Sharp bounds for the first eigenvalue of a fourth order Steklov problem *

Simon Raulot and Alessandro Savo¹

September 21, 2018

Abstract
We study the biharmonic Steklov eigenvalue problem on a compact Riemannian manifold $\Omega$ with smooth boundary. We give a computable, sharp lower bound of the first eigenvalue of this problem, which depends only on the dimension, a lower bound of the Ricci curvature of the domain, a lower bound of the mean curvature of its boundary and the inner radius. The proof is obtained by estimating the isoperimetric ratio of non-negative subharmonic functions on $\Omega$, which is of independent interest. We also give a comparison theorem for geodesic balls.

1 Introduction
1.1 The biharmonic Steklov problem

Let $\Omega$ be a compact, connected Riemannian manifold of dimension $n$ with smooth boundary $\partial \Omega$. We consider the following fourth order eigenvalue boundary problem

\[
\begin{cases}
\Delta^2 f = 0 & \text{on } \Omega \\
f = 0, \quad \Delta f = q \frac{\partial f}{\partial N} & \text{on } \partial \Omega,
\end{cases}
\]

where $N$ is the inward unit normal and $\Delta = -\text{div}\nabla$ is the Laplacian defined by the Riemannian metric of $\Omega$; the sign convention is that, in Euclidean space, $\Delta = -\sum_j \partial^2 / \partial x_j^2$.

The first eigenvalue of (1) has the following variational characterization:

\[
q_1(\Omega) = \inf \left\{ \frac{\int_{\Omega} (\Delta f)^2}{\int_{\partial \Omega} (\frac{\partial f}{\partial N})^2} : f = 0 \text{ on } \partial \Omega \right\}.
\]

This problem was introduced by Kuttler and Sigillito [7] and Payne [8]. For a review of the main facts about \( q_1(\Omega) \), also when the boundary is not smooth, we refer to [1]; in this paper, we always assume smoothness of \( \partial \Omega \). For a recent lower bound of \( q_1 \), see [12]. It is known that \( q_1(\Omega) \) is positive and simple, and that any first eigenfunction \( f \) does not change sign on \( \Omega \) (see [6]). Moreover, it turns out that \( q_1(\Omega) \) has the following interesting characterization in terms of harmonic functions:

\[
q_1(\Omega) = \inf \left\{ \frac{\int_{\partial \Omega} h^2}{\int_{\Omega} h^2} : h \text{ is harmonic on } \Omega \right\}.
\]

The infimum in (3) is attained precisely when \( h = \Delta f \), where \( f \) is a first eigenfunction of (1) (see [6]). In particular, taking \( h = 1 \) one observes the following upper bound by the isoperimetric ratio:

\[
q_1(\Omega) \leq \frac{|\partial \Omega|}{|\Omega|},
\]

where \( |\Omega| \) (resp. \( |\partial \Omega| \)) denotes the volume of \( \Omega \) (resp. of \( \partial \Omega \)) for the induced Riemannian measure. It turns out that, if \( \Omega \) is a geodesic ball in a simply connected manifold of constant sectional curvature, then equality holds in (4) (see Theorem 2 below).

The main scope of this paper is to give sharp lower bounds for \( q_1(\Omega) \). Let us review some known results. Isoperimetric inequalities for plane domains were given in [6], [7] and [8]. In [8], Payne considers convex domains in \( \mathbb{R}^n \) and shows that, if \( w_\Omega \) is the minimal distance between two parallel hyperplanes which enclose \( \Omega \), then

\[
q_1(\Omega) \geq \frac{2}{w_\Omega}.
\]

So, convex Euclidean domains which are “thin” have large first eigenvalue. We will prove below that this is a quite general principle which applies to a large class of manifolds.

For Riemannian manifolds, Wang and Xia prove in [12] that, if \( \Omega \) has nonnegative Ricci curvature, and \( \partial \Omega \) has mean curvature bounded below by \( H > 0 \) (hence positive everywhere), then

\[
q_1(\Omega) \geq nH,
\]

with equality if and only if \( \Omega \) is a Euclidean ball. We should mention that inequality (6) is also a consequence of a lower bound of \( q_1(\Omega) \) by the first eigenvalue of a certain Steklov problem for differential forms, recently proved by the authors (see Theorem 10 in [10]).

Wang and Xia proof of (6) makes use of the Reilly formula: this approach, however, seems to be hard to apply when the curvature of the domain (or the mean curvature of its boundary) assume negative values somewhere.

In this paper, using a Laplacian comparison argument, and a symmetrization procedure developed in [11], we give a sharp, explicit lower bound of \( q_1(\Omega) \): see Theorem 2. The
method produces a positive lower bound for all compact Riemannian manifolds with boundary, and in particular it applies also in negative curvature. Moreover, our bound implies (and actually improve) both (5) and (6): see Remarks 4 and 6. Finally, we prove a comparison theorem for geodesic balls, analogous to Cheng comparison theorem for the first Dirichlet eigenvalue: see Theorem 9.

