiella pneumoniae (11.8%) and Proteus mirabilis (5.9%).

Burn Wound Infection In Relation To Depth: In relation to the depth of the burns wound, the most common organism isolated both in superficial and deep burns was Staphylococcus aureus (41.3% and 37.5% respectively). This is followed by Pseudomonas aeroginosa (15.9%) in superficial burn wounds and Klebsiella pneumoniae (15.6%) in deep burns.

Out of the 100 cases, 45 cases (45%) had 25-50% degree of burns which was followed by 40 cases (40%) having less than 25% degree of burns. The number of cases in relation to the degree of burns is given in pie chart below:

Antibiotic Susceptibility Pattern in Isolates: Staphylococcus aureus was most sensitive to Chloramphenicol (100%), Amikacin (92%) and Cefuroxime (68%). Out of the total of 50 isolates of Staphylococcus aureus 31 (62%) were Methicillin resistant Staphylococcus aureus (MRSA). All the MRSA strains were 100% sensitive to Vancomycin and Linezolid. Sensitivity pattern of the organism is shown in below table:

Table-2: Antibiotic susceptibility pattern in MRSA and MSSA isolates.

| Total (50) | Methicillin resistant R | SA (31)  | Methicillin sensitive | SA (19%)  |
|-----------|-------------------------|----------|-----------------------|----------|
| Penicillin| 32 (100%)               | 0        | 19 (100%)             | 0        |
| Amoxicillin| 30 (97%)             | 1 (3.22%)| 16 (84.2%)            | 3 (15.79%)|
| Erythromycin| 28(91.42%)       | 3 (9.67%)| 7 (36.84%)            | 12(63.16%)|
| Roxithromycin| 27 (87.1%)   | 4 (12.9%)| 5 (26.31%)            | 14(73.68%)|
| Ciprofloxacin| 29(93.54%)  | 2 (6.45%)| 7 (36.84%)            | 12(63.16%)|
| Ofloxacin| 23(74.19%)            | 8 (25.81%)| 6 (31.58%)            | 13(68.42%)|
| Gentamycin| 31 (100%)             | 0        | 14(73.68%)            | 5(26.31%) |
| Amikacin| 18 (58.06%)           | 13(41.93%)| 1(5.26%)              | 18(94.74%)|
| Chloramphenicol| 0                | 31 (100%)| 0                     | 19 (100%) |
| Cefotaxime| 16 (51.6%)            | 15 (48.39%)| 2 (10.52%)            | 17(89.47%)|
| Linezolid| 0                     | 31(100%) | 0                     | 19 (100%)  |
| Vancomycin| 0                    | 31 (100%)| 0                     | 19 (100%)  |

None of the cases of Staphylococcus aureus isolated was sensitive to Penicillin G. 4 cases (8%) of the Staphylococcus aureus isolated were sensitive to Gentamycin, while the rest (92%) was resistant. 49 cases (98%) were resistant to Nettimycin, Enterococcus species showed maximum susceptibility to Amikacin (92%), Cloxacillin (92%), Cefuroxime (68%) and Ofloxacin (52%), coagulase negative Staphylococcus were 100% sensitive to Chloramphenicol and Ceftriaxone. The gram negative enteric pathogens showed maximum sensitivity to Fluoroquinolones (Ofloxacin), aminoglycosides (Amikacin) and 3rd generation Cephalosporin (cefotaxime). Pseudomonas aeroginosa isolates were most sensitive to Amikacin (94.4%), Cefotaxime (77.8%), Amoxyccillin (77.8%), Cephalexin (66.7%) and Pfoxacin (61.1%).

Escherichia coli were most sensitive to Amikacin (100%), Ceftriaxone (81.8%), Ceftazidime (72.7%) and Ciprofloxacin (54.5%). Klebsiella pneumoniae isolates were susceptible to Amikacin (100%), Cotrimazole (94.1%), Ofloxacin (64.7%) and Ceftriaxone (58.8%). Acinetobacter isolates were most sensitive to Amikacin (100%), Carbenicillin (90%), Polymixin B (80%) and Ceftazidime (60%). Proteus mirabilis showed 80% sensitivity to Tetracycline, Amoxyccillin, Ofloxacin and Ceftazidime.

