EVOLUTION OF STATES IN A CONTINUUM MIGRATION MODEL

YURI KONDRATIEV AND YURI KOZITSKY

Abstract. The Markov evolution of states of a continuum migration model is studied. The model describes an infinite system of entities placed in \( \mathbb{R}^d \) in which the constituents appear (immigrate) with rate \( b(x) \) and disappear, also due to competition. For this model, we prove the existence of the evolution of states \( \mu_0 \to \mu_t \) such that the moments \( \mu_t(N_\Lambda^n) \), \( n \in \mathbb{N} \), of the number of entities in compact \( \Lambda \subset \mathbb{R}^d \) remain bounded for all \( t > 0 \). Under an additional condition, we prove that the density of entities and the second correlation function remain bounded globally in time.

1. Introduction

We study the Markov dynamics of an infinite system of point entities placed in \( \mathbb{R}^d \), \( d \geq 1 \), which appear (immigrate) with space-dependent rate \( b(x) \geq 0 \), and disappear. The rate of disappearance of the entity located at a given \( x \in \mathbb{R}^d \) is the sum of the intrinsic disappearance rate \( m(x) \geq 0 \) and the part related to the interaction with the existing community, which is interpreted as competition between the entities. The phase space is the set \( \Gamma \) of all subsets \( \gamma \subset \mathbb{R}^d \) such that the set \( \gamma \Lambda := \gamma \cap \Lambda \) is finite whenever \( \Lambda \subset \mathbb{R}^d \) is compact. For each such \( \Lambda \), one defines the counting map \( \Gamma \ni \gamma \to |\gamma \Lambda| := \#(\gamma \cap \Lambda) \), where the latter denotes cardinality. Thereby, one introduces the subsets \( \Gamma^{\Lambda,n} := \{ \gamma \in \Gamma : |\gamma \Lambda| = n \} \), \( n \in \mathbb{N}_0 \), and equips \( \Gamma \) with the \( \sigma \)-field generated by all such \( \Gamma^{\Lambda,n} \). This allows for considering probability measures on \( \Gamma \) as states of the system. Among them there are Poissonian states in which the entities are independently distributed over \( \mathbb{R}^d \), see [7, Chapter 2]. They may serve as reference states for studying correlations between the positions of the entities. For the nonhomogeneous Poisson measure \( \pi_\rho \) with density \( \rho : \mathbb{R}^d \to \mathbb{R}_+ := [0, +\infty) \), \( n \in \mathbb{N}_0 \), and every compact \( \Lambda \), one has

\[
\pi_\rho(\Gamma^{\Lambda,n}) = \langle \rho \rangle^n_\Lambda \exp (-\langle \rho \rangle_\Lambda) / n!, \quad \langle \rho \rangle_\Lambda := \int_\Lambda \rho(x) dx.
\] (1.1)

By (1.1) one readily gets the \( \pi_\rho \)-expected value of the number \( N_\Lambda \) of entities contained in \( \Lambda \) in the form

\[
\pi_\rho(N_\Lambda) = \int_\Gamma |\gamma \Lambda| \pi_\rho(d\gamma) = \langle \rho \rangle_\Lambda.
\] (1.2)

The case of \( \rho \equiv \kappa > 0 \) corresponds to the homogeneous Poisson measure \( \pi_\kappa \).

The counting map \( \Gamma \ni \gamma \to |\gamma| \) can also be defined for \( \Lambda = \mathbb{R}^d \). Then the set of finite configurations

\[
\Gamma_0 := \bigcup_{n \in \mathbb{N}_0} \{ \gamma \in \Gamma : |\gamma| = n \}
\] (1.3)

is measurable. In a state with the property \( \mu(\Gamma_0) = 1 \), the system is (\( \mu \)-almost surely) finite. By (1.1) one gets that either \( \pi_\rho(\Gamma_0) = 1 \) or \( \pi_\rho(\Gamma_0) = 0 \), depending on whether or not \( \rho \) is globally integrable. As \( \pi_\kappa(\Gamma_0) = 0 \), the system in state \( \pi_\kappa \) is infinite. The use of infinite configurations for modeling large finite populations is as a rule justified, see, e.g., [2], by the argument that in such a way one gets rid of the boundary and size

1991 Mathematics Subject Classification. 60J80; 92D25; 82C22.

Key words and phrases. Markov evolution, competition kernel, Poisson random field.
effects. Note that a finite system with dispersal – like the one studied in [5, 6, 8] – being placed in a noncompact habitat always disperse to fill its empty parts, and thus is developing. Infinite configurations are supposed to model developed populations. In this work, we shall consider infinite systems.

