Abstract

Let $\mathcal{B}$ be a class of finite-dimensional Banach spaces. A $\mathcal{B}$-decomposed Banach space is a Banach space $X$ endowed with a family $\mathcal{B}_X \subset \mathcal{B}$ of subspaces of $X$ such that each $x \in X$ can be uniquely written as the sum of an unconditionally convergent series $\sum_{B \in \mathcal{B}_X} x_B$ for some $(x_B)_{B \in \mathcal{B}_X} \in \prod_{B \in \mathcal{B}_X} B$. For every $B \in \mathcal{B}_X$ let $\text{pr}_B : X \to B$ denote the coordinate projection. Let $C \subset [-1,1]$ be a closed convex set with $C \cdot C \subset C$. The $C$-decomposition constant $K_C$ of a $\mathcal{B}$-decomposed Banach space $(X, \mathcal{B}_X)$ is the smallest number $K_C$ such that for every function $\alpha : F \to C$ from a finite subset $F \subset \mathcal{B}_X$ the operator $T_\alpha = \sum_{B \in F} \alpha(B) \cdot \text{pr}_B$ has norm $\|T_\alpha\| \leq K_C$.

By $\mathcal{B}_C$ we denote the class of $\mathcal{B}$-decomposed Banach spaces with $C$-decomposition constant $K_C \leq 1$. Using the technique of Fraïssé theory, we construct a rational $\mathcal{B}$-decomposed Banach space $\mathbb{U}_C \in \mathcal{B}_C$ which contains an almost isometric copy of each $\mathcal{B}$-decomposed Banach space $X \in \mathcal{B}_C$. If $\mathcal{B}$ is the class of all 1-dimensional (resp. finite-dimensional) Banach spaces, then $\mathbb{U}_C$ is isomorphic to the complementably universal Banach space for the class of Banach spaces with an unconditional (f.d.) basis, constructed by Pełczyński (and Wojtaszczyk).

1 Introduction

A Banach space $X$ is (complementably) universal for a given class of Banach spaces if $X$ belongs to this class and every space from the class is isomorphic to a (complemented) subspace of $X$.

In 1969 Pełczyński [15] constructed a complementably universal Banach space for the class of Banach spaces with a Schauder basis. In 1971 Kadec [10] constructed a complementably universal Banach space for the class of spaces with the bounded approximation property (BAP). In the same year Pełczyński [13] showed that every Banach space with BAP is isomorphic to a complemented subspace of a Banach space with a basis. Pełczyński and Wojtaszczyk [16] constructed in 1971 a (complementably) universal Banach space for the class of spaces with a finite-dimensional decomposition. A simple construction of the Pełczyński universal space was suggested by Schechtman [17]. Applying Pełczyński’s decomposition argument [14], one immediately concludes that all three universal spaces are isomorphic. It is worth mentioning a negative result of Johnson and Szankowski [9] saying that no separable Banach space can be complementably universal for the class of all separable Banach spaces.

Lindenstrauss and Tzafriri showed in [12, l.g.5] that a Banach space with an unconditional finite-dimensional decomposition is isomorphic to a subspace of a space with an unconditional basis.

In [7] the second author constructed an isometric version of the Kadec-Pełczyński-Wojtaszczyk space. The universal Banach space from [7] was constructed using the general categorical technique of Fraïssé limits [11]. In [1,2] the authors constructed some isomorphic copies of the Pełczyński universal spaces, which are isometrically universal for the class of rational based Banach with some restrictions on the suppression or unconditional basis constants. However, as was discovered in [2], the language of based Banach spaces and base preserving morphisms does not work well for based Banach spaces with unconditional constant $> 1$.

In this paper we propose an alternative language of decomposable Banach spaces which is free of this drawback and allow us to establish nice almost universality properties of rational Banach spaces constructed in [1,2]. Our approach also allows to consider simultaneously the suppression and unconditional constants, which are just special cases of the $C$-decomposition constant $K_C$, for $C$ equal to $\{1\}$ and $\{-1, 1\}$, respectively. Also the notion of a decomposed Banach space generalizes the notions of a Banach space with unconditional base and of a Banach space with unconditional f.d. base, which was considered in [16].

For a set $X$ by $[X]^{<\omega}$ we denote the family of all finite subsets of $X$. The sets of rational and real numbers are denoted by $\mathbb{Q}$ and $\mathbb{R}$, respectively. All Banach spaces considered in this paper are separable and are over the field $\mathbb{R}$ of real numbers.

Let $(x_\alpha)_{\alpha \in A}$ be a sequence of points of a Banach space $X$, indexed by elements of a set $A$. We say that a series $\sum_{\alpha \in A} x_\alpha$ converges (more precisely, unconditionally converges) to a point $x \in X$ if for every $\varepsilon > 0$ there exists a finite subset $F \subset A$ such that $\|x - \sum_{\alpha \in B} x_\alpha\| < \varepsilon$ for any finite subset $B \subset A$ that contains $F$. 
1.1 Decomposed Banach spaces

Let $\mathcal{B}$ be a class of finite-dimensional Banach spaces such that for any linear bijective isometry $f : X \to Y$ between Banach spaces the inclusion $X \in \mathcal{B}$ implies $Y \in \mathcal{B}$. Banach spaces from the class $\mathcal{B}$ will be called basic Banach spaces. For example, for $\mathcal{B}$ we can take the class of all 1-dimensional Banach spaces (or all finite-dimensional Banach spaces).

By a $\mathcal{B}$-decomposed Banach space we understand a pair $(X, \mathcal{B}_X)$ consisting of a Banach space $X$ and a family $\mathcal{B}_X \subset \mathcal{B}$ of finite-dimensional subspaces of $X$ such that every $x \in X$ can be uniquely written as the sum of an unconditionally convergent series $\sum_{B \in \mathcal{B}_X} x_B$ consisting of points $x_B \in B$ for $B \in \mathcal{B}_X$. The convergence $x = \sum_{B \in \mathcal{B}_X} x_B$ means that for every $\varepsilon > 0$ there exists a finite subfamily $F \subset \mathcal{B}_X$ such that $\|x - \sum_{B \in \mathcal{E}} x_B\| < \varepsilon$ for any finite subfamily $\mathcal{E} \subset \mathcal{B}_X$ that contains $F$. In this case the family $\mathcal{B}_X$ is called the $\mathcal{B}$-decomposition of $X$. If the class $\mathcal{B}$ is clear from the context, then we shall speak about decomposed Banach spaces instead of $\mathcal{B}$-decomposed Banach spaces.

Fix a class $\mathcal{B}$ of finite-dimensional Banach spaces. For every $B \in \mathcal{B}_X$ let $\text{pr}_B : X \to B$ denote the coordinate projector. It assigns to each point $x \in X$ the $B$-th term $x_B$ of the unique sequence $(x_E)_{E \in \mathcal{B}_X}$ with $x = \sum_{E \in \mathcal{B}_X} x_E$. The Open Mapping Principle implies that the coordinate projector $\text{pr}_B : X \to B \subset X$ is bounded (see [4, p. 33] for more details).