1.2 The main estimate

Let $S$ be the shape operator of $\partial \Omega$ relative to the inner unit normal $N$: recall that if $X$ is a vector tangent to $\partial \Omega$, then $S(X) = -\nabla_X N$, where $\nabla$ is the Levi-Civita connection of $\Omega$. The mean curvature $\mathcal{H}$ of $\partial \Omega$ is the function defined by

$$\mathcal{H} = \frac{1}{n-1} \text{tr} S,$$

and the sign convention is that $\mathcal{H} = 1$ for the boundary of the unit ball in $\mathbb{R}^n$.

**Definition 1.** Let $K$ and $H$ be arbitrary real numbers. We say that the $n$-th dimensional domain $\Omega$ has curvature bounds $(K, H)$ if:

- the Ricci curvature of $\Omega$ is bounded below by $(n-1)K$,
- the mean curvature of $\partial \Omega$ is bounded below by $H$.

Let $R$ be the inner radius of $\Omega$, defined as the maximal radius of a ball included in $\Omega$. Clearly:

$$R = \max \{ \text{dist}(x, \partial \Omega) : x \in \Omega \}.$$

We then prove that $q_1(\Omega)$ is uniformly bounded below by a positive constant depending only on $K, H, n, R$. To make this constant explicit, introduce the function:

$$s_K(r) = \begin{cases} \frac{1}{\sqrt{|K|}} \sin (r \sqrt{|K|}) & \text{if } K > 0, \\ r & \text{if } K = 0, \\ \frac{1}{\sqrt{|K|}} \sinh (r \sqrt{|K|}) & \text{if } K < 0, \end{cases}$$

and let

$$\Theta(r) = (s_K'(r) - Hs_K(r))^{n-1}.$$  \hfill (7)

Note that $\Theta$ depends on $K$ and $H$, and that $\Theta(0) = 1$. In Proposition 14 it will be shown that $\Theta$ is positive on $[0, R)$, and that $\Theta(R) = 0$ if and only if $\Omega$ is a ball in the simply connected manifold $M_K$ of constant curvature $K$ (we will call $M_K$ a *space form*).

Here is the main estimate.
Theorem 2. Assume that $\Omega$ has curvature bounds $(K,H)$ (see Definition 1). Let $\Theta$ be the function defined in (8). Then:

$$q_1(\Omega) \geq \frac{1}{\int_0^R \Theta(r) \, dr}. \tag{9}$$

The inequality is sharp: it reduces to an equality when $\Omega$ is a ball in the space form $M_K$ of constant curvature $K$ (in this case, the right-hand side is the isoperimetric ratio $|\partial \Omega|/|\Omega|$).

The proof will be given in Sections 1.6 and 2. It turns out that, besides balls in $M_K$, equality holds also for other domains, like flat cylinders (see Corollary 5); however, we will not study the complete equality case of Theorem 2. The proof of Theorem 2 relies on an estimate of the isoperimetric ratio of non-negative subharmonic functions, which is of independent interest (see Theorem 10).

In Section 3 we have explicated a number of lower estimates of $q_1(\Omega)$, which follow directly from (9).

Let us see some other consequences of Theorem 2. For simplicity we assume $K \in \{0, 1, -1\}$ so that the space form $M_K$ is, respectively, the Euclidean space $\mathbb{R}^n$, the sphere $S^n$ and the hyperbolic space $H^n$.

**Corollary 3.** Assume that $\Omega$ has curvature bounds $(K,H)$, and that:

a) $H > 0$ if $K = 0$;
b) $H \in \mathbb{R}$ if $K = 1$;
c) $H > 1$ if $K = -1$.

Let $\bar{\Omega}$ be the unique ball in $M_K$ having boundary of (constant) mean curvature $H$. Then

$$q_1(\Omega) \geq q_1(\bar{\Omega}) = \frac{|\partial \bar{\Omega}|}{|\bar{\Omega}|},$$

with equality if and only if $\Omega = \bar{\Omega}$.

For the proof, see Section 3.1.

**Remark 4.** Corollary 3 can be seen as a generalization of the Wang-Xia bound (6), which is the statement in (a); in fact, the Euclidean ball of mean curvature $H$ has first eigenvalue $q_1(\bar{\Omega}) = |\partial \bar{\Omega}|/|\bar{\Omega}| = nH$. However, the main bound (9) is actually stronger and a straightforward calculation gives

$$q_1(\Omega) \geq \frac{nH}{1 - (1 - RH)^n} \geq nH$$

because $1 - RH \geq 0$, with equality only for Euclidean balls (see Theorem 12a).
Corollary 3b applies to spherical domains; in particular we get that, if \( \Omega \) is a domain in \( S^n \) having boundary of non-negative mean curvature, then the ball \( \bar{\Omega} \) is just the hemisphere and one has:

\[
q_1(\Omega) \geq q_1(\bar{\Omega}) = \frac{2|S^{n-1}|}{|S^n|}.
\]

with equality if and only if \( \Omega = \bar{\Omega} \).