To characterize states on $\Gamma$ one employs observables – appropriate functions $F : \Gamma \to \mathbb{R}$. Their evolution is obtained from the Kolmogorov equation

$$\frac{d}{dt} F_t = LF_t, \quad F_t|_{t=0} = F_0, \quad t > 0, \quad (1.4)$$

where the generator $L$ specifies the model. The states’ evolution is then obtained from the Fokker–Planck equation

$$\frac{d}{dt} \mu_t = L^* \mu_t, \quad \mu_t|_{t=0} = \mu_0, \quad (1.5)$$

related to that in (1.4) by the duality $\mu_t(F_0) = \mu_0(F_t)$, where

$$\mu(F) := \int_{\Gamma} F(\gamma) \mu(d\gamma).$$

The model that we study in this work is specified by the following

$$(LF)(\gamma) = \sum_{x \in \gamma} \left( m(x) + \sum_{y \in \gamma \setminus x} a(x - y) \right) [F(\gamma \setminus x) - F(\gamma)] \quad (1.6)$$

$$+ \int_{\mathbb{R}^d} b(x) |F(\gamma \cup x) - F(\gamma)| \, dx.$$ 

Here $b(x)$ is the immigration rate, $m(x) \geq 0$ is the intrinsic emigration (mortality) rate, and $a \geq 0$ is the competition kernel.

**Assumption 1.1.** The competition kernel $a$ is continuous and belongs to $L^1(\mathbb{R}^d) \cap L^\infty(\mathbb{R}^d)$. The immigration and mortality rates $b$ and $m$ are continuous and bounded.

According to this we set

$$\langle a \rangle = \int_{\mathbb{R}^d} a(x) \, dx, \quad \|a\| = \sup_{x \in \mathbb{R}^d} a(x), \quad (1.7)$$

$$\|b\| = \sup_{x \in \mathbb{R}^d} b(x), \quad \|m\| = \sup_{x \in \mathbb{R}^d} m(x).$$

If one takes in (1.6) $a \equiv 0$, the model becomes exactly soluble, see subsection 2.3 below. This means that the evolution can be constructed explicitly for each initial state $\mu_0$. Assuming that $\mu_0(N^{(n)}_\Lambda) < \infty$ for all $n \in \mathbb{N}$, one can get the information about the time dependence of such moments. For $m(x) \geq m_* > 0$ for all $x \in \mathbb{R}^d$, one obtains that

$$\forall t > 0 \quad \mu_t(N^{(n)}_\Lambda) \leq C^{(n)}_\Lambda,$$

holding for each compact $\Lambda$. Otherwise, all the moments $\mu_t(N^{(n)}_\Lambda)$ are increasing ad infinitum as $t \to +\infty$. If the initial state is $\pi_{\theta_0}$, then $\mu_t = \pi_{\theta_0}$ with $\theta_t(x) = \theta_0(x) + b(x)t$ for all $x$ such that $m(x) = 0$, cf (2.22) below. In [3], for the model (1.6) with $m \equiv 0$ and a nonzero $a$ satisfying a certain (quite burdensome) condition, it was shown that $\mu_t(N_\Lambda) \leq CV(\Lambda)$ for an appropriate constant and large enough values of the Euclidean volume $V(\Lambda)$, provided the evolution of states $\mu_0 \mapsto \mu_t$ exists.

In this article, assuming that the initial state $\mu_0$ is sub-Poissonian, see Definition [2.1] below, we prove that the evolution of states $\mu_0 \mapsto \mu_t$, $t > 0$, exists (Theorem [2.4]) and is such that $\mu_t(N^{(n)}_\Lambda) \leq C^{(n)}_\Lambda$ for each $t > 0$ (Theorem [2.5] and all $m$, including the case $m \equiv 0$. Moreover, if the correlation functions $k^{(n)}_{\mu_0}$, $n \in \mathbb{N}$, of the initial state are
continuous, see subsection 2.1 below, then all $k_{\mu}^{(n)}$, $n \in \mathbb{N}$ are also continuous and such that

$$k_{\mu}^{(1)}(x) \leq C_1, \quad k_{\mu}^{(2)}(x,y)dx\,dy \leq C_2,$$

(1.8)

holding (with some positive $C_1$ and $C_2$) for all $t > 0$ and all values of the spatial variables.