For every finite subfamily $\mathcal{F} \subset \mathcal{B}_X$, consider the projector

$$\text{pr}_\mathcal{F} : X \to X, \quad x \mapsto \sum_{B \in \mathcal{F}} \text{pr}_B(x).$$

For every $x \in X$ the unconditional convergence of the series $\sum_{B \in \mathcal{B}_X} \text{pr}_B(x)$ implies the set $\{\|\text{pr}_\mathcal{F}(x)\| : \mathcal{F} \in [\mathcal{B}_X]^{<\omega}\}$ is bounded and then by the Banach-Steinhaus Uniform Boundedness Principle, the real number

$$K_s := \sup_{\mathcal{F} \in [\mathcal{B}_X]^{<\omega}} \|\text{pr}_\mathcal{F}\| \geq 1$$

is well-defined. This number will be called the suppression constant of the decomposed Banach space $(X, \mathcal{B}_X)$.

1.2 The decomposition constants of a decomposed Banach space

Let $(X, \mathcal{B}_X)$ be a decomposed Banach space with the suppression constant $K_s$.

For every function $\alpha : \mathcal{F} \to \mathbb{R}$ defined on a finite subfamily $\mathcal{F} \subset \mathcal{B}_X$, consider the operator

$$T_\alpha : X \to X, \quad T_\alpha : x \mapsto \sum_{B \in \mathcal{F}} \alpha(B) \cdot \text{pr}_B(x).$$
For a bounded subset $C \subset \mathbb{R}$ let

$$C^{<B_x} := \bigcup_{\mathcal{F} \in [B_X]^{<\omega}} C^\mathcal{F}$$

be the family of functions $\alpha : \mathcal{F} \to C$ defined on finite subfamilies $\mathcal{F}$ of $B_X$.

The number

$$K_C := \sup \{ \| T_\alpha \| : \alpha \in C^{<B_x} \}$$

is called the $C$-decomposition constant of the decomposed Banach space $(X, B_X)$. Observe that $K_{\{1\}}$ is equal to the suppression constant $K_s$ of $X$. The $\{-1, 1\}$-decompositional constant $K_{\{-1,1\}}$ is called the unconditional constant and is denoted by $K_u$ (cf. [5, §4.5], [8, 6.6]).

The decomposition constants have the following properties.

**Lemma 1** Let $(X, B_X)$ be a decomposed Banach space with suppression constant $K_s$. For any bounded subset $C \subset \mathbb{R}$ the following statements hold:

1. $K_C \geq K_s \cdot \sup_{c \in C} |c| \geq \sup_{c \in C} |c|$;
2. $K_C \leq K_s \cdot \sum_{c \in C} |c|$;
3. $K_C = K_{C \cup \{0\}}$;
4. $K_C = K_{\text{conv}(C \cup \{0\})}$;
5. $K_C \leq K_s \cdot \text{diam}(\text{conv}(C \cup \{0\})) < \infty$;
6. $K_{tC} = |t| \cdot K_C$ for any real number $t$.

**Proof**

1. To prove that $K_C \geq K_s \cdot \sup_{c \in C} |c|$, assume that this inequality does not hold. Then there exists $c \in C$ and a finite subfamily $\mathcal{F} \subset B_X$ such that $K_C < |c| \cdot \| \text{pr}_\mathcal{F} \|$. Now consider the constant function $\alpha : \mathcal{F} \to \{c\} \subset C$ and observe that $T_\alpha = c \cdot \text{pr}_\mathcal{F}$ and hence

$$K_C < |c| \cdot \| \text{pr}_\mathcal{F} \| = \| T_\alpha \| \leq K_C,$$

which is a desired contradiction completing the proof.

2. To prove that $K_C \leq K_s \cdot \sum_{c \in C} |c|$, observe that for every function $\alpha : \mathcal{F} \to C$ defined on a finite subset $\mathcal{F} \subset B_X$ we have

$$\| T_\alpha \| = \left\| \sum_{B \in \mathcal{F}} \alpha(B) \cdot \text{pr}_B \right\| = \left\| \sum_{c \in C} c \cdot \text{pr}_{\alpha^{-1}(c)} \right\| \leq \sum_{c \in C} |c| \cdot \| \text{pr}_{\alpha^{-1}(c)} \| \leq \sum_{c \in C} |c| \cdot K_s.$$

3. The inequality $K_C \leq K_{C \cup \{0\}}$ follows from the inclusion $C \subset C \cup \{0\}$; the inequality $K_{C \cup \{0\}} \leq K_C$ follows from the observation that for every function $\alpha \in (C \cup \{0\})^{<B_X}$ the operator $T_\alpha$ is equal to the operator $T_\beta$ for the function $\beta = \alpha |_{\alpha^{-1}(C)} \in C^{<B_X}$.  

© Birkhäuser
4. The inequality $K_C \leq K_{\text{conv}(\bar{C} \cup \{0\})}$ follows from the inclusion $C \subset \text{conv}(\bar{C} \cup \{0\})$.

To prove the reverse inequality, we need to prove that $\|T_\alpha\| \leq K_C$ for any function $\alpha : F \to \text{conv}(\bar{C} \cup \{0\})$ defined on a finite set $F \subset B_X$.

Let $C_0 = C \cup \{0\}$ and for every $n \in \omega$ let $C_{n+1} := \{\frac{1}{2}x + \frac{1}{2}y : x, y \in C_n\}$. It is easy to see that the union $C_\omega = \bigcup_{n \in \omega} C_n$ is a dense subset of $\text{conv}(\bar{C} \cup \{0\})$. By induction we shall show that for every $n \in \omega$ and every function $\alpha : F \to C_n$ the operator $T_\alpha$ has norm $\|T_\alpha\| \leq K_C$. For $n = 0$ this follows from the equality $K_{C_0} = K_{C \cup \{0\}} = K_C$, which was proved in the preceding statement.

Assume that for some $n \in \omega$ we proved that for every $\alpha : F \to C_n$ the operator $T_\alpha$ has norm $\|T_\alpha\| \leq K_C$. Given any function $\alpha : F \to C_{n+1}$, find two functions $\beta, \gamma : F \to C_n$ such that $\alpha(B) = \frac{1}{2}\beta(B) + \frac{1}{2}\gamma(B)$ for every $B \in F$. Then $T_\alpha = \frac{1}{2}T_\beta + \frac{1}{2}T_\gamma$ and hence

$$\|T_\alpha\| \leq \frac{1}{2}\|T_\beta\| + \frac{1}{2}\|T_\gamma\| \leq \frac{1}{2}K_C + \frac{1}{2}K_C = K_C.$$ 

Now we see that for any function $\alpha : F \to C_\omega$ the operator $T_\alpha$ has norm $\|T_\alpha\| \leq K_C$. The density of $C_\omega$ in $\text{conv}(\bar{C} \cup \{0\})$ and the continuity of the projectors $pr_B$ for $B \in F$ imply that for every function $\alpha : F \to (\bar{C} \cup \{0\})$ the operator $T_\alpha$ has norm $\|T_\alpha\| \leq \sup\{|\|T_\beta\| : \beta \in C_\omega^F\} \leq K_C$.