Finally, Corollary 3c implies that, for all domains in \( H^n \) with mean curvature bounded below by 1, one has the simple bound

\[
q_1(\Omega) > n - 1,
\]

and the equality is asymptotically approached by the hyperbolic ball of radius \( r \), as \( r \to \infty \): this is seen immediately by estimating the isoperimetric ratio of hyperbolic balls (but see also Theorem 13).

The lower bound (11) is a kind of Mc Kean inequality for the eigenvalue \( q_1(\Omega) \) (the original Mc Kean inequality states that the first eigenvalue of the Laplacian for the Dirichlet boundary conditions satisfies the bound \( \lambda_1(\Omega) \geq (n - 1)^2/4 \) for all domains in \( H^n \)).

1.3 Lower bounds by the inner radius

Perhaps, a more interesting feature of the main lower bound (9) is its dependence on the inner radius. We first illustrate this fact on a special case (see Theorem 12b for a proof).

**Corollary 5.** Assume that \( \Omega \) has non-negative Ricci curvature and that \( \partial \Omega \) has non-negative mean curvature. Then:

\[
q_1(\Omega) \geq \frac{1}{R}.
\]

Equality holds for flat cylinders, that is, for all Riemannian products \( \Omega = N \times [0, 2R] \) where \( N \) is any closed manifold and \( R > 0 \).

**Remark 6.** Corollary 5 applies to mean-convex (in particular, convex) Euclidean domains, and in that case it improves the bound (5). In fact, just observe that, if the strip between two parallel planes contains \( \Omega \), it contains a ball of maximal radius inside \( \Omega \). Hence \( w_\Omega \geq 2R \) which implies

\[
q_1(\Omega) \geq \frac{1}{R} \geq \frac{2}{w_\Omega}.
\]

However, very often one has \( 1/R > 2/w_\Omega \): for example, if \( \Omega \) is close to the equilateral triangle circumscribed to the unit disk one has \( w_\Omega \sim 3 \) while \( 2R \sim 2 \).

We then observe the following rough, general estimate.
Corollary 7. Let $\Omega$ be a domain with curvature bounds $(K, H)$. Assume that $R \leq 1$. Then:

$$q_1(\Omega) \geq \frac{c}{R},$$

for a positive constant $c$ depending only on $K, H$ and $n = \dim \Omega$.

For the proof, let $\bar{R} \in (0, \infty]$ be the first positive zero of $\Theta$: then we know that $R \leq \bar{R}$ (see Proposition 14). Let $C$ be the maximum value of $\Theta$ on the interval $[0, \min\{1, \bar{R}\}]$ (note that $C$ depends only on $K, H$ and $n$). Since

$$\int_0^R \Theta(r) \, dr \leq RC,$$

the corollary follows from Theorem 2 by taking $c = 1/C$.

In conclusion, if the Ricci curvature of $\Omega$ and the mean curvature of $\partial \Omega$ are uniformly bounded below, then $q_1(\Omega)$ becomes larger and larger as the inner radius $R$ tends to zero. With that in mind, the following general principle holds:

Remark 8. Thin domains have large first eigenvalue.

Finally, we remark that a lower bound of the mean curvature is essential in order to have a positive, uniform lower bound of $q_1(\Omega)$. In fact, let $B_r$ be the ball of radius $r$ in the unit sphere $S^n$. As $r \to \pi$ (the diameter of the sphere) we see that $|\partial B_r|$ tends to zero while the volume of $B_r$ approaches the volume of the sphere. The isoperimetric ratio $|\partial B_r|/|B_r|$ tends to zero, and, by (4), so does $q_1(B_r)$. Note however that the mean curvature of $\partial B_r$ tends to $-\infty$ as $r \to \pi$.

1.4 An upper bound of Cheng type

Let $M$ be a manifold with Ricci curvature of $M$ bounded below by $(n-1)K$, with $K \in \mathbb{R}$, and $B(x_0, r)$ be the geodesic ball in $M$ with center $x_0$ and radius $r$. Cheng proves in [2] the following comparison theorem for the first eigenvalue of the Laplacian under Dirichlet boundary conditions:

$$\lambda_1(B(x_0, r)) \leq \lambda_1(B_K(r)),$$

where $B_K(r)$ is any ball of radius $r$ in $M_K$, the space form of constant curvature $K$. It turns out that the same fact holds for $q_1$. Precisely:

Theorem 9. Assume that the Riemannian manifold $M$ has Ricci curvature bounded below by $(n-1)K$. Then, for all $x_0 \in M$ and for all $r$ less than the injectivity radius of $M$ at $x_0$, we have:

$$q_1(B(x_0, r)) \leq q_1(B_K(r)),$$

where $B_K(r)$ is any ball of radius $r$ in $M_K$. 

6
The assumption on the injectivity radius is done to insure that the ball $B(x_0, r)$ has smooth boundary. For the proof, see Section 2.3.

1.5 Boundary integral estimates

The proof of Theorem 2 is obtained by estimating the isoperimetric ratio (that is, the quantity $\int_{\partial \Omega} h / \int_{\Omega} h$) of any non-negative subharmonic function $h$ on $\Omega$. Precisely, the following estimate holds.

