ABSTRACT

The aim of the study was to examine the effect of physical activity (PA) training on immune system indices while providing chemotherapy. The retrospective research was conducted at the Oncology Department of Barzilai Hospital, Israel. 62 chemotherapy treated participants aged 47–93 years met the inclusion criteria of pre and post-exercise blood tests. 17 were men (27.4%). The PA training protocol constituted of 15 minutes daily exercise. The first instructions were given by a physiotherapist at the day of chemotherapy and supervised thereafter. Training consisted of exercises to develop muscle endurance, aerobic fitness, coordination and agility in a low-intensity mode adapted to the patients’ condition. The investigative time duration ranged from 1 to 19.5 weeks; categorized as three groups. Group A: 1 to 4.5 weeks, Group B: 5 to 9 weeks and Group C: 12 to 19.5 weeks. Immune system indices: White blood cells (WBC) including lymphocytes and neutrophils counts and the Neutrophils to Lymphocytes ratio (NLR), were statistically analyzed among the three groups of participants. An upward trend was found in WBC, neutrophils and lymphocytes counts, after 5 weeks and more of exercise along with chemotherapy. Group C counts rose by 13.3%, 12% and 22% respectively. This study found no statistically significant effect of PA on NLR after the training regime among all groups. The results of the study may increase awareness of the benefits of PA as an adjunctive treatment for the disease in these patients. Further research is needed to determine the optimal length and a larger sample size at multi-center settings.

Introduction

Cancer is the second leading cause of death globally among men and women [1]. The 5-year survival rate is about 70% [2]. Regular exercising by cancer patients helps counteract the adverse effects associated with treatments [3,4]. 60-75 minutes per day of moderate-intensity activity may decrease the risk of mortality [2]. Additional benefits of physical activity (PA) during cancer treatment have shown that it reduces fatigue, caused by the disease, radiation and chemotherapy [5-7]. Moreover, exercising improves quality of life, self-esteem, increases vigor, improves balance control, body control and weight control [8-12]. As well, it revamps appetite, reduces stress, anxiety and depression, and lowers risk of falls [7,13-15]. In addition, research has shown that exercise among cancer patients improves daily functioning, preserves bone mass, and strengthens muscles function that may be impaired by chemotherapy and steroids [10,15,16]. Furthermore, it increases chances of survival, enhances the ability to cope with pain, and improves body image and mood [13,16-20]. PA reduces risk of comorbidities such as hypertension, diabetes, and cardiovascular disease [21-26].
Resistance training helps lessen the side effects associated with cancer treatment in addition to improved muscle strength and increased bone mass density [3,27,28]. Galvão et al. found that resistance training in prostate cancer patients treated with androgenic hormone reduction, raised levels of lymphocytes and neutrophils indices which indicate improved immune system response [29]. It has been suggested that training regulates and advances the immune system surveillance [30,31]. PA is a strategy postulated for the treatment of cancer through its enhancement of anti-tumor immune response. Exercise has immunostimulatory effects on the immune system in several stages of combating the tumor [30]. It is stipulated that exercise exert modulation of the immune system and may serve, as an adjunctive approach to properly activate the treatment of cancer. Neutrophil to lymphocyte ratio (NLR) score is a parameter related to the inflammatory status of an individual. It was found to indicate the risk level of breast cancer and gastrointestinal cancer. NLR index can predict the prognosis of these diseases [32-34].

The normal range of NLR is from 1 to 3 [35]. A higher-than-normal ratio has been associated with mortality from malignancies and from heart failure [36]. An association between NLR and training intensity was found among cyclists [37]. Therefore, the purpose of this study is to examine the effect of PA training - that combines muscle endurance, work on range of motions, coordination and agility - performed during chemotherapy, on patients’ immune system indices e.g. White blood cells (WBC), Neutrophils, lymphocytes and NLR scores. To explore the research hypothesis, assessment of the patients’ immune system following training exercise sessions was compared with their baseline scores. It is assumed that the average count of WBC, neutrophils and lymphocytes will increase between the beginning and the end of the PA training intervention program. Additionally, the study hypotheses that there will be an enhanced immune system response, expressed as a difference between NLR at the beginning of the intervention program and at the end of the intervention program.