5. By the boundedness of the set $C$, the convex set $\text{conv}(\bar{C} \cup \{0\})$ coincides with the closed interval $[a, b]$ for the real numbers $a = \min(\bar{C} \cup \{0\})$ and $b = \max(\bar{C} \cup \{0\})$.

By the statements (4) and (2), we obtain

$$K_C = K_{[a, b]} = K_{[a, b]} \leq K_s \cdot (|a| + |b|) = K_s \cdot \text{diam}(C \cup \{0\}) < \infty.$$ 

6. For any $t \in \mathbb{R}$, the definition of the constants $K_C$ and $K_{tC}$ ensure that

$$K_{tC} = \sup \{\|T_\alpha\| : x \in (tC)^{<B_X}\} = \|T_{t\alpha}\| : x \in C^{<B_X}
= |t| \cdot \{\|T_\alpha\| : x \in C^{<B_X}\} = |t| \cdot K_C.$$ 

\[\square\]

1.3 Rational decomposed Banach spaces

A decomposed Banach space $(X, B_X)$ is a subpace of a decomposed Banach space $(Y, B_Y)$ if $X \subseteq Y$ and $B_X \subseteq B_Y$.

For a Banach space $X$ by $\| \cdot \|_X$ we denote the norm of $X$ and by

$$B_X := \{x \in X : \|x\|_X \leq 1\}$$

the closed unit ball of $X$.

A finite-dimensional decomposed Banach space $(X, B_X)$ is rational if its unit ball is a convex polyhedron spanned by finitely many points that have rational coordinates in some basis $\{e_1, \ldots, e_n\} \subset \bigcup_{B \in B_X^*} B$ of $X$. It is easy to see that any decomposed subspace of a rational finite-dimensional decomposed Banach space is rational.
A decomposed Banach space \((X, B_X)\) is rational if each finite-dimensional decomposed subspace of \((X, B_X)\) is rational.

### 1.4 Categories

Let \(\mathcal{K}\) be a category. For two objects \(A, B\) of the category \(\mathcal{K}\), by \(\mathcal{K}(A, B)\) we denote the set of all \(\mathcal{K}\)-morphisms from \(A\) to \(B\). A subcategory of \(\mathcal{K}\) is a category \(\mathcal{L}\) such that each object of \(\mathcal{L}\) is an object of \(\mathcal{K}\) and each morphism of \(\mathcal{L}\) is a morphism of \(\mathcal{K}\). Morphisms and isomorphisms of a category \(\mathcal{K}\) will be called \(\mathcal{K}\)-morphisms and \(\mathcal{K}\)-isomorphisms, respectively.

A subcategory \(\mathcal{L}\) of a category \(\mathcal{K}\) is full if each \(\mathcal{K}\)-morphism between objects of the category \(\mathcal{L}\) is an \(\mathcal{L}\)-morphism.

A category \(\mathcal{L}\) is cofinal in \(\mathcal{K}\) if for every object \(A\) of \(\mathcal{K}\) there exists an object \(B\) of \(\mathcal{L}\) such that \(\mathcal{K}(A, B)\) is nonempty. A category \(\mathcal{K}\) has the amalgamation property if for every objects \(A, B, C\) of \(\mathcal{K}\) and for every morphisms \(f \in \mathcal{K}(A, B), g \in \mathcal{K}(A, C)\) there exist an object \(D\) of \(\mathcal{K}\) and morphisms \(f' \in \mathcal{K}(B, D), g' \in \mathcal{K}(C, D)\) such that \(f' \circ f = g' \circ g\).

In this paper we shall work in the category \(\mathcal{B}\), whose objects are \(\mathcal{B}\)-decomposed Banach spaces \((X, B_X)\). For two decomposed Banach spaces \((X, B_X), (Y, B_Y)\), a morphism of category \(\mathcal{B}\) is a linear injective continuous operator \(T : X \to Y\) such that \(T(B) \in B_Y\) for every \(B \in B_X\). To shorten notation, we shall often denote decomposed Banach spaces \((X, B_X)\) by \(X\).

A morphism \(T : X \to Y\) of the category \(\mathcal{B}\) is called an isometry (or else an isometry morphism) if \(\|T(x)\|_Y = \|x\|_X\) for any \(x \in X\). By \(\mathcal{B}_{\mathcal{J}}\) we denote the category whose objects are decomposed Banach spaces and morphisms are isometry morphisms of decomposed Banach spaces. The category \(\mathcal{B}_{\mathcal{J}}\) is a subcategory of the category \(\mathcal{B}\).

By \(\mathcal{B}_{\mathcal{C}}\) (resp. \(\mathcal{B}_{\mathcal{C}}\)) we denote the full subcategory of \(\mathcal{B}\) (resp. \(\mathcal{B}_{\mathcal{J}}\)), whose objects are finite-dimensional decomposed Banach spaces, and by \(\mathcal{B}_{\mathcal{C}}\) (resp. \(\mathcal{B}_{\mathcal{C}}\)) the full subcategory of \(\mathcal{B}_{\mathcal{C}}\) (resp. \(\mathcal{B}_{\mathcal{C}}\)) whose objects are rational finite-dimensional decomposed Banach spaces.

### 1.5 \(\mathcal{B}\)-universal decomposed Banach spaces

**Definition 1** A decomposed Banach space \(U\) is defined to be \(\mathcal{B}\)-universal if \(U \in \mathcal{B}\) and each decomposed Banach space \(X \in \mathcal{B}\) is \(\mathcal{B}\)-isomorphic to a decomposed subspace of \(U\).

Applying the decomposition method of Pełczyński [15], we can prove the following uniqueness result.

**Theorem 1** Any two \(\mathcal{B}\)-universal decomposed Banach spaces are \(\mathcal{B}\)-isomorphic.

### 1.6 The categories \(\mathcal{B}_{\mathcal{C}}\) and \(\mathcal{B}_{\mathcal{C}}\)

Given a closed convex set \(C \subset [-1, 1]\), let \(\mathcal{B}_{\mathcal{C}}\) (resp. \(\mathcal{B}_{\mathcal{C}}\)) be the full subcategory of \(\mathcal{B}\) (resp. \(\mathcal{B}_{\mathcal{J}}\)) whose objects are decomposed Banach spaces with \(C\)-decomposition.
constant $K_C \leq 1$. For a decomposed Banach space $X$ we shall write $X \in \mathcal{B}_C$ if $X$ is an object of the category $\mathcal{B}_C$ (that is $X$ has $C$-decomposition constant $K_C \leq 1$).

Also consider the full subcategory $\mathcal{B}_C = \mathcal{B} \cap \mathcal{B}_C$ of the category $\mathcal{B}$ and the full subcategories $\mathcal{B}_I = \mathcal{B} \cap \mathcal{B}_I$ and $\mathcal{B}_I = \mathcal{B} \cap \mathcal{B}_I$ of the category $\mathcal{B}_I$.

