ABSTRACT: In this short note, we comment on the existence of two more fermionic unitary minimal models not included in recent work by Hsieh, Nakayama, and Tachikawa. These theories are obtained by fermionizing the $\mathbb{Z}_2$ symmetry of the $m = 11$ and $m = 12$ exceptional unitary minimal models. Furthermore, we explain why these are the only missing cases.

KEYWORDS: Anomalies in Field and String Theories, Discrete Symmetries, Gauge Symmetry, Global Symmetries

ARXIV ePRINT: 2003.04278
1 Introduction

In a recent paper by Hsieh, Nakayama, and Tachikawa, it was shown that there is a fermionic unitary minimal model for each \( c = 1 - 6/(m(m + 1)) \). In particular, it is obtained by fermionizing the \( \mathbb{Z}_2 \) symmetry in the \( A \) or \( D \)-type models, and can be thought of as the fermionic partner to those two bosonic theories [1].\(^1\)

The goal of this note is two-fold. First, we point out that the \( m = 11 \) and \( m = 12 \) exceptional unitary minimal models, also called \((A_{10}, E_6)\) and \((E_6, A_{12})\), have a non-anomalous \( \mathbb{Z}_2 \) symmetry [3]. From general considerations about fermionization, we conclude that there are two additional unitary fermionic minimal models not included in the list of [1] and record their partition functions. Moreover, we use this note as an opportunity to illustrate some notation and simple ideas for upcoming work [4].

2 Minimal models

2.1 Review and classification

Minimal models are \((1+1)d\) CFTs whose Hilbert spaces are composed of a finite number of irreducible representations of the Virasoro algebra. A minimal model will generally have central charge

\[
c(p, p') = 1 - \frac{6(p - p')^2}{pp'}, \tag{2.1}
\]

\(^1\)Some of these fermionic minimal models were obtained earlier in [2], where the authors studied fermionic extensions of Virasoro minimal models.
where \( p \) and \( p' \) are positive co-prime integers and \( p > p' \geq 2 \). The potential highest weights of a minimal model at \( c(p,p') \) are given by the Kac formula

\[
    h_{r,s} = \frac{(rp - sp')^2 - (p - p')^2}{4pp'},
\]

where we use the symmetry \( h_{r,s} = h_{p'-r,p-s} \) of the Kac formula to produce a closed operator algebra of \((p - 1)(p' - 1)/2\) distinct fields.

The modular invariants of minimal models are well known to have an ADE type classification [5, 6] (see also tables 10.3 and 10.4 of [7]), which allows us to read off the highest weights/state spaces after identification with characters. More precisely, the modular invariants are in one-to-one correspondence with pairs of simply-laced Lie algebras. As a consequence of this classification, unless \( p,p' = 2,4 \), there is always more than one modular-invariant minimal model at \( c(p,p') \). That is, there are different operator algebras constructed from the same primaries and closed under OPE.

To obtain unitary minimal models, we specify to \((p,p') = (m + 1, m)\) with \( m \geq 2 \), and can take \( 1 \leq s \leq r \leq m - 1 \). For example, at \( m = 2 \) we have the \( c = 0 \) trivial CFT, at \( m = 3 \) the \( c = 1/2 \) critical Ising, and at \( m = 4 \) the \( c = 7/10 \) tricritical Ising. As promised, for \( m = 5 \) there are \( A \)-type and \( D \)-type modular invariants, which correspond to the tetracritical Ising and critical 3-state Potts model respectively. In general, for \( m \geq 5 \) there is always an \( A \)-type theory and a \( D \)-type theory, and at the special values \( m = 11, 12, 17, 18, 29, 30 \) there is a third \( E \)-type theory, corresponding to the Dynkin diagrams \( E_6, E_7, \) and \( E_8 \) for each consecutive pair. From here out we will only discuss unitary minimal models.

As mentioned in [1], there is a temptation to call the \( m = 3 \) theory a free massless Majorana fermion, and the \( m = 4 \) theory the smallest \( N = 1 \) supersymmetric minimal model. However, this is not strictly correct: the Ising model has only integral spin operators, and thus is bosonic, while the Majorana fermion has integral and half-integral spin operators, and thus is fermionic. It is similar for the \( m = 4 \) case.

### 2.2 Symmetries and \( \mathbb{Z}_2 \) orbifold

Symmetries of the operator algebra of a CFT are heavily restricted by conditions of unitarity and modular invariance. For example, \( h = 1 \) operators are not unitary in a \( c < 1 \) CFT, so one can rule out continuous internal symmetries in minimal models [8]. However, there may still be discrete symmetries.