The structure of the article is as follows. In Section 2, we introduce the necessary technicalities and then formulate the results: Theorems 2.4 and 2.5. Thereafter, we make a number of comments to them. In Sections 3 and 4, we present the proofs of Theorems 2.4 and 2.5 respectively.

2. Preliminaries and the Results

We begin by outlining some technical aspects of this work – a more detailed description of them can be found in [5, 6, 8, 9] and in the literature quoted therein. By $B(\mathbb{R})$ we denote the sets of all Borel subsets of $\mathbb{R}$. The configuration space $\Gamma$ is equipped with the vague topology, see [9], and thus with the corresponding Borel $\sigma$-field $B(\Gamma)$, which makes it a standard Borel space. Note that $B(\Gamma)$ is exactly the $\sigma$-field generated by the sets $\Gamma^{\Lambda,n}$, mentioned in Introduction. By $\mathcal{P}(\Gamma)$ we denote the set of all probability measures on $(\Gamma, B(\Gamma))$.

2.1. Correlation functions. Like in [6, 8], the evolution of states will be described by means of correlation functions without the direct use of (1.5). To explain the essence of this approach let us consider the set $\Theta$ of all probability measures on $(\Gamma, B(\Gamma))$.

Definition 2.1. The set of states $\mathcal{P}_{\exp}(\Gamma)$ is defined as that containing all those states $\mu \in \mathcal{P}(\Gamma)$ for which $B_{\mu}$ can be continued, as a function of $\theta$, to an exponential type entire function on $L^1(\mathbb{R}d)$. The elements of $\mathcal{P}_{\exp}(\Gamma)$ are called sub-Poissonian states.

It can be shown that a given $\mu$ belongs to $\mathcal{P}_{\exp}(\Gamma)$ if and only if its functional $B_{\mu}$ can be written down in the form

$$B_{\mu}(\theta) = \int_{\Gamma} \prod_{x \in \gamma} (1 + \theta(x)) \mu(d\gamma), \quad \theta \in \Theta.$$  

(2.1)

For the homogeneous Poisson measure $\pi_{\mu}$, it takes the form

$$B_{\pi_{\mu}}(\theta) = \exp \left( \pi \int_{\mathbb{R}d} \theta(x)dx \right).$$

Definition 2.1. The set of states $\mathcal{P}_{\exp}(\Gamma)$ is defined as that containing all those states $\mu \in \mathcal{P}(\Gamma)$ for which $B_{\mu}$ can be continued, as a function of $\theta$, to an exponential type entire function on $L^1(\mathbb{R}d)$. The elements of $\mathcal{P}_{\exp}(\Gamma)$ are called sub-Poissonian states.

It can be shown that a given $\mu$ belongs to $\mathcal{P}_{\exp}(\Gamma)$ if and only if its functional $B_{\mu}$ can be written down in the form

$$B_{\mu}(\theta) = 1 + \sum_{n=1}^{\infty} \frac{1}{n!} \int_{(\mathbb{R}d)^n} k_{\mu}^{(n)}(x_1, \ldots, x_n) \theta(x_1) \cdots \theta(x_n) dx_1 \cdots dx_n,$$

(2.2)

where $k_{\mu}^{(n)}$ is the $n$-th order correlation function of $\mu$. It is a symmetric element of $L^\infty((\mathbb{R}d)^n)$ for which

$$\|k_{\mu}^{(n)}\|_{L^\infty((\mathbb{R}d)^n)} \leq C \exp(\vartheta n), \quad n \in \mathbb{N}_0,$$

(2.3)

with some $C > 0$ and $\vartheta \in \mathbb{R}$. Note that $k_{\pi_{\mu}}^{(n)}(x_1, \ldots, x_n) = \pi^\mu$. Note also that (2.2) resembles the Taylor expansion of the characteristic function of a probability measure. In view of this, $k_{\mu}^{(n)}$ are also called (factorial) moment functions, cf e.g., [12].

