Aim: To investigate the therapeutic effects of resveratrol (RSV) on periodontitis in diabetic mice and to explore the underlying mechanisms in vitro.

Methods: Experimental periodontitis was induced in db/db mice by ligature application of porphyromonas gingivalis. The mice were treated with RSV (20 mg/kg, po) daily for 4 weeks. Alveolar bone loss, proinflammatory cytokines and TLR4 expression in the gingival tissue were measured. Cultured gingival epithelial cells (GECs) were used for in vitro studies. The transcriptional activity of TLR4 downstream signaling was analyzed using Western blotting.

Results: RSV administration significantly decreased the blood glucose levels, and ameliorated alveolar bone loss in db/db mice with experimental periodontitis. RSV administration also suppressed the high levels of IL-1β, IL-6, IL-8, TNF-α, and TLR4 in gingival tissue of the mice. In the GECs incubated in high glucose medium, TLR4 expression was substantially upregulated, which was partly blocked in the presence of RSV. Lipopolysaccharides markedly increased the expression and secretion of IL-1β, IL-6, IL-8, and TNF-α in the GECs cultured in high glucose medium, which was also partly blocked in the presence of RSV. Furthermore, RSV significantly suppressed the phosphorylation of TLR4 downstream factors NF-κB p65, p38MAPK, and STAT3.

Conclusion: RSV exerts protective effects against experimental periodontitis in db/db mice via negative regulation of TLR4 signaling.

Introduction

Diabetes is a chronic metabolic disease that is characterized by hyperglycemia that results in complications such as retinopathy, microangiopathy, and nephropathy[1]. Chronic periodontitis is defined as an inflammatory disease that is caused by oral pathogenic bacteria. Strong evidence indicates that poorly controlled diabetes increases susceptibility to periodontitis, also known as diabetic periodontitis[2-4]. Patients with diabetic periodontitis exhibit greater alveolar bone loss and a poorer prognosis after routine treatments compared with patients who do not have diabetes[5]. Furthermore, some studies have revealed that an altered host immune response results in excessive inflammation and increases the severity of periodontal tissue destruction in diabetic periodontitis[6, 7].

Toll-like receptors (TLRs) are a family of pattern recognition receptors that play a major role in the recognition of pathogen-associated molecular patterns in innate immunity[6, 9]. TLR4, as a cellular receptor for bacterial lipopolysaccharide (LPS), is by far the most extensively studied member of the TLR family. LPS activates TLR4-induced downstream signaling molecules, including nuclear factor-κB (NF-κB), p38 mitogen activated protein kinase (MAPK), c-Jun N-terminal kinase (JNK), and signal transducer and activator of transcription (STAT), leading to the production of proinflammatory cytokines[10].

Some evidence indicates that the TLR4 levels are elevated in diabetes and its complications[11-13]. The increased expression of TLR4 induced by hyperglycemia results in the generation and secretion of a series of proinflammatory cytokines in adipocytes, monocytes, macrophages, and glomerular endothelial cells, among others[14, 15]. Correspondingly, related complications commonly develop[16, 17]. Recently, a higher expression...
of TLR4 has been found in gingival tissue from patients with diabetic periodontitis compared with tissue from patients who have chronic periodontitis but do not have diabetes\cite{18, 19}. In addition, TLR4 expression is markedly increased in gingival epithelial cells incubated with high glucose\cite{20}. These findings suggest that TLR4 may act as a molecular signaling to link diabetes and periodontitis.