From now on we assume that $C \subset [-1, 1]$ is a fixed closed convex set such that $\min C \leq 0 < \max C$ and $C \cdot C \subset C$, where $C \cdot C = \{xy : x, y \in C\}$.

2 Amalgamation

In this section we prove that the categories $\mathcal{B}_I$ and $\mathcal{B}_I$ have the amalgamation property.

**Lemma 2** (Amalgamation Lemma) Let $X, Y, Z$ be objects and $i : Z \to X$, $j : Z \to Y$ be morphisms of the category $\mathcal{B}_I$. Then there exist an object $W$ of the category $\mathcal{B}_I$ and $B_I$-morphisms $i' : X \to W$ and $j' : Y \to W$ such that the diagram

$$
\begin{array}{ccc}
Y & \xrightarrow{j'} & W \\
\downarrow{j} & & \downarrow{i'} \\
Z & \xrightarrow{i} & X
\end{array}
$$

is commutative.

Moreover, if the decomposed Banach spaces $X, Y, Z$ are rational, then so is the decomposed Banach space $W$.

**Proof** We shall prove this lemma in the special case when the isometries $i, j$ are identity inclusions; the general case is analogous but has more complicated notation. Our assumptions on $i, j$ ensure that $Z \subset X \cap Y$ and $B_Z \subset B_X \cap B_Y$, where $B_X, B_Y, B_Z \subset B$ are the decompositions of the decomposed Banach spaces $X, Y, Z$. It follows from $B_Z = B_X \cap B_Y$ that the coordinate projectors of the decompositions $B_X$ and $B_Y$ agree on the intersection $Z = X \cap Y$.

Consider the direct sum $X \oplus Y$ of the Banach spaces $X, Y$ endowed with the norm $\|(x, y)\| = \|x\|_X + \|y\|_Y$. Let $W = (X \oplus Y)/\Delta$ be the quotient by the subspace $\Delta = \{(z, -z) : z \in Z\}$.

We define linear operators $i' : X \to W$ and $j' : Y \to W$ by $i'(x) = (x, 0) + \Delta$ and $j'(y) = (0, y) + \Delta$.

Let us show $i'$ and $j'$ are isometries. Indeed, for every $x \in X$

$$
\|i'(x)\|_W = \text{dist}((x, 0), \Delta) \leq \|(x, 0)\| = \|x\|_X + \|0\|_Y = \|x\|_X.
$$

© Birkhäuser
On the other hand, for every \( z \in Z \)
\[
\| (x, 0) - (z, -z) \| = \| (x - z, z) \| = \| x - z \|_X + \| z \|_Y
\]
\[
= \| x - z \|_X + \| z \|_X \geq \| x - z + z \|_X = \| x \|_X
\]
and hence \( \| x \|_X \leq \inf_{z \in Z} \| (x, 0) - (z, -z) \| = \| i'(x) \|_W \). Therefore \( \| i'(x) \|_W = \| x \|_X \). Similarly, we can show that \( j' \) is an isometry.

We shall identify \( X \) and \( Y \) with their images \( i'(X) \) and \( j'(Y) \) in \( W \). In this case we can consider the union \( B_W := B_X \cup B_Y \) and can show that \( B_W \) is a decomposition of the (finite-dimensional) Banach space \( W \).

Let us show that the decomposed Banach space \( (W, B_W) \) has \( C \)-decomposition constant \( K_C \leq 1 \). Given any function \( \alpha : B_W \to C \), we should prove the upper bound
\[
\left\| \sum_{B \in B_W} \alpha(B) \cdot \text{pr}_B(w) \right\|_W \leq \| w \|_W
\]
for every \( w \in W \). Since 0 is a non-isolated point of the convex set \( C \), we lose no generality assuming that for every \( B \in B_W \) the number \( \alpha_B := \alpha(B) \) is not equal to zero.

Taking into account that the decomposed Banach spaces \( (X, B_X) \) and \( (Y, B_Y) \) have \( C \)-unconditional constant \( \leq 1 \), we obtain:
\[
\left\| \sum_{B \in B_W} \alpha_B w_B \right\|_W
\]
\[
= \inf \left\{ \left\| \sum_{B \in B_X \setminus B_Z} \alpha_B w_B + \sum_{B \in B_Z} \alpha_B x_B \right\|_X + \left\| \sum_{B \in B_Z} \alpha_B y_B + \sum_{B \in B_Y \setminus B_Z} \alpha_B w_B \right\|_Y : (x_B)_{B \in B_Z}, (y_B)_{B \in B_Z} \in \prod_{B \in B_Z} B, \quad \forall B \in B_Z, x_B + y_B = w_B \right\}
\]
\[
\leq \inf \left\{ \left\| \sum_{B \in B_X \setminus B_Z} w_B + \sum_{B \in B_Z} x_B \right\|_X + \left\| \sum_{B \in B_Z} y_B + \sum_{B \in B_Y \setminus B_Z} w_B \right\|_Y : (x_B)_{B \in B_Z}, (y_B)_{B \in B_Z} \in \prod_{B \in B_Z} B, \quad \forall B \in B_Z, x_B + y_B = w_B \right\}
\]
\[
= \left\| \sum_{B \in B_W} w_B \right\|_W = \| w \|_W.
\]

If the finite-dimensional based Banach spaces \( X \) and \( Y \) are rational, then so is their sum \( X \oplus Y \) and so is the quotient space \( W \) of \( X \oplus Y \).
3 $\mathfrak{B}_C$-universal decomposed Banach spaces

**Definition 2** A decomposed Banach space $X$ is called $\mathfrak{B}_C$-universal if

- each finite-dimensional decomposed subspace of $X$ is an object of the category $\mathfrak{B}_C$, and
- for any object $A$ of the category $\mathfrak{B}_C$, any $\mathfrak{B}$-morphism $f : \Lambda \to X$ defined on a decomposed subspace $\Lambda$ of $A$ can be extended to an $\mathfrak{B}$-morphism $\bar{f} : A \to X$.

We recall that $\mathfrak{B}_C$ denotes the full subcategory of $\mathfrak{B}$ whose objects are rational finite-dimensional decomposed Banach spaces with $C$-decomposition constant $K_C \leq 1$. Obviously, up to $\mathfrak{B}$-isomorphisms the category $\mathfrak{B}_C$ contains countably many objects. By Lemma 2, the category $\mathfrak{B}_C$ has the amalgamation property. We now use the concepts from [11] for constructing a “generic” sequence in $\mathfrak{B}_C$. A sequence $(X_n)_{n \in \omega}$ of objects of the category $\mathfrak{B}_C$ is called a chain if each decomposed Banach space $X_n$ is a subspace of the decomposed Banach space $X_{n+1}$.

**Definition 3** A chain $(U_n)_{n \in \omega}$ of objects of the category $\mathfrak{B}_C$ is Fraïssé if for any $n \in \omega$ and $\mathfrak{B}$-morphism $f : U_n \to Y \in \mathfrak{B}_C$ there exist $m > n$ and an $\mathfrak{B}$-morphism $g : Y \to U_m$ such that $g \circ f : U_n \to U_m$ is the identity inclusion of $U_n$ to $U_m$.