Recall that $\Gamma_0$ – the set of all finite $\gamma \in \Gamma$ defined in (1.3) – is an element of $B(\Gamma)$. A function $G : \Gamma_0 \rightarrow \mathbb{R}$ is $B(\Gamma)/B(\mathbb{R})$-measurable, see [6], if and only if, for each $n \in \mathbb{N}$, there exists a symmetric Borel function $G^{(n)} : (\mathbb{R}d)^n \rightarrow \mathbb{R}$ such that

$$G(\eta) = G(\eta) = G^{(n)}(x_1, \ldots, x_n), \quad \text{for } \eta = \{x_1, \ldots, x_n\}.$$  

(2.4)
Thereby, one can transform the action of $B$ on $F$, see (1.5), to the action of $L^\Lambda$ on $k_\mu$ according to the rule

$$\int_{\Gamma_0} (LF_\theta)(\gamma) \mu(d\gamma) = \int_{\Gamma_0} (L^\Lambda k_\mu)(\eta) e(\eta; \theta) \mu(d\eta).$$

(2.7)

This will allow us to pass from (1.5) to the corresponding Cauchy problem for the correlation functions

$$\frac{d}{dt} k_t = L^\Lambda k_t, \quad k_t|_{t=0} = k_\mu_0.$$ 

(2.8)

By (2.7) the action of $L^\Lambda$ is

$$(L^\Lambda k)(\eta) = (L^\Lambda k)(\eta) + \sum_{x \in \eta} b(x) k(\eta \setminus x),$$

(2.9)

where

$$(L^\Lambda k)(\eta) = -E(\eta) k(\eta) - \int_{\mathbb{R}^d} \left( \sum_{y \in \eta} a(x - y) \right) k(\eta \cup x) dx,$$

(2.10)

and

$$E(\eta) = \sum_{x \in \eta} m(x) + \sum_{x \in \eta} \sum_{y \in \eta|x} a(x - y).$$

(2.11)

In the next subsection, we introduce the spaces where we are going to define (2.8).

2.2. The Banach spaces. By (2.2) and (2.6), it follows that $\mu \in \mathcal{P}_{\exp}(\Gamma)$ implies

$$|k_\mu(\eta)| \leq C \exp(\vartheta|\eta|),$$

holding for $\lambda$-almost all $\eta \in \Gamma_0$, some $C > 0$, and $\vartheta \in \mathbb{R}$. In view of this, we set

$$\mathcal{K}_\vartheta := \{ k : \Gamma_0 \to \mathbb{R} : \|k\|_\vartheta < \infty \},$$

(2.12)

where

$$\|k\|_\vartheta = \operatorname{ess} \sup_{\eta \in \Gamma_0} \{ |k_\mu(\eta)| \exp(-\vartheta|\eta|) \}.$$ 

(2.13)
Clearly, (2.12) and (2.13) define a Banach space. In the following, we use the ascending scale of such spaces $K_\vartheta, \vartheta \in \mathbb{R}$, with the property
\[ K_\vartheta \hookrightarrow K_{\vartheta'}, \quad \vartheta < \vartheta', \tag{2.14} \]
where $\hookrightarrow$ denotes continuous embedding.

For $G \in B_{bs}(\Gamma_0)$, we set
\[ (KG)(\gamma) = \sum_{\eta \in \gamma} G(\eta), \tag{2.15} \]
where $\sum$ indicates that the summation is taken over all finite subsets. It satisfies, see Definition 2.2,
\[ |(KG)(\gamma)| \leq (1 + |\gamma \cap \Lambda(G)|)^N(G). \]
The latter means that $\mu(KG) < \infty$ for each $\mu \in \mathcal{P}_{exp}(\Gamma)$. By (2.6) this yields
\[ \langle \langle G, k_\mu \rangle \rangle := \int_{\Gamma_0} G(\eta) k_\mu(\eta) \lambda(d\eta) = \mu(KG) < \infty. \tag{2.16} \]

Set, cf (2.17),
\[ K^*_{\vartheta} = \{ k \in K_\vartheta : \langle \langle G, k \rangle \rangle \geq 0 \text{ for all } G \in B_{bs}^*(\Gamma_0) \}, \tag{2.19} \]
which is a subset of the cone
\[ K^*_\vartheta = \{ k \in K_\vartheta : k(\eta) \geq 0 \text{ for } \lambda - \text{almost all } \eta \in \Gamma_0 \}. \tag{2.20} \]

By Proposition 2.3 it follows that each $k \in K^*_\vartheta$ such that $k(\emptyset) = 1$ is the correlation function of a unique state $\mu \in \mathcal{P}_{exp}(\Gamma)$ for which $k$ is the correlation function.