Resveratrol (RSV) is a naturally occurring polyphenolic phytoalexin that is produced by polygonum cuspidatum, mulberry (Morus species), grapes, and red wine. It has diverse biological activities including anti-oxidation\cite{21}, anti-cancer\cite{22}, anti-inflammation\cite{23}, cardioprotection\cite{24}, and neuroprotection\cite{25}. Several reports indicate that RSV is capable of preventing and treating diabetes and its related complications\cite{26, 27}. However, the effect of RSV on diabetic periodontitis and the underlying mechanisms of action are not clear. In this study, we hypothesize that RSV may decrease local periodontal tissue inflammation and thereby alleviate alveolar bone loss by inhibiting TLR4 expression in gingival tissue during diabetic periodontitis. To confirm this hypothesis, we employed an experimental periodontitis model to detect alveolar bone loss, proinflammatory cytokines and TLR4 expression in the gingival tissue of diabetic mice with or without RSV treatment. The possible molecular mechanisms were also explored in vitro.

**Materials and methods**

**Animals and experimental design**

C57BLKS/J-db/db male mice, a model for type 2 diabetes, were obtained from the National Resource Center of Model Mice (Nanjing, China). All animal experiments were performed according to the USA National Institute of Health Guide for the Care and Use of Laboratory Animals, and the protocols were approved by the Ethics Committee for Experimental Research, Medical College of Tongji, Tongji University. These db/db mice (6 weeks old; weight 30–33 g) were kept in a room with 12 h light-dark cycles and fed a standard laboratory Altromin chow. At 8 weeks of age, db/db mice were randomly divided into 3 groups (n=10/group): untreated control group, untreated control group (DC), experimental periodontitis group (DP), experimental periodontitis with RSV group (DPR).

Porphyromonas gingivalis strain (ATCC 33277) was purchased from the American Type Culture Collection (ATCC, Manassas, USA) and grown in an anaerobic chamber with 85% N\textsubscript{2}, 10% H\textsubscript{2}, and 5% CO\textsubscript{2} at 37°C. To induce experimental periodontitis, cotton ligatures presoaked in a medium containing P. gingivalis at 100 ng/mL were wrapped around the teeth at the indicated time points, cells were treated with 25 mmol/L glucose in the high glucose condition. Gingival epithelial cell culture

Gingival tissue was isolated from 8-week-old C57BL/6 male mice (Shanghai Experimental Animal Center, Shanghai, China). The cells were isolated and cultured as described previously\cite{20}. Briefly, gingival tissue was cut into small pieces and incubated with dispase and trypsinase for 4 h to produce a single cell suspension. The cells were collected and resuspended in K-SFM medium (Sciencell, CA, USA) supplemented with 100 IU/mL penicillin and 100 µg/mL streptomycin (Gibco, USA). The medium was changed every 2 d. The cells were used at passage 3. At the indicated time points, cells were treated with 25 mmol/L glucose in the high glucose group. GECs were cultured in 5.5 mmol/L glucose in the control group.

**Quantitative real-time PCR (qRT-PCR) analysis**

Total RNA was extracted from gingival tissue samples and GECs using Trizol (Invitrogen, USA) according to the manufacturer’s protocol. Synthesis of first-strand cDNA was carried out using an RT-PCR first-strand cDNA synthesis kit (Invitrogen). Then, 1 µg cDNA was used for real-time PCR in a Bio-Rad iQ5 thermal cycler. The mRNA expression levels of the target genes were calculated via the comparative cycle threshold method using GAPDH as a control. The primer sequences used for real-time RT-PCR were as follows:

- GAPDH: forward 5’-ACAGTCAGCCGATCTTCTTT-3’, reverse 5’-GACAAGCTTCCGTTTCCTG-3’
- IL-1β: forward 5’-GCAACTGTTCCTGAACTCAACT-3’, reverse 5’-GACAAGCTTCCGTTTCCTG-3’
- TNF-α: forward 5’-GTGGAACTGGCAGAAGAGGC-3’, reverse 5’-AACTTCTCCACAACCCTCTGC-3’
- IL-8: forward 5’-GAACAGCAGTGCTGTTCTC-3’, reverse 5’-GACAAGCTTCCGTTTCCTG-3’
- IL-6: forward 5’-AGTTTGCCTTCTCTGACTGTA-3’, reverse 5’-AGACAGAGGAGCTGTTTCG-3’
- P. gingivalis 10\textsuperscript{8}/mL were treated with 25 mmol/L glucose in the high glucose group. GECs were cultured in 5.5 mmol/L glucose in the control group.