Definition 3 implies that the Fraïssé sequence $\{U_n\}_{n \in \omega}$ is cofinal in the category $\mathfrak{B}_C$ in the sense that each object $A$ of the category $\mathfrak{B}_C$ admits a $\mathfrak{B}$-morphism $A \to U_n$ for some $n \in \omega$. In this case the category $\mathfrak{B}_C$ is countably cofinal.

The name “Fraïssé sequence”, as in [11], is motivated by the model-theoretic theory of Fraïssé limits developed by Roland Fraïssé [6]. One of the results in [11] is that every countably cofinal category with amalgamation has a Fraïssé sequence. Applying this general result to our category $\mathfrak{B}_C$ we get:

**Theorem 2** [11] The category $\mathfrak{B}_C$ has a Fraïssé sequence.

From now on, we fix a Fraïssé sequence $(U_n)_{n \in \omega}$ in $\mathfrak{B}_C$. Let $\mathbb{U}_C$ be the completion of the union $\bigcup_{n \in \omega} U_n$ and $\mathcal{B}_{\mathbb{U}_C} = \bigcup_{n \in \omega} \mathcal{B}_{U_n}$. The proof of the following theorem literally repeats the proof of Theorem 4.4 in [1].

**Theorem 3** $(\mathbb{U}_C, \mathcal{B}_{\mathbb{U}_C})$ is an $\mathfrak{B}_C$-universal decomposed Banach space.

To shorten notation, the $\mathfrak{B}_C$-universal decomposed Banach space $(\mathbb{U}_C, \mathcal{B}_{\mathbb{U}_C})$ will be denoted by $\mathbb{U}_C$. The following theorem shows that such space is unique up to $\mathfrak{B}_C$-isomorphism. It can be proved by analogy with Theorem 4.5 in [1].

**Theorem 4** Any two $\mathfrak{B}_C$-universal decomposed Banach spaces $X$, $Y$ are $\mathfrak{B}$-isomorphic, which means that there exists a linear bijective isometry $X \to Y$ preserving the decompositions $\mathcal{B}_X$ and $\mathcal{B}_Y$.

**Corollary 1** Any $\mathfrak{B}_C$-universal decomposed Banach space $X$ is $\mathfrak{B}$-isomorphic to the $\mathfrak{B}_C$-universal decomposed Banach space $\mathbb{U}_C$. 

© Birkhäuser
The following universality property of the space $\mathbb{U}_C$ can be proved by analogy with Theorem 5.5 in [1].

**Theorem 5** For any rational decomposed Banach space $X \in \mathcal{B}_C$ there exists an isometry $\mathcal{B}$-morphism $f : X \to \mathbb{U}_C$.

### 4 Almost $\mathcal{B}\mathcal{J}_C$-universality

By analogy with an $\mathcal{B}\mathcal{J}_C$-universal decomposed Banach space, one can try to introduce an $\mathcal{B}\mathcal{J}_C$-universal decomposed Banach space. However such notion is vacuous as each decomposed Banach space has only countably many finite-dimensional decomposed subspaces whereas in general the category $\mathcal{B}\mathcal{J}_C$ contains continuum many pairwise non $\mathcal{B}\mathcal{J}$-isomorphic 2-dimensional decomposed Banach spaces. A “right” definition is that of an almost $\mathcal{B}\mathcal{J}_C$-universal decomposed Banach space, introduced with the help of $\varepsilon$-isometries.

For a positive real number $\varepsilon$, a linear operator $f : X \to Y$ between Banach spaces $X$ and $Y$ is called an $\varepsilon$-isometry if

$$(1 + \varepsilon)^{-1} \cdot \|x\|_X < \|f(x)\|_Y < (1 + \varepsilon) \cdot \|x\|_X$$

for every $x \in X \setminus \{0\}$. This definition implies that each $\varepsilon$-isometry is an injective linear operator.

**Definition 4** A decomposed Banach space $X$ called almost $\mathcal{B}\mathcal{J}_C$-universal if for any $\varepsilon > 0$ and finite-dimensional decomposed Banach space $A \in \mathcal{B}\mathcal{J}_C$, any $\varepsilon$-isometry $\mathcal{B}$-morphism $f : \Lambda \to X$ defined on a decomposed subspace $\Lambda$ of $A$ can be extended to an $\varepsilon$-isometry $\mathcal{B}$-morphism $\tilde{f} : A \to X$.

**Theorem 6** Any $\mathcal{B}\mathcal{J}_C$-universal decomposed Banach space $X$ is almost $\mathcal{B}\mathcal{J}_C$-universal.

**Proof** We shall use the fact, that the norm of any finite-dimensional decomposed Banach space can be approximated by a rational norm.

To prove that $X$ is almost $\mathcal{B}\mathcal{J}_C$-universal, take any $\varepsilon > 0$, any finite-dimensional decomposed Banach space $A \in \mathcal{B}\mathcal{J}_C$ and an $\varepsilon$-isometry $\mathcal{B}$-morphism $f : \Lambda \to X$ defined on a decomposed subspace $\Lambda$ of $A$. For every function $\alpha : B_A \to C$, consider the linear operator $T_\alpha : A \to A$, $T_\alpha : x \mapsto \sum_{B \in B_A} \alpha(x) \cdot \text{pr}_B(x)$. By $\|\cdot\|_A$ and $\|\cdot\|_\Lambda$ we denote the norms of the Banach spaces $A$ and $\Lambda$. The morphism $f$ determines a new norm $\|\cdot\|'_\Lambda$ on $\Lambda$, defined by $\|a\|'_\Lambda = \|f(a)\|_X$ for $a \in \Lambda$. Taking into account that the decomposed Banach space $X$ is rational with $C$-unconditional constant $K_C \leq 1$, we conclude that $\|\cdot\|'_\Lambda$ is a rational norm on $\Lambda$ such that $\|T_\alpha(a)\|'_\Lambda \leq \|a\|'_\Lambda$ for every $a \in \Lambda$ and every function $\alpha : B_A \to C$.

Since $f$ is an $\varepsilon$-isometry, $(1 + \varepsilon)^{-1} < \|a\|'_A < (1 + \varepsilon)$ for every $a \in \Lambda$ with $\|a\|_A = 1$. By the compactness of the unit sphere in $\Lambda$, there exists a positive $\delta < \varepsilon$ such that $(1 + \delta)^{-1} < \|a\|'_A < (1 + \delta)$ for every $a \in \Lambda$ with $\|a\|_A = 1$. This inequality implies $\frac{1}{1+\delta} B_A \subset B'_A \subset (1+\delta) B_A$, where $B_A = \{a \in \Lambda : \|a\|_A \leq 1\}$.
and $B'_A = \{ a \in A : \| a \|'_A \leq 1 \}$ are the closed unit balls of $A$ in the norms $\| \cdot \|_A$ and $\| \cdot \|'_A$. Choose positive real numbers $\delta', \varepsilon'$ such that $\delta < \delta' < \varepsilon' < \varepsilon$. Next, choose rational numbers $-1 \leq c \leq 0 < c' \leq 1$ such that $C \subset [c, c'] \subset \frac{1+\delta'}{1+\delta}C$ and $C \cdot [c, c'] \subset [c, c']$.