In [3], the authors determine the maximal symmetry group of all unitary minimal models by studying the theories in the presence of twisted boundary conditions as in [9, 10]. Said differently, they determine if there are twisted partition functions which can be consistently added to the theory. Summarizing, their findings are that: \emph{All unitary minimal models have maximal symmetry group \( \mathbb{Z}_2 \), except 6. The critical and tricritical 3-Potts model have non-commuting \( \mathbb{Z}_2 \) and \( \mathbb{Z}_3 \) symmetry which combine to an \( S_3 \) symmetry, and the 4 \( E_7 \) and \( E_8 \) minimal models have no symmetry.} We note that these symmetries are the same as the automorphisms of the associated Dynkin diagrams.

As explained in [1], a theory \( T \) (put on \( S^1 \times \mathbb{R} \) for concreteness) with non-anomalous \( \mathbb{Z}_2 \) symmetry can be coupled to a background \( \mathbb{Z}_2 \)-connection. We may then consider the
untwisted Hilbert space $\mathcal{H}_{\text{Un.}}$, and the twisted Hilbert space $\mathcal{H}_{\text{Tw.}}$, depending on whether or not the background $\mathbb{Z}_2$ is trivial, i.e. if states have holonomy around $S^1$. Moreover, these Hilbert spaces may be further decomposed into states that are even or odd under the $\mathbb{Z}_2$ symmetry

$$\mathcal{H}_{T,\text{Un.}} = \mathcal{H}_{T,\text{Un.}}^+ \oplus \mathcal{H}_{T,\text{Un.}}^- \quad (2.3)$$

$$\mathcal{H}_{T,\text{Tw.}} = \mathcal{H}_{T,\text{Tw.}}^+ \oplus \mathcal{H}_{T,\text{Tw.}}^- \quad (2.4)$$

Intuitively, the gauged theory $[T/\mathbb{Z}_2]$ consists of both untwisted and twisted Hilbert spaces because it is a sum over all background connections, but it only has those states which are gauge-invariant (i.e. have a $^+$ superscript). Hence we have that

$$\mathcal{H}_{[T/\mathbb{Z}_2],\text{Un.}} = \mathcal{H}_{T,\text{Un.}}^+ \oplus \mathcal{H}_{T,\text{Tw.}}^+ \quad (2.5)$$

$$\mathcal{H}_{[T/\mathbb{Z}_2],\text{Tw.}} = \mathcal{H}_{T,\text{Un.}}^- \oplus \mathcal{H}_{T,\text{Tw.}}^- \quad (2.6)$$

More generally, when $G \neq \mathbb{Z}_2$, the splitting “even” and “odd” would be promoted to the projectors $P_\chi = \frac{1}{|G|} \sum_g \chi(g) g$ for characters $\chi \in \hat{G}$, and we recover the statements that $[T/G]$ has an emergent $\hat{G}$ symmetry, and that $[[T/G]/\hat{G}] = T$ [11] (see also [12, 13] for modern discussions).

For the unitary minimal models, it is (literally) a textbook result (see 10.7 of [7]) that the $\mathbb{Z}_2$ symmetry of any of the A-type theories can be gauged to produce the D-type theory and vice-versa.\(^2\)

3 Fermionic minimal models

3.1 Fermionization

Given a bosonic theory $T_b$ with $\mathbb{Z}_2$ symmetry, it is possible to fermionize it by a generalized Jordan-Wigner transformation, turning the $\mathbb{Z}_2$ symmetry into a $(-1)^F$ Grassmann parity. Concretely, the partition function is obtained by summing over the $\mathbb{Z}_2$ connection and coupling appropriately to a spin-structure $\rho$. In particular, on a genus $g$ surface $\Sigma$, we have

$$Z_{T_f}[\rho] = \frac{1}{2^g} \sum_{\alpha \in H^1(\Sigma, \mathbb{Z}_2)} (-1)^{\text{Arf}[\alpha+\rho]} Z_{T_b}[\alpha]. \quad (3.1)$$

The invertible topological phases that can be stacked with any fermionic theory are classified by the cobordism group $\text{Hom}(\Omega^{\text{Spin}}_d(pt), U(1)) = \mathbb{Z}_2$ [15]. The effective action for the non-trivial invertible phase is given by the low energy version of the Kitaev chain

$$e^{iS[\rho]} = (-1)^{\text{Arf}[\rho]} \quad (3.2)$$

Here the Arf-invariant $\text{Arf}[\rho]$ can be thought of as the mod 2 index of the Dirac operator. For example, on the torus, $\text{Arf}[\rho] = 0$ for the 3 “even” spin-structures (NSNS, NSR, RNS),\(^2\)

\(^2\)It is shown in [14] that the unitary minimal models do not have any ’t Hooft anomalies by general MTC considerations.
and Arf[\rho] = 1 for the 1 “odd” spin-structure (RR) due to the zero mode (see [4, 15–18]
and references within for further discussion). In practice, this means that stacking with
this theory changes the relative sign of the even and odd partition functions in a sum over
spin-structures.