Set, cf (2.17),
\[ K^* = \bigcup_{\vartheta \in \mathbb{R}} K^*_\vartheta, \quad K^* = \bigcup_{\vartheta \in \mathbb{R}} K^*_\vartheta. \tag{2.20} \]

As a sum of Banach spaces, the linear space $K$ is equipped with the corresponding inductive topology that turns it into a locally convex space.

### 2.3. Without competition

The version of (1.6) with $a \equiv 0$ is known as the Surgailis model, see [14] and the discussion in [3]. This model is exactly soluble, which means that the solution of (2.8) can be written down explicitly in the following form
\[ k_t(\eta) = \sum_{\xi \subset \eta} e(\xi; \phi_t)e(\eta \setminus \xi; \psi_t) k_{\mu_0}(\eta \setminus \xi), \tag{2.21} \]

where
\[ \psi_t(x) = e^{-m(x)t}, \quad e(\xi; \phi) = \prod_{x \in \xi} \phi(x), \tag{2.22} \]
\[ \phi_t(x) = \begin{cases} \left(1 - e^{-m(x)t}\right) \frac{b(x)}{m(x)} & \text{for } m(x) > 0, \\ b(x)t & \text{for } m(x) = 0. \end{cases} \]
The corresponding state $\mu_t$ has the Bogoliubov functional

$$B_{\mu_t}(\theta) = \exp \left( \int_{\mathbb{R}^d} \theta(x) \phi_t(x) dx \right) B_{\mu_0}(\theta \psi_t),$$

(2.23)

which one obtains from (2.6) and (2.21). This formula can be used to extend the evolution $\mu_0 \mapsto \mu_t$ to all $\mu_0 \in \mathcal{P}(\Gamma)$. Indeed, for each $t > 0$ and $\theta \in \Theta$, cf. (2.1), we have that $\theta \psi_t \in \Theta$, and hence $B_{\mu_0}(\theta \psi_t)$ is the Bogoliubov functional of a certain state. The same is true for the left-hand side of (2.23), and the state $\mu_t$ can be considered as a weak solution of the corresponding Fokker-Planck equation (1.5).

If the initial state is Poissonian with density $\varrho_0(x)$, by (2.23) the state $\mu_t$ is also Poissonian with the density

$$\varrho_t(x) = \psi_t(x) \varrho_0(x) + \phi_t(x).$$

If $m(x) \geq m_\ast > 0$ for some $m_\ast$ and all $x \in \mathbb{R}^d$, then the solution in (2.21) lies in $\mathcal{K}_{\varrho_\ast}$ for all $t > 0$. Here

$$\varrho_\ast = \max \{ \varrho_0; \log(||b||/m_\ast) \}.$$

(2.24)

Otherwise, the solution in (2.21) is unboundedly increasing in $t$. If, for some compact $\Lambda$, $m(x) = 0$ for $x \in \Lambda$, then by (2.21) and (2.22) we get

$$k_t^{(1)}(x) = k_t^{(1)}(x) + b(x)t, \quad x \in \Lambda,$$

that by (1.2), (2.15) and (2.16) yields

$$\mu_t(N_\Lambda) = \int_{\Gamma} |\gamma_\Lambda| \mu_t(d\gamma) = \int_{\Gamma} \left( \sum_{x \in \gamma} I_\Lambda(x) \right) \mu_t(d\gamma)$$

(2.25)

$$= \int_{\Gamma} (KI_\Lambda)(\gamma) \mu_t(d\gamma) = \int_{\Lambda} k_t^{(1)}(x) dx = \mu_0(N_\Lambda) + t \int_{\Lambda} b(x) dx,$$

where $I_\Lambda$ is the indicator of $\Lambda$. Then $\mu_t(N_\Lambda) \to +\infty$ as $t \to +\infty$ if $b$ is not identically zero on $\Lambda$.

2.4. **The statements.** For each $\vartheta \in \mathbb{R}$ and $\vartheta' > \vartheta$, the expressions in (2.9) and (2.10) can be used to define the corresponding bounded linear operators $L^\Lambda_{\vartheta'; \vartheta}$ acting from $\mathcal{K}_{\vartheta'}$ to $\mathcal{K}_{\vartheta}$. Their operator norms can be estimated similarly as in [8, eqs. (3.11), (3.13)], which yields, cf. (1.7),

$$\|L^\Lambda_{\vartheta'; \vartheta}\| \leq \frac{4\|a\|}{e^2(\vartheta' - \vartheta)^2} + \frac{\|b\|e^{-\vartheta} + \|m\| + (a)e^{\vartheta'}}{e(\vartheta' - \vartheta)}. \quad (2.26)$$