Since the norm $\| \cdot \|'_A$ is rational, there exists a basis $\{ e_1, \ldots, e_n \} \subset \bigcup B_A$ of the Banach space $A$ such that the ball $B'_A$ is a convex polyhedron whose vertices have rational coordinates in the basis $e_1, \ldots, e_n$. Such a polyhedron in $A$ will be called rational.

Let $B_A = \{ a \in A : \| x \|_A \leq 1 \}$ be the closed unit ball of the Banach space $A$. Choose a rational polyhedron $P$ in $A$ such that $P = -P$ and

$$\frac{1}{1+\varepsilon'} B_A \subset P \subset \frac{1}{1+\delta'} B_A.$$ 

Next consider the convex hull $B'_A := \text{conv}(P')$ of the set

$$P' = B'_A \cup P \cup \bigcup_{\alpha \in [c, c']^B_A} T_\alpha(P).$$

Repeating the proof of Lemma 1(4), one can show that $B'_A$ coincides with the convex hull of the set

$$B'_A \cup P \cup \bigcup_{\alpha \in [c, c']^B_A} T_\alpha(P),$$

which implies that $B'_A$ is a rational polyhedron in the decomposed Banach space $A$.

Taking into account that $[c, c'] \subset \frac{1+\delta'}{1+\delta}C$, $P \subset \frac{1+\delta'}{1+\delta} B_A$, and $A$ is a decomposed Banach space with $C$-decomposition constant $\leq 1$, we conclude that

$$P \cup \bigcup_{\alpha \in [c, c']^B_A} T_\alpha(P) \subset \frac{1}{1+\delta'} (B_A \cup \bigcup_{\alpha \in C^B_A} \frac{1+\delta'}{1+\delta} T_\alpha(B_A))$$

$$\subset \frac{1}{1+\delta'} (B_A \cup \frac{1+\delta'}{1+\delta} B_A) = \frac{1}{1+\delta} B_A. \quad (1)$$

Then

$$P' \subset B'_A \cup \frac{1}{1+\delta} B_A \subset (1 + \delta) B_A$$

and hence

$$\frac{1}{1+\varepsilon'} B_A \subset P \subset B'_A := \text{conv}(P') \subset (1 + \delta) B_A.$$ 

The convex symmetric set $B'_A := \text{conv}(P')$ determines a rational norm $\| \cdot \|'_A$ on $A$ whose unit ball coincides with $B'_A$. By $A'$ we denoted the decomposed Banach space $A$ endowed with the norm $\| \cdot \|'_A$. We claim that the decomposition $B_{A'} = B_A$ of the Banach space $A'$ has $C$-unconditional constant $K_{C'} \leq 1$. Indeed, for any function $\alpha : B_A \to C$ the inclusion $C \cdot [c, c'] \subset [c, c']$ implies
\[ T_\alpha(P') = T_\alpha(B'_A) \cup T_\alpha(P) \cup \bigcup_{\beta \in [c, c]} T_\alpha \circ T_\beta(P) \]
\[ = T_\alpha(B'_A) \cup T_\alpha(P) \cup \bigcup_{\beta \in [c, c]} T_\alpha \beta(P) \]
\[ \subset B'_A \cup \bigcup_{\beta \in [c, c]} T_\beta(P) \subset P' \]
and hence
\[ T_\alpha(B'_A) = T_\alpha(\text{conv}(P')) = \text{conv}(T_\alpha(P')) \subset \text{conv}(P') = B'_A, \]
which means that the operator \( T_\alpha : A' \to A' \) has norm \( \|T_\alpha\| \leq 1 \) and hence the decomposed Banach space \( A' \) has \( C \)-unconditional constant \( K_C \leq 1 \).

It remains to check that \( \|a\|'_A = \|a\|'_A \) for each \( a \in \Lambda \), which is equivalent to the equality \( B'_A \cap \Lambda = B'_A \). The inclusion \( B'_A \subset B'_A \cap \Lambda \) is evident. To prove the reverse inclusion \( B'_A \supset B'_A \cap \Lambda \) observe that \( P' \subset B'_A \cup \frac{1}{1+\delta} B_A \) and hence
\[ \Lambda \cap B'_A = \Lambda \cap \text{conv}(P') \subset \Lambda \cap \text{conv}\left( B'_A \cup \frac{1}{1+\delta} B_A \right) \]
\[ = \Lambda \cap \left\{ t\lambda + (1-t)a : t \in [0, 1], \lambda \in B'_A, a \in \frac{1}{1+\delta} B_A \right\} \]
\[ = \left\{ t\lambda + (1-t)a : t \in [0, 1], \lambda \in B'_A, a \in \frac{1}{1+\delta} (\Lambda \cap B_A) \right\} \]
\[ \subset \text{conv}(B'_A \cup B'_A) = B'_A. \]
The inclusions \( \frac{1}{1+\delta} B_A \subset B'_A \subset (1+\delta) B_A \) imply the strict inequality
\[ (1 + \varepsilon)^{-1} \|a\|_A < \|a\|'_A < (1 + \varepsilon) \|a\|_A \] (2)
holding for all \( a \in A \setminus \{0\} \).

Let \( A' \) and \( A' \) be the decomposed Banach spaces \( A \) and \( A \) endowed with the new rational norms \( \|\cdot\|'_A \) and \( \|\cdot\|'_A \), respectively. It is clear that \( A' \subset A' \). The definition of the norm \( \|\cdot\|'_A \) ensures that \( f : A' \to X \) is a \( \mathcal{B}_C \)-morphism. Using the \( \mathfrak{rB}_C \)-universality of \( X \), extend the \( \mathcal{B}_C \)-morphism \( f : A' \to X \) to a \( \mathcal{B}_C \)-morphism \( \tilde{f} : A' \to X \). The inequalities (2) ensure that \( \tilde{f} : A \to X \) is an \( \varepsilon \)-isometry \( \mathcal{B}_C \)-morphism from \( A \), extending the \( \varepsilon \)-isometry \( f \). This completes the proof of the almost \( \mathfrak{rB}_C \)-universality of \( X \).

**Theorem 7** Let \( X \) and \( Y \) be almost \( \mathfrak{rB}_C \)-universal decomposed Banach spaces and \( \varepsilon > 0 \). Each \( \varepsilon \)-isometry \( \mathcal{B}_C \)-morphism \( f : X_0 \to Y \) defined on a finite-dimensional decomposed subspace \( X_0 \) of the decomposed Banach space \( X \in \mathcal{B}_C \) can be extended to an \( \varepsilon \)-isometry \( \mathcal{B}_C \)-isomorphism \( \tilde{f} : X \to Y \).