Conversely, given a fermionic theory \( T_f \), it is possible to gauge the \((-1)^F\) symmetry
and produce a bosonic theory \( T_b \) with a \( \mathbb{Z}_2 \) symmetry in two distinct ways, \(^3\) by summing
over spin-structures without the Arf phase included

\[
Z_{T_b}[^{\alpha}_\rho] = \frac{1}{2^g} \sum_\rho (-1)^{\text{Arf}[\alpha+\rho]} Z_{T_f}[^{\rho}_\rho],
\]

or by first stacking \(^4\) with Arf to get

\[
Z_{T_b'}[^{\alpha}_\rho] = \frac{1}{2^g} \sum_\rho (-1)^{\text{Arf}[\alpha+\rho]+\text{Arf}[\rho]} Z_{T_f}[^{\rho}_\rho].
\]

It is not hard to convince oneself, with the formulas above, that the two distinct bosonizations are related by gauging the emergent \( \mathbb{Z}_2 \)'s, forming figure 1.

For a very concrete example, one might take the theory with \((-1)^F\) to be a free
Majorana fermion \( Z_{\text{Maj}}[^{\rho,M}_\rho] \). Stacking with Arf amounts to switching the sign of the
mass term, that is, \( Z_{\text{Maj}}[^{\rho,-M}_\rho] = (-1)^{\text{Arf}[\rho]} Z_{\text{Maj}}[^{\rho,M}_\rho] \). Bosonizing we attain the (1+1)d
Ising model [17]. Tuning to criticality, we see that the \( M = 0 \) free Majorana fermion is the
generalized Jordan-Wigner transformation of the critical Ising CFT.

General points on fermionization and gauging are discussed further from a Hilbert-
space and lattice-friendly point of view in [1], and more from the point of view of partition
functions in [4].

\(^3\)Here we assume the gravitational anomaly, \( c_L - c_R \), of \( T_f \) is divisible by 8 so that the GSO projection
produces an absolute 2d bosonic theory. See section 3 of [19] for a VOA discussion, and [4, 20] for discussions
in terms of coupling to a bulk TFT.

\(^4\)It should be stressed that it does not make sense to think of one bosonization as being more fundamental.
\( T_f \) and \( T_f \times \text{Arf} \) are simply related by an invertible topological phase inherently linked to the Grassmann
parity. See section 2 and 3.1.1 of [4] for further elaboration on this point.
3.2 Fermionic minimal models

We now briefly outline the work done by Hsieh, Nakayama, and Tachikawa in [1]. Combining the general theory above, the authors are effectively noting that the $A$ and $D$-type unitary minimal models are related by a $Z_2$ orbifold. Then, as in figure 1, there must be a fermionic theory “completing the triangle” between the two bosonic theories. In the case of the critical or tri-critical Ising, $T_b$ and $T'_b$ are not distinct theories. This will be the case for the $E_6$ models, and provides a consistency check for us later, because clearly if a theory is self-dual under $Z_2$ orbifold its fermionization must have vanishing RR-sector.

Due to the high degree of solubility of the unitary minimal models, the authors are able to explicitly tabulate the states in each of the theories and indicate which are twisted, untwisted, and even or odd (and similarly for their fermionizations). Furthermore, because the Jordan-Wigner transformation has a very concrete implementation when the theory is presented on a lattice, the authors use it to construct explicit Majorana-chain realizations of these fermionic minimal models from the bosonic spin-chains.

4 The exceptional $E_6$ cases

We now come to the main point of this note, which is to point out the following: the $E_6$ exceptional minimal models at $m = 11$ and $m = 12$ also have a non-anomalous $Z_2$ symmetry, and hence there are also fermionic minimal models associated with these. Interestingly, the $E_6$ minimal models are self-dual under $Z_2$ orbifold. This does make sense, there are no other unitary CFTs at the same central charge for them to transform into except possibly the $m = 11, 12 A$-type and $D$-type models, but clearly their $Z_2$ symmetries have already “been spent” relating to one another.