**Enzyme-linked immunosorbent assay (ELISA)**

At the third passage, GECs were incubated in 25 mmol/L glucose with or without RSV (10 µmol/L) for 24 h and were subsequently treated with LPS from P. gingivalis at 100 ng/mL with or without RSV (10 µmol/L) for 2 h. The levels of IL-1β,
IL-6, IL-8, and TNF-α in the culture media were measured using ELISA kits (R&D, USA) according to the manufacturer’s instructions.

Western blot analysis
The whole protein extraction and Western blot analyses were performed as previously described[28]. Briefly, cells were lysed on ice for 30 min with RIPA lysis buffer including protease and phosphatase inhibitors (Sigma, St Louis, MO, USA). Proteins were then extracted by centrifuging for 10 min at 10,000 × g at 4°C. Then, 10 µg of each sample protein was resuspended and electrophoresed on 8%-10% SDS-polyacrylamide gels. Fractionated proteins were transferred onto polyvinylidene difluoride membranes (Invitrogen, San Diego, CA, USA). After the membranes were blocked with 5% milk for 1 h, they were incubated with primary antibodies (Santa Cruz, Dallas, TX, USA) overnight at 4°C. The secondary antibodies (goat-anti-rabbit IgG conjugated with horseradish peroxidase, Santa Cruz, Dallas, TX, USA) were added to the membranes and incubated for 1 h at room temperature. Reactive protein bands were detected using Western Blotting Luminol Reagent (Invitrogen, San Diego, CA, USA) and exposed to X-ray film.

Statistical analysis
The SPSS 17.0 software was used to complete data processing. All data are represented as the mean±SD of three independent experiments. Statistical significance was tested by Student’s t-test and one-way ANOVA. The results were considered statistically significant when P<0.05.

Results
RSV ameliorates experimental periodontitis in db/db mice
To examine the therapeutic effects of RSV on diabetic periodontitis, we established experimental periodontitis in db/db mice with or without RSV treatment. First, we measured the fasting blood glucose levels of diabetic mice with or without RSV treatment. Although all mice had hyperglycemia, RSV-treated mice had lower blood glucose levels than did untreated mice with experimental periodontitis (DPR group vs DP group). The level of fasting blood glucose was not considerably different between mice with or without experimental periodontitis (DP group vs DC group) (Figure 1A). Conversely, in terms of alveolar bone loss, our results showed that there was a significant increase in alveolar bone loss in experimental periodontitis mice compared with control mice (DP group vs DC group). However, RSV treatment remarkably decreased alveolar bone loss associated with experimental periodontitis in db/db mice (DPR group vs DP group) (Figure 1B). It is well known that proinflammatory cytokines play an important role in periodontal tissue breakdown. We next determined whether RSV affected the expression of proinflammatory cytokines in gingival tissue. Our results showed that RSV treatment markedly decreased the mRNA expression of the proinflammatory cytokines IL-1β, IL-6, IL-8, and TNF-α in the gingival tissue of mice with experimental periodontitis (Figure 1C).

RSV reduces TLR4 expression in vivo and in vitro
qRT-PCR and Western blot were performed to detect TLR4 expression in the gingival tissue of experimental periodontitis mice treated with RSV or untreated. It was revealed that there were significant differences in the TLR4 mRNA and protein levels in the gingival tissue of diabetic periodontitis mice (DP group) and diabetic control mice (DC group). However, RSV treatment significantly reduced the expression of TLR4 in the gingival tissue of diabetic periodontitis mice (DPR group vs DP group) (Figure 2A).