**Theorem 10.** Let $\Omega$ be a compact domain with smooth boundary. Assume that $\Omega$ has curvature bounds $(K, H)$. If $h$ is any non-trivial, non-negative subharmonic function on $\Omega$ (that is, $h \geq 0$ and $\Delta h \leq 0$ on $\Omega$), then

$$\frac{\int_{\partial \Omega} h}{\int_{\Omega} h} \geq \frac{1}{\int_{0}^{K} \Theta(r) \, dr},$$

where $\Theta$ is defined in (8).

If $\Omega$ is a ball in the space form $M_K$ and $h$ is harmonic, then equality holds; in that case (12) reduces to the classical mean-value lemma for harmonic functions on balls:

$$\frac{\int_{\partial \Omega} h}{\int_{\Omega} h} = \frac{|\partial \Omega|}{|\Omega|}.$$ 

The proof of Theorem 10 is given in Section 2.

In Theorem 3.1 of [3], P. Guerini and the second author give a lower bound of $\int_{\partial \Omega} h / \int_{\Omega} h$ when $h$ is non-negative and satisfies $\Delta h \leq \mu h$ for $\mu$ less than a suitable positive constant. However, this bound is sharp only when $K = H = 0$.

Let us sketch the idea of the proof of (12). Introduce the function $F : [0, \infty) \to \mathbb{R}$ defined as

$$F(r) = \int_{\{\rho > r\}} h,$$

where $\{\rho > r\}$ denotes the set of points of $\Omega$ at distance greater than $r$ from the boundary. As $h$ is nonnegative and subharmonic, the function $F$ is shown to satisfy the following simple differential inequality:

$$F'' - \frac{\Theta'}{\Theta} F' \geq 0$$

in the sense of distributions. Integrating this inequality twice one gets the desired bound. All this will be explained in detail in the next section. This symmetrization procedure has been used in [11] and [3] to get spectral estimates in various contexts.
1.6 Proof of Theorem 2

Let $f$ be a first eigenfunction of problem (1), and set $g = \Delta f$. Then $g$ is harmonic on $\Omega$ and on $\partial \Omega$ one has $g = q_1(\Omega) \partial f / \partial N$. Now:

$$\int_{\Omega} g^2 = \int_{\Omega} (\Delta f)^2 = q_1(\Omega) \int_{\partial \Omega} \left( \frac{\partial f}{\partial N} \right)^2 = \frac{1}{q_1(\Omega)} \int_{\partial \Omega} g^2,$$

that is

$$q_1(\Omega) = \frac{\int_{\partial \Omega} g^2}{\int_{\Omega} g^2}.$$

As $g$ is harmonic, the function $h = g^2$ is subharmonic and non-negative. Then, applying Theorem 10 to $h$ we immediately obtain the assertion:

$$q_1(\Omega) \geq \frac{1}{\int_0^R \Theta(r) \, dr}.$$

Finally, if $\Omega$ is a geodesic ball in $M_K$, then the right-hand side of the previous inequality is the isoperimetric ratio $|\partial \Omega|/|\Omega|$ (see (22)). On the other hand, by (4), one has also $q_1(\Omega) \leq |\partial \Omega|/|\Omega|$, hence equality holds.

2 Proofs

2.1 Known facts on the distance function

The proof of Theorem 10 is based on the calculation of the second derivative, in the distributional sense, of the function $F$ defined in (13). This calculation was done in [11] and involves the Laplacian of the distance function to the boundary: see Proposition 11 below. In this section we state the results we need from [11]; for convenience of the reader, we recall the main arguments of the proof in the Appendix below.

Let $\Omega$ be a compact domain with smooth boundary and let $\rho : \Omega \to [0, \infty)$ be the distance function to the boundary:

$$\rho(x) = \text{dist}(x, \partial \Omega).$$

Then $\rho$ is only Lipschitz regular, and $|\nabla \rho| = 1$ almost everywhere on $\Omega$. The set where $\rho$ is singular (i.e. not $C^1$) is called the cut-locus and is denoted by $\text{Cut}(\partial \Omega)$: it is closed, and has measure zero in $\Omega$. Since the boundary of $\Omega$ is assumed smooth, the function $\rho$ is smooth on a strip near $\partial \Omega$, precisely on $\rho^{-1}[0, \text{inj}(\partial \Omega))$ where $\text{inj}(\partial \Omega) = \text{dist}(\partial \Omega, \text{Cut}(\partial \Omega))$ is the injectivity radius of the normal exponential map.

We define the distributional Laplacian of $\rho$ in the usual way:

$$(\Delta \rho, f) = \int_{\Omega} \rho \Delta f,$$
for all smooth functions \( f \) compactly supported in the interior of \( \Omega \), where \((\cdot, \cdot)\) denotes the duality between a test-function and a distribution. We want to estimate \( \Delta \rho \) from below. To that end, assume that \( \Omega \) has Ricci curvature bounded below by \((n - 1)K\), that \( \partial \Omega \) has mean curvature bounded below by \( H \) and let \( \Theta \) be the function defined in (8).