We can be more explicit and list the partition functions of such theories by borrowing the expressions from [3]. In particular, we use the twisted partition functions (equations (7.7) to (7.10) in [3]) to do simple consistency checks on the statements above in the following subsections.

Moreover, the theory of invertible topological phases and fermionization provides the tools to complete this procedure for lattice and continuum descriptions of various (1+1)d theories with non-anomalous $Z_2$ symmetry. However, it would still be interesting to obtain explicit statistical or Majorana-chain descriptions of these fermionic minimal models and possibly WZW models.

Lastly, now that all of the $Z_2$ symmetries have been addressed, these exceptional $E_6$ cases, in tandem with the work in [1], cover all possible fermionic unitary minimal models. Suppose otherwise, then there would be another fermionic model whose GSO projection is a bosonic unitary minimal model with $Z_2$ symmetry. As we have already determined and then fermionized all such bosonic $Z_2$s, this additional fermionic model must not exist.
4.1 $m = 11$ exceptional

This theory is also known as the $(A_{10}, E_6)$ unitary minimal model. The torus partition functions are\(^5\)

\[
Z_{(A_{10}, E_6)}[0, 0] = \sum_{r=1, \text{odd}}^{10} \left| \chi(r, 1) + \chi(r, 7) \right|^2 + \left| \chi(r, 4) + \chi(r, 8) \right|^2 + \left| \chi(r, 5) + \chi(r, 11) \right|^2 \tag{4.1}
\]

\[
Z_{(A_{10}, E_6)}[0, 1] = \sum_{r=1, \text{odd}}^{10} \left| \chi(r, 1) + \chi(r, 7) \right|^2 - \left| \chi(r, 4) + \chi(r, 8) \right|^2 + \left| \chi(r, 5) + \chi(r, 11) \right|^2 \tag{4.2}
\]

\[
Z_{(A_{10}, E_6)}[1, 0] = \sum_{r=1, \text{odd}}^{10} \left| \chi(r, 4) + \chi(r, 8) \right|^2 + \left\{ \left( \chi(r, 1) + \chi(r, 7) \right)^* \left( \chi(r, 5) + \chi(r, 11) \right) + \text{c.c.} \right\} \tag{4.3}
\]

\[
Z_{(A_{10}, E_6)}[1, 1] = \sum_{r=1, \text{odd}}^{10} \left| \chi(r, 4) + \chi(r, 8) \right|^2 - \left\{ \left( \chi(r, 1) + \chi(r, 7) \right)^* \left( \chi(r, 5) + \chi(r, 11) \right) + \text{c.c.} \right\} \tag{4.4}
\]

It is easy to see that the spins coming from the untwisted Hilbert spaces are bosonic. With some computational work, one may verify that they take values

\[
0, \pm 1, \pm 2, \ldots, \pm 10, \pm 13, \pm 16, \pm 19. \tag{4.5}
\]

One can also verify the untwisted partition function $Z_{(A_{10}, E_6)}[0, 0]$ is invariant under modular $S$ and $T$ transformations, and that the twisted partition functions transform into one another under modular $S$ and $T$. It’s also not hard to check that a $\mathbb{Z}_2$ orbifold returns the original partition function, or more generally that

\[
Z_{(A_{10}, E_6)}[\alpha_1, \alpha_2] = \sum_{\beta_1, \beta_2} (-1)^{\alpha_1 \beta_2 - \beta_1 \alpha_2} Z_{(A_{10}, E_6)}[\beta_1, \beta_2]. \tag{4.6}
\]

\(^5\)Throughout we use the notation

\[
Z_T[g, h] := \text{Tr}_{H_g} h^{L_0 - c/24} q^{L_0 - c/24}
\]

for bosonic partition functions. For us, $g, h \in \mathbb{Z}_2$ and $H_g$ is the $g$-twisted Hilbert space, so that $Z_T[0, h]$ can be thought of as the partition function with $h$-twist in Euclidean time. For fermionic theories, we will use the labels $NS = AP = 0$ and $R = P = 1$ for the antiperiodic and periodic sectors respectively.
The fermionic partition functions can be obtained from equation (3.1) and are

\[
Z_{f,11}[0,0] = \sum_{r=1,\text{odd}}^{10} \left| \chi(r,1) + \chi(r,7) \right|^2 + \left| \chi(r,5) + \chi(r,11) \right|^2 + \left\{ \left( \chi(r,1) + \chi(r,7) \right)^* \left( \chi(r,5) + \chi(r,11) \right) + \text{c.c.} \right\}
\]