In the in vitro experiment, GECs were exposed to 5.5 mmol/L glucose (NG), 25 mmol/L glucose (HG) or 25 mmol/L glucose with 10 µmol/L RSV (HG+RSV) for 24 h. It can be observed that the TLR4 mRNA and protein expressions were higher in those cells incubated in 25 mmol/L glucose (HG) compared with those cultured in 5.5 mmol/L glucose (NG). However, RSV treatment (HG+RSV) significantly reduced the expression of TLR4 induced by high glucose (Figure 2B).

RSV downregulates LPS-TLR4-induced proinflammatory cytokines gene expression and protein secretion in GECs
To evaluate whether the effects of RSV on proinflammatory cytokines were mediated by TLR4 signaling, GECs were pretreated with 25 µmol/L glucose with or without RSV (10 µmol/L) for 24 h and subsequently treated with fresh media containing P. gingivalis LPS at 100 ng/mL with or without RSV (10 µmol/L) for 2 h. The total RNA and culture supernatants were collected for real-time PCR and ELISA analysis, respectively. Our results indicated that RSV significantly suppressed the LPS-TLR4-mediated upregulation of IL-1β, IL-6, IL-8, and TNF-α mRNA expression and protein secretion under high glucose conditions (Figure 3).

RSV inhibits LPS-TLR4-induced activation of NF-κB p65, p38 MAPK, and STAT3
To understand the underlying molecular mechanisms of RSV downregulation of LPS-TLR4-induced proinflammatory cytokine expression, the activation of TLR4 downstream signaling molecules NF-κB p65, p38 MAPK, and STAT3 was determined by Western blot analysis. Cells were pre-treated with 25 mmol/L glucose with or without RSV (10 µmol/L) for 24 h and then treated with fresh media containing P. gingivalis LPS (100 ng/mL) with or without RSV (10 µmol/L) for 30 and 60 min. Our findings showed that RSV significantly inhibited the LPS-induced phosphorylation of NF-κB p65, p38 MAPK, and STAT3, which act as downstream molecules of the TLR4 signaling pathway (Figure 4).

Discussion
Diabetes is a chronic condition characterized by hyperglycemia, which exhibits an increased risk and severity to periodontal disease than that without diabetes[22, 23]. The main explanation for the occurrence of aggravating periodontitis in diabetic patients is the disrupted immuno-inflammatory homeostasis during bacteria-host interactions. RSV is a natural polypheno-
lic compound that is particularly abundant in grape skin and in mulberries and red wine. It has been reported that the oral administration of RSV reduced the blood glucose, plasma lipid and free fatty acid levels in a spontaneous diabetic model[29]. In addition, RSV attenuates the inflammatory response of the vascular wall in T2DM rats with high fat diets, and the effects are associated with down-regulation of the NF-κB signaling pathway[30]. Studies in animal models as well as in humans have revealed that the expression of proinflammatory cytokines such as IL-6 and TGF-α is elevated and sustained by hyperglycemia[31, 32]. An excessive inflammatory response has been accepted as a major contributing factor to periodontal tissue destruction and alveolar bone loss. Thus, the increased alveolar bone loss in mice with untreated diabetic periodontitis might be linked to the increased proinflammatory cytokine levels induced by periodontal pathogens and the synergistic effect of hyperglycemia. In the present study, RSV was found to decrease the level of blood glucose and ameliorate alveolar bone loss in db/db mice induced with experimental periodontitis. To further determine the therapeutic effects of RSV on diabetic periodontitis, the expression of the proinflammatory cytokines IL-1β, IL-6, IL-8, and TNF-α in gingival tissue was examined. The mice with untreated diabetic periodontitis had higher proinflammatory cytokines levels, and RSV treatment significantly reduced proinflammatory cytokine expression in db/db mice with experimental periodontitis. The findings of

Figure 1. RSV ameliorates experimental periodontitis in db/db mice. (A) DPR mice had lower blood glucose levels than did DP mice. (B) Alveolar bone loss was determined in palatal bone samples stained with 1% methylene blue and photographed at 30× magnification using a dissecting microscope. The distance between the cementoenamel junction and the alveolar crest was measured at 6 sites in each mouse (magnification, ×30). (C) Relative mRNA expression of IL-1β, IL-6, IL-8, and TNF-α in gingival tissue, normalized to GAPDH. Data are shown as the mean±SD. n=3. bP<0.05 compared with the DC group. eP<0.05 compared with the DP group.
this in vivo study suggested that RSV is potentially beneficial for treating diabetic periodontitis based on its dual roles in decreasing blood glucose levels and inhibiting proinflammatory cytokine production.