**Fig-4:** Sensitivity pattern of Staphylococcus aureus in burn wound infection.
Discussion

The burn wound is particularly susceptible to bacterial colonization and infection due to physical disruption of the normal skin barrier and the accompanying reduction in cell mediated immunity.

Infection in burns continues to be a great problem which is not yet solved and poses a challenge to the microbiologist and the surgeon in particular. In the present work an effort has been made to study the pattern of microbial infection in the burn wounds, with particular reference to the identification of the organism which is the most predominant cause of infection.

In present study, the majority of the population studied were within 20-45 years of age (62%) and the burned TBSA ranged within 25-50% (45%). This was similar to the study by Zorgani A et al (30 years and 50% respectively) [5]. The male to female ratio was 0.4:1 which was similar to a study done by Raj Kumar Gang et al (1:1.5) [6]. This was probably due to fact that the majority of severe flame burns occurred in females at home, either due to cooking gas accident or to clothes catching fire.

Out of the 100 cases studied, a total of 127 isolates were seen of which gram positive organisms composed of 57 (44.9%) and gram negative organisms 70 (55.1%). A single type of organisms either gram positive or gram negative were isolated from 69 cases according for 69% and more than one organism was isolated in 28 cases (28%) in the present study. Staphylococcus aureus was the most predominant organism in burn patients accounting for 39.4% of the total isolates. This is similar to the study by M.I. Lesseva et al (36.9%) and V.L. Yemul et al (41.5%) [7,8]. This is in contrast to the study conducted by A. Rastegar Lari et al, which reported Pseudomonas aeroginosa as the most predominant organism in burn patients [9].

According to our study, the frequency of Staphylococcal infection was almost the same both in superficial (41.3%) as well as deep burns (37.5%). This is similar to the work done by Lesseva et al who states that the frequency of staphylococcal infection did not seem to depend on the burn wound area and its colonization. Among the other gram positive organisms isolated, coagulase negative Staphylococci was the next common isolate accounting for 3.9% this was followed by Enterococci (1.6%). This is less compared to the study by H. Vindenes et al (21.5% and 11.3% respectively) and G Revathi et al and R L Bang et al where Enterococcus isolates accounted for 8.5% and 3.4% respectively [10-12].

Out of 50 strains of Staphylococcus aureus studied 31 (62%) were resistant to Oxacillin (MRSA) and the remaining 19 (38%) were sensitive (MSSA). All the MRSA isolates were sensitive to Vancomycin and Linezolid. The prevalence of MRSA is lower than that of W. Song et al and Sanyal et al but it is much higher than other reports.
Gram negative bacilli were the next, common organisms to follow Staphylococcus aureus. Among the 70 (55.1%) of gram negative pathogens, Pseudomonas aeruginosa was the commonest isolate accounting for 14.2% of total isolates which is in contrast to studies done by Barier et al [1]. Pseudomonas aeruginosa is a well organized cause of nosocomial infections among the patients with burns usually spread from patient to patient by direct contact, via staff.

The next common isolate in the present study was Klebsiella pneumoniae (13.4%). The relatively high incidence of Klebsiella pneumoniae may be due to frequent cross infections. The next commonest gram negative bacilli isolated were Escherichia coli (8.7%) and Acinetobacter (7.9%) which was more compared to study by G. Revathi et al [5] (5.1% and 1.1% respectively).

The other gram negative bacilli isolated in the present study were Proteus mirabilis (3.9%), Klebsiella oxytoca (2.4%), Proteus vulgaris (2.4%) and Providencia stuartii (2.4%). All these isolates have been reported by most of the workers.

The pattern of antibiotic sensitivity is a source of serious concern as many of the isolates are resistant to newly available antibiotics.