Theorem 7 can be proved by analogy with Theorem 5.3 in [1].
Corollary 2 For any almost $\mathcal{B}_{\mathcal{C}}$-universal decomposed Banach spaces $X$ and $Y$ and any $\varepsilon > 0$ there exists an $\varepsilon$-isometry $\mathcal{B}$-isomorphism $f : X \to Y$.

Corollary 3 Any almost $\mathcal{B}_{\mathcal{C}}$-universal decomposed Banach space is $\mathcal{B}$-isomorphic to the $\mathcal{B}$-universal decomposed Banach space $U_C$.

Theorem 8 Let $U$ be an almost $\mathcal{B}_{\mathcal{C}}$-universal decomposed Banach space. For any $\varepsilon > 0$ and any decomposed Banach space $X \in \mathcal{B}_C$, there exists an $\varepsilon$-isometry $\mathcal{B}$-morphism $f : X \to U$.

Theorem 8 can be proved by analogy with Theorem 5.5 in [1]. Applying Theorems 6 and 8 to the $\mathcal{B}$-universal space $U_C$ we obtain its $\mathcal{B}_C$-universality.

Corollary 4 For any $\varepsilon > 0$ and any decomposed Banach space $X \in \mathcal{B}_C$, there exists an $\varepsilon$-isometry $\mathcal{B}$-morphism $f : X \to U_C$.

Corollary 5 Each almost $\mathcal{B}_{\mathcal{C}}$-universal decomposed Banach space $U$ is $\mathcal{B}$-universal and hence is $\mathcal{B}$-isomorphic to the $\mathcal{B}[0,1]$-universal space $U[0,1]$. 

Proof Given a $\mathcal{B}$-decomposed Banach space $X$, we need to prove that $X$ is $\mathcal{B}$-isomorphic to a subspace of the decomposed space $U$. Denote by $X_1$ the decomposed Banach space $X$ endowed with the equivalent norm

$$\|x\|_1 = \sup_{\alpha \in C \times X} \|T_\alpha(x)\|.$$ 

Using the inclusion $C \cdot C \subseteq C$, it is easy to check that $X_1$ has $C$-decomposition constant $\leq 1$ and hence $X_1 \in \mathcal{B}_C$. By Theorem 8, for $\varepsilon = \frac{1}{2}$ there exists an $\varepsilon$-isometry $\mathcal{B}$-morphism $f : X_1 \to U$. Then $f$ is a $\mathcal{B}$-isomorphism between $X$ and the decomposed (and hence complemented) subspace $f(X) = f(X_1)$ of the decomposed Banach space $U$.

Therefore, the decomposed Banach space $U$ is $\mathcal{B}$-universal. By Theorem 1, $U$ is $\mathcal{B}$-isomorphic to any other $\mathcal{B}$-universal decomposed Banach space, in particular, to $U[0,1]$. 

\[\square\]

5 Some special cases

In this section we survey some implications of the results obtained in the preceding sections for some special choices of the class $\mathcal{B}$ of basic Banach spaces and the convex set $C \subseteq [-1, 1]$.

5.1 $\mathcal{B}$-Decomposed Banach spaces with bounds on suppression or unconditional constants

Let us recall that for a decomposed Banach space $X$ its suppression constant $K_s$ is equal to $K_{[0,1]}$ and its unconditional constant $K_u$ is equal to $K_{[-1,1]}$. Then for every real number $K \geq 1$ the category $\mathcal{B}_{[0, \frac{1}{K}]}$ coincides with the category of decomposed
Banach spaces with suppression constant \( \leq K \) and the category \( \mathcal{B}_{[-\frac{1}{K}, \frac{1}{K}]} \) coincides with the category of decomposed Banach spaces with unconditional constant \( \leq K \).

Applying Theorems 3, 5, 6 to the convex subsets \([0, \frac{1}{K}]\) and \([\frac{-1}{K}, \frac{1}{K}]\) we get the following two corollaries.

**Corollary 6** For every real number \( K \geq 1 \), there exists a rational \( \mathcal{B} \)-decomposed Banach space \( U \) such that

1. \( U \) has suppression constant \( K_s \leq K \); 
2. for any rational \( \mathcal{B} \)-decomposed Banach space \( X \) with suppression constant \( \leq K \) there exists an isometry \( \mathcal{B} \)-morphism \( f : X \to U \); 
3. for any \( \mathcal{B} \)-decomposed Banach space \( X \) with suppression constant \( \leq K \) and any \( \varepsilon > 0 \) there exists an \( \varepsilon \)-isometry \( \mathcal{B} \)-morphism \( f : X \to U \).

**Corollary 7** For every real number \( K \geq 1 \), there exists a rational \( \mathcal{B} \)-decomposed Banach space \( U \) such that

1. \( U \) has unconditional constant \( K_u \leq K \); 
2. for any rational \( \mathcal{B} \)-decomposed Banach space \( X \) with unconditional constant \( \leq K \) there exists an isometry \( \mathcal{B} \)-morphism \( f : X \to U \); 
3. for any \( \mathcal{B} \)-decomposed Banach space \( X \) with unconditional constant \( \leq K \) and any \( \varepsilon > 0 \) there exists an \( \varepsilon \)-isometry \( \mathcal{B} \)-morphism \( f : X \to U \).

### 5.2 Universal Banach spaces with unconditional f.d. bases

If \( \mathcal{B} \) is the class of all finite-dimensional Banach spaces, then \( \mathcal{B} \)-decomposed Banach spaces are called *Banach spaces with unconditional f.d. base*. In [16] Pełczyński and Wojtaszczyk constructed a Banach space \( U_{fd} \) with unconditional f.d. base such that every Banach space with unconditional f.d. base is isomorphic to a complemented subspace of \( U_{fd} \).

Applying Corollaries 6, 7 and Theorem 1 to the class \( \mathcal{B} \) of all finite-dimensional Banach spaces, we get the following universal spaces, which are isomorphic copies of the Pełczyński-Wojtaszczyk space \( U_{fd} \).

**Corollary 8** For every real number \( K \geq 1 \), there exists a rational Banach space \( U \) with unconditional f.d. base such that

1. \( U \) has suppression constant \( K_s \leq K \); 
2. for any rational Banach space \( X \) with unconditional f.d. base and suppression constant \( \leq K \) there exists a linear isometry \( f : X \to U \) preserving the f.d. decompositions of the spaces \( X \) and \( U \); 
3. for any \( \varepsilon > 0 \) and any Banach space \( X \) with unconditional f.d. base and suppression constant \( \leq K \), there exists a linear \( \varepsilon \)-isometry \( f : X \to U \) preserving the f.d. decompositions of the spaces \( X \) and \( U \); 
4. there exists an isomorphism \( U \to U_{fd} \) preserving the decompositions of the spaces \( U \) and \( U_{fd} \).