Toll-like receptors (TLRs) are pivotal innate immune receptors that induce inflammatory responses in diabetes. TLR2 and TLR4 expression and activation are increased in bone marrow-derived macrophages of non-obese diabetic (NOD) mice, correlating with increased NF-κB activation and increased pro-inflammatory cytokines. A clinical study showed that TLR2/4 mediated inflammation in monocytes was significantly correlated to the HbA1c levels in diabetic patients. Furthermore, TLR4 has been reported to link the inflammatory responses of diabetes and periodontitis. Increased expression of TLR4 was observed in the gingival epithelial tissue during hyperglycemia, and the TLR4 levels were upregulated in diabetic periodontitis subjects compared with periodontally healthy subjects with diabetes. A recent study by Yang X et al found that TLR4 expression increased in human gingival epithelial cells (HGECs) treated with high glucose in vitro. Activation of the TLR4 signaling pathway in gingival epithelial cells led to the production of several proinflammatory cytokines, including IL-6, IL-8, and TNF-α, and triggered periodontal tissue destruction. Therefore, TLR4 is an attractive target of host modulation therapy for diabetic periodontitis. Recently, some evidence has demonstrated that RSV can restore TLR4-induced inflammatory responses in monocytes. These results suggest an association between TLR4 and RSV regulatory functions in inflammation. In the current study, increased TLR4 expression in the gingival epithelium was found in diabetic periodontitis mice, whereas RSV markedly reduced TLR4 expression in db/db mice with periodontitis. The subsequent study using cultured gingival epithelial cells under high glucose conditions also supported the finding that RSV reduced TLR4 expression and downregulated LPS-TLR4-induced proinflammatory cytokine production. This study is the first to demonstrate the inhibitory effect of RSV on TLR4 expression levels and TLR4-induced proinflammatory cytokine production in the gingival tissue of diabetic periodontitis mice and in gingival epithelial cells under high glucose conditions.

It has been reported that binding of LPS to the TLR4 receptor triggers activation of the NF-κB, MAPKs, and JAK-STAT signaling pathways. To further explore the mechanisms behind the effects of RSV on diabetic periodontitis, this study focused on the TLR4 downstream signaling molecules NF-κB, p38 MAPK, and STAT3. NF-κB, known as a master transcription factor, regulates a number of proinflammatory cytokines and contributes to the development of inflammatory diseases. LPS-activated MAPK pathways, including the phosphorylation of p38 and JNK, lead to the production of several inflammatory mediators. Some studies have also demonstrated that the crosstalk between TLR4 and the JAK/STAT pathway contributes to the progression of diabetic periodontitis. In the present study, we observed that RSV had an inhibitory effect on LPS-activated NF-κB, p38 MAPK, and STAT3 pathways in gingival epithelial cells. Taken together, our results suggested that RSV suppressed inflammatory

mediator expression via the negative regulation of TLR4 and downstream signaling molecules, including NF-κB, p38 MAPK, and STAT3.

In conclusion, the current study provides evidence for the inhibitory effect of RSV on hyperglycemia and alveolar bone loss in diabetic periodontitis. These results also demonstrate that RSV can attenuate the inflammatory response in diabetic periodontitis by downregulating TLR4 expression and TLR4 downstream signaling activation. All of the aforementioned findings suggest that RSV may potentially serve as a therapeutic agent against diabetic periodontitis.