By means of the collection $\{L^\Lambda_{\vartheta'; \vartheta}\}$ with all $\vartheta \in \mathbb{R}$ and $\vartheta' > \vartheta$ we introduce a continuous linear operator acting on $\mathcal{K}$, denoted also as $L^\Lambda$, and thus define the corresponding Cauchy problem (2.8) in this space. By its (global in time) solution we will mean a continuously differentiable function $[0, +\infty) \ni t \mapsto k_t \in \mathcal{K}$ such that both equalities in (2.8) hold. Our results are given in the following statements, both based on Assumption 1.1.

**Theorem 2.4** (Existence of evolution). For each $\mu_0 \in \mathcal{P}_{\exp}(\Gamma)$, the problem in (2.8) with $L^\Lambda : \mathcal{K} \to \mathcal{K}$ as in (2.9), (2.10) and (2.26) has a unique solution which lies in $\mathcal{K}^*$ and is such that $k_t(0) = 1$ for all $t > 0$. Therefore, for each $t > 0$, there exists a unique state $\mu_t \in \mathcal{P}_{\exp}(\Gamma)$ such that $k_t = k_{\mu_t}$. Moreover, for all $t > 0$, the following holds

$$0 \leq k_t(\eta) \leq \sum_{\xi \in \eta} e^{(\xi; \phi_t) + (\eta \setminus \xi; \psi_t)} k_{\mu_0}(\eta \setminus \xi). \quad (2.27)$$

\footnote{This state is an independent thinning of $\mu_0$.}
where \( \phi_t \) and \( \psi_t \) are as in (2.22). If the intrinsic mortality rate satisfies \( m(x) \geq m_* > 0 \) for all \( x \in \mathbb{R}^d \), then for all \( t > 0 \) the solution \( k_t \) lies in \( K_{\vartheta_*} \) with \( \vartheta_* \) is given in (2.24).

Theorem 2.5 (Global boundedness). The states \( \mu_t \) mentioned in Theorem 2.4 have the property: for every \( n \in \mathbb{N} \) and compact \( \Lambda \subset \mathbb{R}^d \), the following holds

\[
\forall t > 0 \quad \mu_t(N^{n}_\Lambda) \leq C^{(n)}_{\Lambda}, \tag{2.28}
\]

with some \( C^{(n)}_{\Lambda} > 0 \). If \( \mu_0 \) is such that each \( k^{(n)}_{\mu_0} \) is a continuous function, then so is \( k^{(n)}_{\mu_t} \) for all \( n \in \mathbb{N} \) and \( t > 0 \). Moreover, \( k^{(1)}_{\mu_t} \) and \( k^{(2)}_{\mu_t} \) have the properties as in (1.8).

2.5. Comments and comparison. By (2.26) it follows that the global in time boundedness in the Surgailis model is possible only if \( m(x) \geq m_* > 0 \) for all \( x \in \mathbb{R}^d \). As follows from our Theorem 2.5 adding competition to the Surgailis model with the zero intrinsic mortality rate yields the global in time boundedness. In this case, the competition rate \( a(0) \) appears to be an effective mortality, see the proof of Theorem 2.5 and (4.19) in particular. Note also that the global boundedness as in Theorem 2.5 does not mean that the evolution \( k_{\mu_0} \rightarrow k_t \) holds in one and the same \( \mathcal{K}_\vartheta \) with sufficiently large \( \vartheta \). It does if \( m(x) \geq m_* > 0 \). Since Theorem 2.4 covers also the case \( a \equiv 0 \), the solution in (2.21) is unique in the same sense. A partial result on the global boundedness in the model discussed here was obtained in [3, Theorem 1]. Therein, under quite a strong condition imposed on the competition kernel \( a \) (which, in particular, implies that it has infinite range), and under the assumption that the evolution of states \( \mu_0 \rightarrow \mu_t \) exists, there was proved the fact which in the present notations can be formulated as \( \mu_t(N_{\Lambda}) = C_\Lambda \).

3. THE EXISTENCE OF THE EVOLUTION OF STATES

We follow the line of arguments used in proving Theorem 3.3 in [8] and perform the following three steps:

(i) Defining the Cauchy problem (2.8) with \( k_{\mu_0} \in K_{\vartheta_0} \) in a given Banach space \( \mathcal{K}_\vartheta \) with \( \vartheta > \vartheta_0 \), see (2.12) and (2.14), and then showing that this problem has a unique solution \( k_t \in \mathcal{K}_\vartheta \) on a bounded time interval \( [0, T(\vartheta, \vartheta_0)] \) (subsection 3.1).