Methods

This retrospective consecutive study was conducted from June 10, 2019 to November 11, 2019 at Barzilai Medical Center Oncology department in conjunction with the Physiotherapy Unit. One hundred and three participants diagnosed with various types of cancer, men and women from the south of the country, treated with chemotherapy in the oncology department were recruited to this study. Inclusion criteria were age ≥18 years and completing blood tests before and after the PA training program. Compliance was achieved with 62 participants. Exclusion criteria included missing a blood test and or training session. Participation in this PA intervention program was voluntary.

Intervention Program

Intervals of chemotherapy course administration determined the instructed training schedule. The PA intervention was implemented over three time periods, Group A: 1 to 4.5 weeks, Group B: 5 to 9 weeks and Group C: 12 to 19.5 weeks. There were no intervention programs of 10, 11 and 14-weeks duration. PA training frequency ranged between twice a week to once every two weeks. The patient exercised while in a sitting position receiving chemotherapy. Each workout lasted 15 minutes and consisted of exercises to develop muscle endurance, aerobic physical fitness, coordination, increased range of motion in the joints and agility in a low intensity adapted to the patients’ condition. The training was delivered by a qualified physical education teacher or physiotherapist from the hospital staff. Each participant was asked to perform these PA training exercises independently at home every day.

Laboratory Blood Tests

The assessments took place on 2 different dates throughout the intervention program - pre PA training and after completing the chemotherapy course, post PA intervention program. Blood tests counted immune indices: WBC, neutrophils and lymphocytes. In addition, the ratio between the numbers of neutrophils to lymphocytes was calculated.

Statistical Processing

The data processing included statistics calculations and statistical inference for testing the research hypotheses. The results of the pre and post PA intervention program served to analyze the mean of each index and T-statistics were used for comparing pre and post training exercise parameters. The results are expressed as the mean ± standard deviation.

Adherence to Ethical Rules and Privacy Protection

The study was approved by the Ethics Committee of Barzilai Medical Center. The study is retrospective which contains data collected as part of the routine care and approved by the Helsinki Committee. All participants gave written informed consent.

Results

62 patients aged 47 to 93 years old were included and had their blood drawn pre and post- chemotherapy course. The study time period ranged from one week to 19.5 weeks. The number of participants in Group A, Group B, and Group C were 27, 17 and 18, respectively. Table 1 presents the study’s demographic characteristics. The mean age was 69.9 ± 9.99 years, and gender mean age was without statistical significance between females and males (69.1±10 years and 72.5±9.6 years, respectively). The mean age was similar among Group A, Group B and Group C. In each of the
groups, most of the subjects were women. No statistically significant changes were found between the immune system indices when comparing pre and post PA intervention program (Appendix 1). In Group A, PA training intervention resulted in a decrease in all three indices: WBC, neutrophils and lymphocytes by 3%, 3% and 11% respectively (Figure 1).

Table 1: Demographic Characteristics.

|                | Group A 1 to 4.5 Weeks | Group B 5 to 9 Weeks | Group C 12 to 19.5 Weeks |
|----------------|------------------------|----------------------|--------------------------|
| **Gender**     |                        |                      |                          |
| Male (%)       | 9 (33.3%)              | 4 (23.5%)            | 4 (22.2%)                |
| Female (%)     | 18 (66.7%)             | 13 (76.5%)           | 14 (77.8%)               |
| **Age (Years)**|                       |                      |                          |
| Mean           | 69.07                  | 69.12                | 71.72                    |
| Standard Deviation | 11.15               | 9.12                 | 9.2                      |
| Minimum        | 47                     | 54                   | 54                       |
| Maximum        | 93                     | 86                   | 86                       |
| **Intervention Time (Weeks)** |                  |                      |                          |
| Mean           | 2.52                   | 6.47                 | 16.31                    |
| Standard Deviation | 1.01               | 1.23                 | 2.38                     |
| Minimum        | 1                      | 5                    | 12                       |
| Maximum        | 4.5                    | 9                    | 19.5                     |

| Post           | 2.3                           | 2.65                          | 3.12                            |

Figure 1: Trendline of mean change in immune system indices post training intervention program. The change in mean immune system indices: WBC, neutrophils and lymphocytes, post-training program presents the difference as percentage of the baseline preprogram counts. Trend lines were drawn using excel graphing program. Negative and positive change indicate decrease and increase, respectively; compared to pre PA mean counts. Group A exercised one to 4.5 weeks, Group B exercised 5 to 9 weeks and Group C exercised 12 to 19.5 weeks during their chemotherapy course.
In Group B, a similar decrease in neutrophil values was observed (2.9%), however the number of WBC and lymphocytes increased by 7.8% and 6.9%, respectively. In Group C, PA training, increased further in each of the indices: WBC, neutrophils and lymphocytes, 13.3%, 12% and 22% respectively. Figure 1 shows that as the training period extended, the indices change rose. The upward trend line manifests that a longer period of PA exercise training time could give more noticeable results. No statistically significant change was found in mean NLR following the completion of PA intervention program (Figure 2) in all three participants groups. Group A and Group C exhibited an NLR increase of 9% and 7.4% respectively, while Group B revealed 5% NLR decrease. Group B and Group C NLR means, both pre and post intervention program, are considered higher than in the general healthy population.