Then one has the following bound, proved in Lemma 3.5 of [11]:

\[
\Delta \rho \geq -\Theta' \circ \rho \tag{14}
\]

as distributions on \( \Omega \). This means that, if \( f \) is any non-negative test-function:

\[
(\Delta \rho, f) \geq -\left(\Theta' \circ \rho, f\right) = -\int_\Omega f \left(\Theta' \circ \rho\right). \tag{15}
\]

We remark that if \( \Omega \) is a ball in a space form \( M_K \) then the distance function \( \rho \) is smooth (except at the center of the ball), the function \( \Delta \rho \) is radial (i.e. it depends only on \( \rho \)) and equality holds in (14).

For \( r \geq 0 \), we denote by \( \{\rho > r\} \) (respectively, \( \{\rho = r\} \)) the set of points of \( \Omega \) at distance greater (respectively, equal) to \( r \) from \( \partial \Omega \). Let \( \phi \) be a smooth function on \( \Omega \) and let \( F : [0, \infty) \rightarrow \mathbb{R} \) be defined by:

\[
F(r) = \int_{\{\rho > r\}} \phi.
\]

Then \( F \) is Lipschitz regular and vanishes for \( r \geq R \), where \( R \) is the inner radius of \( \Omega \). By the formula of co-area, since \( |\nabla \rho| = 1 \) almost everywhere, we have:

\[
F(r) = \int_r^\infty \int_{\{\rho = s\}} \phi \, dH_{n-1} \, ds,
\]

where \( dH_{n-1} \) is the \((n - 1)\)-th dimensional Hausdorff measure of the level set \( \{\rho = s\} \). Then:

\[
F'(r) = -\int_{\{\rho = r\}} \phi \, dH_{n-1}, \tag{16}
\]

a.e. on \([0, \infty)\). Note that, as \( \rho \) is smooth near the boundary, the function \( F \) is smooth near \( r = 0 \): precisely on the interval \([0, \text{inj}(\partial \Omega)]\), where \( \text{inj}(\partial \Omega) \) is the injectivity radius of the normal exponential map. On that interval one has \( F'(r) = -\int_{\{\rho = r\}} \phi \) because \( dH_{n-1} \) coincides with the Riemannian measure of the smooth hypersurface \( \{\rho = r\} \).

Here is the main result we need.

**Proposition 11.** ([11], formula (7) p. 517) Let \( \phi \) be a smooth function on \( \Omega \), and \( F(r) = \int_{\{\rho > r\}} \phi \). Then, as distributions on \((0, \infty)\):

\[
F''(r) = -\int_{\{\rho > r\}} \Delta \phi + \rho_* (\phi \Delta \rho), \tag{17}
\]
where $\rho_*(\phi \Delta \rho)$ denotes the distribution on $(0, \infty)$ given by the push-forward of $\phi \Delta \rho$ by $\rho$. This means that, if $\psi$ is a test-function on $(0, \infty)$, then, by definition:

$$(\rho_*(\phi \Delta \rho), \psi) = (\phi \Delta \rho, \psi \circ \rho) = \left(\Delta \rho, \phi(\psi \circ \rho)\right),$$

where on the right hand side $(\cdot, \cdot)$ denotes the duality in $\Omega$. We remark that $\psi \circ \rho$ is only Lipschitz regular; but (see the Appendix below) $\Delta \rho$ is a zero-order distribution (that is, a Radon measure): then, the right-hand side is well-defined because it is just the integral of the continuous function $\phi(\psi \circ \rho)$ with respect to the measure $\Delta \rho$.

### 2.2 Proof of Theorem 10

Fix a non-negative subharmonic function $h$ on $\Omega$, and consider the function

$$F(r) = \int_{\{\rho > r\}} h.$$

Let $\psi$ be a non-negative test-function on $(0, \infty)$. Then, by (14), the co-area formula and (16) we see that:

$$(\rho_*(h \Delta \rho), \psi) = \left(\Delta \rho, h(\psi \circ \rho)\right)$$

$$\geq -\left(\Theta' \circ \rho, h(\psi \circ \rho)\right)$$

$$= -\int_{\Omega} h(\psi \circ \rho) \left(\Theta' \circ \rho\right)$$

$$= -\int_0^\infty \psi(r) \frac{\Theta'}{\Theta}(r) \int_{\{\rho = r\}} h dH_{n-1} dr$$

$$= \int_0^\infty \psi(r) \frac{\Theta'}{\Theta}(r) F'(r) dr$$

$$= \left(\Theta' F', \psi\right)$$

that is

$$\rho_*(h \Delta \rho) \geq \frac{\Theta'}{\Theta} F'$$

as distributions on the half-line. We apply Proposition 11 to $\phi = h$; as $\Delta h \leq 0$ we conclude by (18) that

$$F'' - \frac{\Theta'}{\Theta} F' \geq 0$$

(19)
as distributions on \((0, \infty)\).