(ii) Proving that the mentioned solution \( k_t \) has properties (a) and (b) in (2.18) (c) follows by the fact that \( k_t \in \mathcal{K}_{\vartheta} \). Then \( k_t \in \mathcal{K}_{\vartheta}^* \) and hence also in \( \mathcal{K}_{\vartheta}^+ \), see (2.20) and (2.21). By Proposition 2.3 it follows that \( k_t \) is the correlation function of a unique state \( \mu_t \) (subsection 3.2).

(iii) Constructing a continuation of \( k_t \) from \( [0, T(\vartheta, \vartheta_0)] \) to all \( t > 0 \) by means of the fact that \( k_t \in \mathcal{K}_{\vartheta}^+ \) (subsection 3.3).

3.1. Solving the Cauchy problem. We begin by rewriting \( L^\Delta \) (given in (2.40), (2.41)) in the following form

\[
L^\Delta = A + B, \tag{3.1}
\]

\[
(Ak)(\eta) = -E(\eta)k(\eta),
\]

\[
(Bk)(\eta) = -\int_{\mathbb{R}^d} \left( \sum_{y \in \eta} a(x - y) \right) k(\eta \cup x)dx + \sum_{x \in \eta} b(x)k(\eta \setminus x).
\]

For \( \vartheta \in \mathbb{R} \) and \( \vartheta' > \vartheta \), let \( \mathcal{L}(\mathcal{K}_\vartheta, \mathcal{K}_{\vartheta'}) \) be the Banach space of all bounded linear operators acting from \( \mathcal{K}_\vartheta \) to \( \mathcal{K}_{\vartheta'} \). Like in (2.26) we define \( A_{\vartheta' \vartheta}, B_{\vartheta' \vartheta} \in \mathcal{L}(\mathcal{K}_\vartheta, \mathcal{K}_{\vartheta'}) \), satisfying

\[
\|A_{\vartheta' \vartheta}\| \leq \frac{4\|a\|}{e^2(\vartheta' - \vartheta)^2} + \frac{\|m\|}{e(\vartheta' - \vartheta)}, \quad \|B_{\vartheta' \vartheta}\| \leq \frac{\|b\|e^{-\vartheta} + (a)e^{\vartheta'}}{e(\vartheta' - \vartheta)}. \tag{3.2}
\]
Now we set, see (2.11),

\[(S(t)k)(\eta) = \exp(-tE(\eta))k(\eta), \quad t \geq 0, \tag{3.3}\]

and then introduce the corresponding \(S_{\vartheta',\vartheta}(t) \in \mathcal{L}(\mathcal{K}_{\vartheta},\mathcal{K}_{\vartheta'}), t \geq 0.\) By the first estimate in (3.2) one shows that the map

\[ [0, +\infty) \ni t \mapsto S_{\vartheta',\vartheta}(t) \in \mathcal{L}(\mathcal{K}_{\vartheta},\mathcal{K}_{\vartheta'}) \tag{3.4} \]

is continuous and such that

\[ \frac{d}{dt} S_{\vartheta',\vartheta}(t) = A_{\vartheta',\vartheta'} S_{\vartheta',\vartheta}(t), \quad t > 0, \tag{3.5} \]

holding for each \(\vartheta'' \in (\vartheta, \vartheta').\) Note that (3.3) may be used to define a bounded multiplication operator, \(S_{\vartheta}(t) \in \mathcal{L}(\mathcal{K}_{\vartheta}) := \mathcal{L}(\mathcal{K}_{\vartheta},\mathcal{K}_{\vartheta}).\) However, in this case the map \([0, +\infty) \ni t \mapsto S_{\vartheta}(t) \in \mathcal{L}(\mathcal{K}_{\vartheta})\) would not be continuous.