![Figure 2](image-url)  
Figure 2: Comparison of Neutrophils to Lymphocytes Ratio (NLR) index, pre and post exercise intervention program. Group A: 1 to 4.5 weeks, Group B: 5 to 9 weeks and Group C: 12 to 19.5 weeks. Data presented as mean ± Standard Deviation.

**Discussion**

This is the first study examining the effect of physical training on cancer patients which is performed while administering chemotherapy. The study findings reinforce previous reports showing that PA benefits patients through an ascend of the immune system at the end of the training period, especially when the intervention period exceeds 12 weeks. In addition, the longer the training period the more effect it tends to have on the immune system indices, although not statistically significant. Therefore, an extended and a more intense mode of PA may have a greater impact on the immune system parameters.

**Interpretation of WBC Neutrophils and Lymphocytes and NLR Indices**

Regular physical activity augment aspects of immune competency, thus promoting anti-cancer effect in humans was reported for lymphocytes [29,38]. Indices of WBC, neutrophils and lymphocytes were used as indicators of the immune system functional abilities. Group A exercised the shortest session and
exhibited a reduction of the immune indices. A low lymphocyte counts after exercise, was found to be a result of immune cells surveillance at the peripheral tissues [38]. All three indices increased at the end of the intervention program compared to its inception after lengthy PA and chemotherapy course in Group C. Exercise oncology field studies demonstrated that being active leads to natural killer cells mobilization into tumor lesions [38]. Thus, performing “exercise immunotherapy” mediated by these lymphocytes anti-tumor effect on neoplastic growth.

A pitfall of NLR could be due to an active hematologic disorder: Leukemia, cytotoxic chemotherapy, or granulocyte colony stimulating factor (G-CSF) may affect cell counts [39].

Therefore, the biphasic response expressed as NLR over the time of training program could be attributed to medical status of the participating patients. In addition, the low sample size could be the cause for the high variability between individuals. The study participants consisted of older adults (mean age 70 years). Aging is typically associated with decrease in immune competence which presents as lower counts [38]. Hence the challenge to elicit an enhanced immune response in these individuals who are also burdened by cancer. Aging has been reported to be associated with an increase in neutrophil counts [38]. Apparently, this could be a partial probable explanation for high NLR presented in participants of Group B and C. However, the mean age of Group A participants was similar to Groups B, C (69.7 vs 69.12, 71.72 years, respectively) thus other factors could be responsible for the differences of high baseline counts pre-exercise in groups B, C such as individuals’ inherent medical condition.

Strengths and Limitations

The fact that the training was found to be safe and non-harmful to heterogeneous population of both females and males indicates that this strategy can be used to encourage cancer patients to exercise during chemotherapy. Other intervening factors may affect the patient’s body response that were beyond the scope of this study, such as cancer type, disease status, co-existing maladies and more. Self-exercising at home was not monitored which could be a possible reason for insignificant difference between the baseline pre and “post” exercise program results.

Future Research Directions

An extended period training program and at a moderate to higher intensity should be investigated as a trend to increase the physiological effect of the immune system on the body. In addition to absolute number counts, it is pertinent to further examine the immune cells functionality to gain insight and verify their active potential exerting conjunctive cytotoxic effect on tumor cells during chemotherapy course. Future directions will explore more detailed molecular mechanism involved in the body reaction to physical exercise while chemotherapy is administered, such as specific cytokines and inflammatory factors.

Conclusion

The implication of this research may suggest that PA should be encouraged, in particular to achieve exercise induced benefit on the immune potency of the oncological population and a change in their lifestyle [40]. As a result, all cancer patients are recommended to have physical exercise as part of the standard care guidelines instructed by the ministry of health authorities. In conclusion, a long-term training period may help strengthen the immune system and thus also in dealing with the disease, as the immune system has an important role in eliminating cancer cells [30].