In the present study, Staphylococcus aureus was most sensitive to Chloramphenicol, Amikacin, Cloxacillin, Piperacillin, Cefuroxime, Ceftriaxone and Ofloxacin with a sensitivity rate of 100%, 92%, 92%, 78%, 68%, 68% and 52% respectively. None of the Staphylococcus aureus isolates were sensitive to Penicillin. About 62% of the Staphylococcus aureus isolates were Methicillin resistant Staphylococcus aureus (MRSA). This was more compared to Lesseva et al [13] (23.8%) but less compared to W. Song et al [10] (98%). A marked increase in the number of hospital infections due to MRSA has been recently reported in many countries. Lesseva et al [13] reported that 79.9% of the MRSA strains were isolated from the patients admitted for some time in the hospital.

In contrast to the relatively high sensitivity of MSSA strains to antimicrobial agents, multi drug resistance is common among the MRSA isolates. In our study, a great proportion of them were resistant to Gentamycin (100%), Penicillin (100%), Erythromycin (91.4%) and Ciprofloxacin (93.5%). This was similar to Lesseva et al [13] (82.2%, 100% and 71.1% respectively) but in contrast to their study concerning Ciprofloxacin (33.3%). All the MRSA isolates were fully sensitive to Vancomycin and Chloramphenicol which was again similar to Lesseva et al [13] (100%) and 66.7% respectively. Over 94.7% of MSSA were susceptible to Amikacin and 63.2% to Erythromycin. This was similar to Lesseva et al [13] (88% and 63.9% respectively). The higher incidence of MRSA strains in our study may probably due to the fact that MRSA either develops in the wounds during antibiotic therapy or enters the burns ward already resident in such patient.

Coagulase negative Staphylococci showed maximum susceptibility to Cloxacillin (100%), Amikacin (80%), Erythromycin (100%) and Cefuroxime (100%). They were resistant to Gentamycin (60%). Enterococcus species isolated

in the present study were sensitive to Amikacin (100%), Cloxacillin (100%) and Ceftriaxone (50%). They showed resistance to Gentamycin (100%).

The gram negative bacilli isolated in the present study were more sensitive to Amikacin, Cefotaxime, Amoxycillin, Ofloxacin and Ceftazidime. Pseudomonas aeruginosa which was the second commonest isolate (14.2%) of all the isolates was most susceptible to Amikacin (94.4%), Cephalaxin (66.7%) and Ceftazidime (55.6%). Of the 17 isolates of Klebsiella pneumoniae, 100% were susceptible to Amikacin, Ofloxacin (64.7%), Ceftriaxone (58.8%) and Tetracycline (52.9%).

Escherichia coli isolates demonstrated 63.6% sensitivity to Cefotaxime, 72.7% to Ceftazidime and 100% to Amikacin. Acinetobacter showed 100% susceptibility to Amikacin while Proteus mirabilis showed 80% susceptibility to Amikacin and 60% to Ciprofloxacin. The above mentioned organisms showed maximum resistance to antibiotics such as Gentamycin, Carbencillin, Co-trimoxazole and Cloramphenicol. This was similar to study done by G Revathi et al. [5].

Selective pressure of antimicrobials is thought to be a risk factor for the emergence of resistant organisms. Since the pharmacokinetics of the most antimicrobials is greatly altered in burn patients, it is suggested that the concentration of these drugs should be monitored in such patients and dosages should be adopted to avoid treatment failures and selection of resistant isolates.

Adequate bacteriological surveillance and monitorization from the moment of admission into the burns care unit, in order to diagnose any infection and study the colonization flora, is an important measure in the assessment of the more pathogenic or multi resistant organism.

To control hospital acquired infection in burn wards, over-crowding must be avoided as this is an important cause for cross infection in the burns ward. Strict hand washing is both before and after handling patients and restriction of the movement within the burns ward should be implemented.

**Conclusion**

The present study observed that the Staphylococcus aureus and Pseudomonas aeruginosa are the most common organisms causing infections in burn patients, and these organisms are becoming resistant to most of the present day antibiotics like Penicillin G and Methicillin.