Now set \(a = \int_\Omega h\) and \(b = \int_{\partial \Omega} h\). As \(\{\rho > r\}\) is empty for \(r \geq R\), we have:

\[
F(0) = a, \quad F'(0) = -b, \quad F(r) = 0 \quad \text{if} \quad r \geq R.
\]

We first assume that \(\Theta(R) > 0\); we know that \(\Theta\) is positive on \([0, R]\) by Proposition 14 in the Appendix and then the function

\[
G = \frac{F'}{\Theta}
\]

is integrable. By (19), the distribution \(G'\) is non-negative: it is a simple fact that then \(G\) is non-decreasing on a set of full measure in \([0, R]\). As \(G\) is regular near \(r = 0\) and \(\Theta(0) = 1\) we must have \(G(r) \geq G(0) = -b\) a.e. on \([0, R]\), which implies that

\[
F'(r) + b\Theta(r) \geq 0
\]

almost everywhere. We integrate (20) on \((0, R)\) to obtain \(b \int_0^R \Theta(r) \, dr \geq a\). Finally:

\[
\frac{\int_{\partial \Omega} h}{\int_\Omega h} \geq \frac{1}{b} \frac{\int_0^R \Theta(r) \, dr}{a}
\]

which gives the assertion.

Now assume that \(\Theta(R) = 0\): then, again by Proposition 14, \(\Omega\) is a ball of radius \(R\) in \(M_K\). In that case, the injectivity radius is just the radius of the ball, the function \(F\) is smooth on \([0, R]\) and the proof carries over as well.

Finally, assume that \(h\) is harmonic and \(\Omega\) is a ball in \(M_K\): we have equality in (14) and then we have equality at every step of the proof, so that

\[
\frac{\int_{\partial \Omega} h}{\int_\Omega h} = \frac{1}{\int_0^R \Theta(r) \, dr}.
\]

Note that applying the above to \(h = 1\) we obtain:

\[
\frac{1}{\int_0^R \Theta(r) \, dr} = \frac{\partial \Omega}{|\Omega|}.
\]

In fact, \(\Theta\) is the density of the Riemannian measure in normal coordinates around \(\partial \Omega\) (see the Appendix below).
2.3 Proof of Theorem 9

Assume that $M$ is a complete Riemannian manifold with Ricci curvature bounded below by $(n-1)K$, and let $M_K$ be the space form of constant curvature $K$. For any $x_0 \in M$ the well-known Bishop-Gromov inequality (see for example [9], Lemma 1.6) states that the function:

$$V(r) = \frac{|B(x_0, r)|}{|B_K(r)|}$$

is non-increasing on $(0, \infty)$, and tends to 1 as $r \to 0$ (here $B_K(r)$ is any ball of radius $r$ in $M_K$). If $r < \text{inj}(x_0)$ we have $\frac{d}{dr}|B(x_0, r)| = |\partial B(x_0, r)|$, $\frac{d}{dr}|B_K(r)| = |\partial B_K(r)|$ and as $V'(r) \leq 0$ we obtain:

$$\frac{|\partial B(x_0, r)|}{|B(x_0, r)|} \leq \frac{|\partial B_K(r)|}{|B_K(r)|}.$$

Now, from inequality (4) (which is an equality for geodesic balls in a space form) we have:

$$q_1(B(x_0, r)) \leq \frac{|\partial B(x_0, r)|}{|B(x_0, r)|} \leq \frac{|\partial B_K(r)|}{|B_K(r)|} = q_1(B_K(r))$$

which proves the assertion.

3 Explicit estimates

We consider the cases where $K = \{0, -1, 1\}$.

First, assume that $\Omega$ is a domain with non-negative Ricci curvature, that is, $K = 0$. One has:

$$\Theta(r) = (1 - Hr)^{n-1}.$$

The integral $\int_0^R \Theta$ can be explicitly computed, and from Theorem 2 one gets easily:

**Theorem 12.** Let $\Omega^n$ be a domain with non-negative Ricci curvature and mean curvature bounded below by $H \in \mathbb{R}$. Let $R$ be the inner radius of $\Omega$.

a) If $H > 0$ then

$$q_1(\Omega) \geq \frac{nH}{1 - (1 - RH)^n}.$$

b) If $H \geq 0$ then $q_1(\Omega) \geq 1/R$.

c) If $H = -|H| < 0$, then

$$q_1(\Omega) \geq \frac{n|H|}{(1 + R|H|)^n - 1}.$$
We already observed that a) is sharp. Observe that by Proposition 14 one has \( 1 - RH \geq 0 \), with equality only for the ball: hence \( q_1(\Omega) \geq nH \).

We remark that b) is also sharp. In fact, let \( N \) be a closed manifold and \( \Omega = N \times (0, 2R) \) with the product metric (\( \Omega \) is often called a flat cylinder). Note that the inner radius of \( \Omega \) is exactly \( R \). Now \( |\partial \Omega| = 2|N| \) and \( |\Omega| = 2R|N| \), so that \( |\partial \Omega|/|\Omega| = 1/R \). By the upper bound (4) we have \( q_1(\Omega) \leq 1/R \) and then, by b), we have equality.

We now take \( K = -1 \), so that the estimates below apply in particular to hyperbolic domains.