**Corollary 9** For every real number \( K \geq 1 \), there exists a rational Banach space \( U \) with unconditional f.d. base such that
(1) \( U \) has unconditional constant \( K_u \leq K \);
(2) for any rational Banach space \( X \) with unconditional f.d. base and unconditional constant \( \leq K \) there exists a linear isometry \( f : X \to U \) preserving the f.d. decompositions of the spaces \( X \) and \( U \);
(3) for any \( \varepsilon > 0 \) and any Banach space \( X \) with unconditional f.d. base and unconditional constant \( \leq K \), there exists a linear \( \varepsilon \)-isometry \( f : X \to U \) preserving the f.d. decompositions of the spaces \( X \) and \( U \);
(4) there exists an isomorphism \( U \to \bigcup_{fd} \) preserving the decompositions of the spaces \( U \) and \( \bigcup_{fd} \).

5.3 Universal Banach spaces with unconditional bases

If \( B \) is the class of all 1-dimensional Banach spaces, then \( \mathcal{B} \)-decomposed Banach spaces can be identified with based Banach spaces, considered in [1,2]. We recall that a based Banach space is a pair \( (X, \mathcal{B}_X) \) consisting of a Banach space \( X \) and a subset \( \mathcal{B}_X \subset X \) such that every \( x \in X \) can be uniquely written as the sum of an unconditionally convergent series \( \sum_{b \in \mathcal{B}_X} x_b \cdot b \) for some sequence of real numbers \( (x_b)_{b \in \mathcal{B}_X} \). The set \( \mathcal{B}_X \) is called the unconditional basis of \( X \). Each unconditional basis \( \mathcal{B}_X \) induces a 1-dimensional decomposition \( \mathcal{B}_X := \{ \mathbb{R} \cdot b \}_{b \in \mathcal{B}_X} \subset \mathcal{B} \) of the Banach space \( X \). Conversely, for any decomposition \( \mathcal{B}_X \subset \mathcal{B} \) of a Banach space \( X \), in each 1-dimensional subspace \( B \in \mathcal{B}_X \) we can choose an element \( e_B \in B \) of norm \( \|e_B\| = 1 \) and obtain an unconditional basis \( \mathcal{B}_X := \{ e_B \}_{B \in \mathcal{B}_X} \) for \( X \). The suppression and unconditional constants of the obtained base \( \mathcal{B}_X \) coincides with the suppression and decomposition constants of the decomposition \( \mathcal{B}_X \).

A based Banach space \( (X, \mathcal{B}_X) \) is called a subspace of a based Banach space \( (Y, \mathcal{B}_Y) \) if \( X \subset Y \) and \( \mathcal{B}_X = X \cap \mathcal{B}_Y \). For two based Banach spaces \( (X, \mathcal{B}_X) \) and \( (Y, \mathcal{B}_Y) \) a linear operator \( T : X \to Y \) is called
- base-preserving if \( T|\mathcal{B}_X \) is an injective map from \( X \) to \( Y \);
- decomposition-preserving if for every \( x \in \mathcal{B}_X \) there exists a unique \( y \in \mathcal{B}_Y \) with \( T(x) \in \mathbb{R} \cdot y \).

It is clear that each base-preserving operator is decomposition-preserving.

In [1] (resp. [2]) for every real number \( K \geq 1 \) we have constructed a rational based Banach space \( (\bigcup_{K}, \mathcal{B}_{\bigcup_{K}}) \) with suppression (resp. unconditional) constant \( \leq K \) such that for any rational based Banach space \( (A, \mathcal{B}_A) \) with suppression (resp. unconditional) constant \( \leq K \), any base-preserving linear isometry \( f : A \to \bigcup_{K} \) defined on a finite-dimensional based subspace \( (A, \mathcal{B}_A) \) of \( (A, \mathcal{B}_A) \) can be extended to a base-preserving linear isometry \( f : A \to \bigcup_{K} \). The based space \( (\bigcup_{K}, \mathcal{B}_{\bigcup_{K}}) \) will be called the universal rational based Banach space with suppression (resp. unconditional) constant \( K \). In [1] (resp. [2]) it was shown that the universal space \( \bigcup_{K} \) is isomorphic to the universal Banach space \( \bigcup \) with unconditional basis, constructed by Pelczyński [15].

By [1,3] (resp. [2]), for \( K = 1 \) and any \( \varepsilon > 0 \) the universal based Banach space \( (\bigcup_{K}, \mathcal{B}_{\bigcup_{K}}) \) has the following \( \varepsilon \)-universality property: for any based Banach space \( (A, \mathcal{B}_A) \) with suppression (resp. unconditional) constant \( \leq K \), any base-preserving linear \( \varepsilon \)-isometry \( f : A \to \bigcup_{K} \) defined on a finite-dimensional
based subspace \((\Lambda, B_\Lambda)\) of \((A, B_A)\) can be extended to a base-preserving linear \(\varepsilon\)-isometry \(f : A \to \mathbb{U}_K\). By [2,3], the latter \(\varepsilon\)-extension property of \(\mathbb{U}_K\) does not hold for \(K > 1\). However, Theorem 6 implies the following weaker \(\varepsilon\)-universality property of \((\mathbb{U}_K, B_K)\), holding for every \(K > 1\).

**Corollary 10** Let \(K \geq 1\) and \((\mathbb{U}_K, B_{\mathbb{U}_K})\) be a rational universal based Banach space with suppression (resp. unconditional) constant \(K\). For every \(\varepsilon > 0\) and any based Banach space \((A, B_A)\) with suppression (resp. unconditional) constant \(\leq K\), any decomposition-preserving linear \(\varepsilon\)-isometry \(f : \Lambda \to \mathbb{U}_K\) defined on a finite-dimensional based subspace \((\Lambda, B_\Lambda)\) of \((A, B_A)\) can be extended to a decomposition-preserving linear \(\varepsilon\)-isometry \(f : A \to \mathbb{U}_K\).

This corollary follows from Theorem 6 and the observation that the universal rational based Banach space \((\mathbb{U}_K, B_{\mathbb{U}_K})\) endowed with the 1-dimensional decomposition generated by its basis \(B_{\mathbb{U}_K}\) is a rational \(tBjc\)-universal \(B\)-decomposed Banach space for \(C = \left[0, \frac{1}{K}\right]\) (resp. \(\left[-\frac{1}{K}, \frac{1}{K}\right]\)).

**6 Conclusions**

In this paper we consider the notion of a decomposed Banach space, which is more flexible comparing to a more restrictive notion of a based Banach space, exploited in [1,2]. In particular, it allowed us to introduce a true notion of an almost universal space and establish an almost universality of the \(tBjc\)-universal \(B\)-decomposed Banach spaces, constructed in [1,2].

Moreover, using the \(C\)-unconditional constants \(K_C\) allowed us to generalize the results of the papers [1–3] related to Banach spaces with some restrictions on suppression or unconditional of unconditional bases.

**Acknowledgements** The authors would like to express their sincere thanks to the (anonymous) referee of their paper [2] who advised the authors to modify the definition of a morphism between based Banach spaces, which eventually lead us to introducing the notion of a decomposed Banach space, a rational morphism between such spaces, and a correct notion of almost universality. Research of the second author was partially supported by NCN Grant DEC-2013/11/N/ST1/02963.