\[
Z_{f,11}[0,1] = \sum_{r=1,\text{odd}}^{10} \left| \chi(r,1) + \chi(r,7) \right|^2 + \left| \chi(r,5) + \chi(r,11) \right|^2 - \left\{ \left( \chi(r,1) + \chi(r,7) \right)^* \left( \chi(r,5) + \chi(r,11) \right) + \text{c.c.} \right\}
\]

\[
Z_{f,11}[1,0] = \sum_{r=1,\text{odd}}^{10} 2 \left| \chi(r,4) + \chi(r,8) \right|^2
\]

\[
Z_{f,11}[1,1] = 0
\]

As promised, the RR-sector (the periodic-periodic sector) partition function is vanishing. We also note that the fermionic sectors have both integral and half-integral operators, the spins coming from the NSNS-sector (the antiperiodic-antiperiodic sector) partition function are

\[
0, \pm \frac{1}{2}, \pm \frac{2}{2}, \ldots, \pm \frac{10}{2}, \pm \frac{13}{2}, \ldots, \pm \frac{17}{2}, \pm \frac{20}{2}, \pm \frac{21}{2}, \pm \frac{25}{2}, \pm \frac{26}{2}, \pm \frac{29}{2}, \pm \frac{32}{2}, \pm \frac{35}{2}, \pm \frac{38}{2}, \pm \frac{45}{2}
\]

the ellipses mean all the spins appear in between (with half-integral step size).

4.2 \textit{m = 12} exceptional

This theory is also known as the \((E_6, A_{12})\) unitary minimal model. The torus partition functions are

\[
Z_{(E_6, A_{12})}[0,0] = \sum_{s=1,\text{odd}}^{12} \left| \chi(1,s) + \chi(7,s) \right|^2 + \left| \chi(4,s) + \chi(8,s) \right|^2 + \left| \chi(5,s) + \chi(11,s) \right|^2
\]

\[
Z_{(E_6, A_{12})}[0,1] = \sum_{s=1,\text{odd}}^{12} \left| \chi(1,s) + \chi(7,s) \right|^2 - \left| \chi(4,s) + \chi(8,s) \right|^2 + \left| \chi(5,s) + \chi(11,s) \right|^2
\]

\[
Z_{(E_6, A_{12})}[1,0] = \sum_{s=1,\text{odd}}^{12} \left| \chi(4,s) + \chi(8,s) \right|^2 + \left\{ \left( \chi(1,s) + \chi(7,s) \right)^* \left( \chi(5,s) + \chi(11,s) \right) + \text{c.c.} \right\}
\]

\[
Z_{(E_6, A_{12})}[1,1] = \sum_{s=1,\text{odd}}^{12} \left| \chi(4,s) + \chi(8,s) \right|^2 - \left\{ \left( \chi(1,s) + \chi(7,s) \right)^* \left( \chi(5,s) + \chi(11,s) \right) + \text{c.c.} \right\}
\]

As before, we can see the spins coming from the untwisted Hilbert spaces are bosonic, and that the modular \(S\) and \(T\) relationships between sectors is satisfied. The fermionic
partition functions can be obtained from equation (3.1) and are

\[
Z_{f,12}[0,0] = \sum_{s=1, \text{odd}}^{12} \left| \chi(1,s) + \chi(7,s) \right|^2 + \left| \chi(5,s) + \chi(11,s) \right|^2 \\
+ \left\{ \left( \chi(1,s) + \chi(7,s) \right) \ast \left( \chi(5,s) + \chi(11,s) \right) + \text{c.c.} \right\} \\
(4.16)
\]

\[
Z_{f,12}[0,1] = \sum_{s=1, \text{odd}}^{12} \left| \chi(1,s) + \chi(7,s) \right|^2 + \left| \chi(5,s) + \chi(11,s) \right|^2 \\
- \left\{ \left( \chi(1,s) + \chi(7,s) \right) \ast \left( \chi(5,s) + \chi(11,s) \right) + \text{c.c.} \right\} \\
(4.17)
\]

\[
Z_{f,12}[1,0] = \sum_{s=1, \text{odd}}^{12} 2 \left| \chi(4,s) + \chi(8,s) \right|^2 \\
(4.18)
\]

\[
Z_{f,12}[1,1] = 0 \\
(4.19)
\]

Acknowledgments

The author thanks Davide Gaiotto for pointing out that the exceptional minimal models should be considered and for comments on the draft.