**Theorem 13.** Let \( \Omega^n \) be a domain with Ricci curvature bounded below by \(- (n - 1)\) and mean curvature bounded below by \( H \in \mathbb{R} \).

a) If \( H \geq 1 \) then \( q_1(\Omega) \geq \frac{n - 1}{1 - e^{-(n-1)R}} \). In particular:

\[
q_1(\Omega) > n - 1.
\]

b) If \( H \geq 0 \) then \( q_1(\Omega) \geq \frac{n - 1}{e^{(n-1)R} - 1} \).

c) If \( H = -|H| \leq 0 \) then \( q_1(\Omega) \geq \frac{n - 1}{(1 + |H|)^{n-1}(e^{(n-1)R} - 1)} \).

For the proof, we observe that \( K = -1 \) and so \( \Theta(r) = (\cosh r - H \sinh r)^{n-1} \). To prove a) we use the fact that, if \( H \geq 1 \), then \( \cosh r - H \sinh r \leq e^{-r} \), and then we carry out integration. If \( H \geq 0 \) we use the inequality \( \cosh r \leq e^r \), and if \( H = -|H| \leq 0 \) we use the inequality \( \cosh r - H \sinh r \leq (1 + |H|)e^r \).

Finally, if the Ricci curvature is bounded below by \( n - 1 \), then \( \Theta(r) = (\cos r - H \sin r)^{n-1} \), and one can get explicit estimates as well. We omit further details.

### 3.1 Proof of Corollary 3

Let \( \Omega \) be a domain with curvature bounds \((K, H)\) and let \( \Theta \) be as in (8). By Theorem 2 we have:

\[
q_1(\Omega) \geq \frac{1}{\int_0^R \Theta(r) \, dr}.
\]

Under the given assumptions on \( K \) and \( H \), there is a unique ball \( \bar{\Omega} \) in \( M_K \) with boundary of (constant) mean curvature \( H \). By its definition \( \Omega \) has also curvature bounds \((K, H)\) and by the second part of Theorem 2 we have

\[
q_1(\bar{\Omega}) = \frac{|\partial \bar{\Omega}|}{|\bar{\Omega}|} = \frac{1}{\int_0^R \Theta(r) \, dr},
\]

13
where $\bar{R}$ is the radius of $\bar{\Omega}$. Now, by Proposition 14, $\bar{R}$ is also the first zero of $\Theta$, and one has $\bar{R} \geq R$ with equality if and only if $\Omega$ is isometric to $\bar{\Omega}$. Comparison of (23) and (24) leads to the inequality $q_1(\Omega) \geq \bar{q}_1(\bar{\Omega})$ with equality iff $\Omega$ is isometric to $\bar{\Omega}$.

4 Appendix

We outline the main arguments and definitions in [11] leading to Proposition 11. All these facts are proved in Sections 2 and 3.2 of [11].

Let $N_x$ be the inner unit normal at $x \in \partial \Omega$, and consider the geodesic normal to $\partial \Omega$ and starting at $x$: $\gamma_x(t) = \exp_x(t N_x)$, where $t$ ranges in a suitable interval. The cut-radius of $x \in \partial \Omega$ is the positive number $c(x)$ defined in the following way:

- The geodesic $\gamma_x(t)$ minimizes the distance to $\partial \Omega$ if and only if $t \in [0, c(x)]$.

The map $c : \partial \Omega \to [0, \infty)$ is continuous; moreover, since $\partial \Omega$ is smooth, $c$ is positive (and $\inf_{\partial \Omega} c$ is called the injectivity radius of the normal exponential map). The cut-locus $\text{Cut}(\partial \Omega)$ is the closed subset of $\Omega$ defined by:

$$\text{Cut}(\partial \Omega) = \{ \exp_x(c(x) N_x) : x \in \partial \Omega \}$$

It is known that the cut-locus has measure zero in $\Omega$; denote by

$$\Omega_{\text{reg}} = \Omega \setminus \text{Cut}(\partial \Omega)$$

the set of regular points of $\rho$. Then, $\rho$ is $C^\infty$-smooth on $\Omega_{\text{reg}}$ and there one has $|\nabla \rho| = 1$. Consider the set

$$U = \{(r, x) \in [0, \infty) \times \partial \Omega : 0 \leq r < c(x)\}.$$

The pair $(r, x)$ gives rise to the normal coordinates of a regular point of $\Omega$. The map $\Phi(r, x) = \exp_x(r N_x)$ is a diffeomorphism $\Phi : U \to \Omega_{\text{reg}}$, and if we pull back the Riemannian volume form $d\text{vol}_g$ of $\Omega$ by $\Phi$, we can write

$$\Phi^*(d\text{vol}_g)(r, x) = \theta(r, x) dr dx,$$

where $dx$ denotes, for short, the induced volume form of $\partial \Omega$. The function $\theta$ is then the density of the Riemannian volume form in normal coordinates. Obviously $\theta$ is positive on $U$, and $\theta(0, x) = 1$ for all $x \in \partial \Omega$. So, for all integrable functions $f$ on $\Omega$:

$$\int_{\Omega} f = \int_{\Omega_{\text{reg}}} f = \int_{\partial \Omega} \int_0^{c(x)} \theta(r, x) f(r, x) dr dx$$

(25)

where we identify a regular point of $\Omega$ with its pair of normal coordinates.
The map \( \theta \) extends by continuity on \( \bar{U} \), and we will define

\[
\theta(c(x), x) \doteq \lim_{r \to c(x)} \theta(r, x).
\]

We let

\[
\Delta_{\text{reg}} \rho = \Delta(|\Omega_{\text{reg}}|),
\]

be the \textit{regular part} of the Laplacian of the distance function. It is an \( L^1 \)- function on \( \Omega_{\text{reg}} \).

In normal coordinates, one has the formula (see [4] p. 40):

\[
\Delta_{\text{reg}} \rho(r, x) = -\frac{1}{\theta} \frac{\partial \theta}{\partial r}(r, x). \tag{26}
\]

Geometrically, \( \Delta_{\text{reg}} \rho(r, x) \) is equal to \((n - 1)\)-times the mean curvature of the level set \( \{ \rho = r \} \) at the regular point \((r, x)\).

In what follows, we assume that \( \Omega \) has curvature bounds \((K, H)\); that is, its Ricci curvature is bounded below by \((n - 1)K\) and its boundary \( \partial \Omega \) has mean curvature bounded below by \( H \). Recall that \( \Theta(r) = (s'_{K}(r) - Hs_{K}(r))^{n-1} \), where \( s_{K}(r) \) has been defined in (7). Then, the classical volume estimates of Heintze and Karcher (for an independent derivation using a Laplacian comparison argument see p. 41 of [4]) imply that, at all regular points \((r, x) \in U \) one has

\[
\Delta_{\text{reg}} \rho(r, x) = -\frac{1}{\theta} \frac{\partial \theta}{\partial r}(r, x) \geq -\frac{\Theta'(r)}{\Theta(r)} \tag{27}
\]

This implies in particular that, on \( U \), one has \( \theta(r, x) \leq \Theta(r) \). As a consequence of this, and a detailed analysis of the focal points of \( \partial \Omega \), one can prove (see Theorem A of [5]):

**Proposition 14.** Assume that \( \Omega \) has curvature bounds \((K, H)\), and let \( \bar{R} \in (0, \infty] \) be the first positive zero of the function \( r \to s'_{K}(r) - Hs_{K}(r) \). Then

\[
\bar{R} \geq R,
\]

where \( R \) is the inner radius of \( \Omega \). Moreover, equality holds if and only if \( \Omega \) is a ball of radius \( R \) in the space form \( M_{K} \). Then, the function \( \Theta \) is smooth and positive on the interval \([0, R)\) and \( \Theta(R) = 0 \) only when \( \Omega \) is a geodesic ball in \( M_{K} \).

As a distribution on \( \Omega \), the Laplacian \( \Delta \rho \) splits as follows:

\[
\Delta \rho = \Delta_{\text{reg}} \rho + \Delta_{\text{cut}} \rho, \tag{28}
\]

where the regular part \( \Delta_{\text{reg}} \rho \) is \( L^1 \) and satisfies (27) and where \( \Delta_{\text{cut}} \rho \) is the distribution supported on the cut-locus and defined by:

\[
(\Delta_{\text{cut}} \rho, f) = \int_{\partial \Omega} \theta(c(x), x) f(c(x), x) \, dx.
\]
Note that $\Delta_{cut}\rho$ is a non-negative distribution: as such it can be identified with a non-negative Radon measure on $\Omega$. Hence $\Delta\rho$ is a (signed) Radon measure on $\Omega$, and can be tested on any continuous function. To verify the splitting in (28) (proved in Lemma 2.1 and Section 3.2 of [11]), we test $\Delta\rho$ on a smooth function, use normal coordinates, and integrate by parts. From the above splitting, the positivity of $\Delta_{cut}\rho$ and inequality (27) one then obtains the bound $\Delta\rho \geq -\frac{\Theta'}{\Theta} \circ \rho$ in (14).

Finally, the proof of Proposition 11 is done using integrating by parts on the level domains $\{\rho > r\}$. We remark that the arguments in [11] extend to the distance function to any submanifold of a Riemannian manifold.

Remark 15. When $\Omega$ is a ball of radius $R$ in $M_K$, one sees that, by the symmetries of $M_K$, the density $\theta(r, x)$ is independent on $x \in \partial\Omega$ and in fact one has $\theta(r, x) = \Theta(r)$ for all $r, x$; moreover $c(x) = R$ for all $x \in \partial\Omega$, and $\Theta(R) = 0$. The cut-locus reduces to a point; this is the unique focal point of $\partial\Omega$ and coincides with the center of the ball: hence $\Delta_{cut}\rho = 0$. We have equality in (27) hence also in (14) and from (25) one verifies that

$$\frac{1}{\int_0^R \Theta(r)dr} = \frac{\partial\Omega}{|\Omega|}.$$