For \(\vartheta' > \vartheta\) as above, we fix some \(\delta < \vartheta' - \vartheta.\) Then, for a given \(l \in \mathbb{N},\) we divide the interval \([\vartheta, \vartheta']\) into subintervals with endpoints \(\vartheta^s, s = 0, 1, \ldots, 2l + 1,\) as follows. Set \(\vartheta^0 = \vartheta, \vartheta^{2l+1} = \vartheta',\) and

\[
\begin{align*}
\vartheta^{2s} &= \vartheta + \frac{s}{l+1} \delta + s\varepsilon, & \varepsilon := (\vartheta' - \vartheta - \delta)/l, \\
\vartheta^{2s+1} &= \vartheta + \frac{s+1}{l+1} \delta + s\varepsilon, & s = 0, 1, \ldots, l.
\end{align*}
\]  

Then, for \(t > 0\) and

\[(t, t_1, \ldots, t_l) \in T_l := \{(t, t_1, \ldots, t_l) : 0 \leq t_i \leq t_{i-1}, \ldots, t_i \leq t_l \} \subset \mathbb{R}^{l+1}, \]

define

\[
\Pi^{(l)}_{\vartheta',\vartheta}(t, t_1, \ldots, t_l) = S_{\vartheta',\vartheta}(t-t_1)B_{\vartheta^{2l+1}} \cdots S_{\vartheta^{2s+1},\vartheta^{2s}}(t_{s-1} - t_{s-1+1}) \times B_{\vartheta^{2s+1}} \cdots S_{\vartheta^{2s},\vartheta^{2s}}(t_{l-1} - t_l)B_{\vartheta^{2s},\vartheta^{2s}}(t_l).
\]  

By (3.5), (3.4) and (3.1) one can prove the next statement, cf [3] Proposition 4.6].

**Proposition 3.1.** For each \(l \in \mathbb{N},\) the operators defined in (3.7) have the properties:

(i) for each \((t, t_1, \ldots, t_l) \in T_l, \Pi^{(l)}_{\vartheta',\vartheta}(t, t_1, \ldots, t_l)\) is in \(\mathcal{L}(\mathcal{K}_{\vartheta},\mathcal{K}_{\vartheta'})\) and the map

\[(t, t_1, \ldots, t_l) \mapsto \Pi^{(l)}_{\vartheta',\vartheta}(t, t_1, \ldots, t_l) \in \mathcal{L}(\mathcal{K}_{\vartheta},\mathcal{K}_{\vartheta'})\]

is continuous;

(ii) for fixed \(t_1, \ldots, t_l\) and each \(\varepsilon > 0,\) the map

\[(t_1, t_1 + \varepsilon) \ni t \mapsto \Pi^{(l)}_{\vartheta',\vartheta}(t, t_1, \ldots, t_l) \in \mathcal{L}(\mathcal{K}_{\vartheta},\mathcal{K}_{\vartheta'})\]

is continuously differentiable and such that, for each \(\vartheta'' \in (\vartheta, \vartheta'),\) the following holds

\[
\frac{d}{dt} \Pi^{(l)}_{\vartheta',\vartheta}(t_1, \ldots, t_l) = A_{\vartheta',\vartheta'} \Pi^{(l)}_{\vartheta',\vartheta}(t_1, \ldots, t_l). \tag{3.8}\]

Define

\[
T(\vartheta', \vartheta) = \frac{\vartheta' - \vartheta}{|b|e^{-\vartheta} + (a)e^{\vartheta}}. \tag{3.9}\]

Then assume that \(k_{\mu_0} \in \mathcal{K}_{\vartheta_0},\) fix some \(\vartheta_1 > \vartheta_0,\) and set

\[ T = \{ (\vartheta, \vartheta', t) : \vartheta_0 \leq \vartheta < \vartheta' \leq \vartheta_1, \quad t < T(\vartheta', \vartheta) \}. \tag{3.10}\]

**Proposition 3.2.** There exists a family of linear operators, \(\{Q_{\vartheta,\vartheta}(t) : (\vartheta, \vartheta', t) \in T\},\) each element of which is in the corresponding \(\mathcal{L}(\mathcal{K}_{\vartheta},\mathcal{K}_{\vartheta'})\) and has the following properties:
(i) the map \([0, T(\vartheta', \vartheta)) \ni t \mapsto Q_{\vartheta' \vartheta}(t) \in L(\mathcal{K}_\vartheta, \mathcal{K}_{\vartheta'})\) is continuous and \(Q_{\vartheta' \vartheta}(0)\) is the embedding \(\mathcal{K}_\vartheta \hookrightarrow \mathcal{K}_{\vartheta'}\);

(ii) for each \(\vartheta'' \in (\vartheta, \vartheta')\) and \(t < T(\vartheta'', \vartheta)\), the following holds

\[
\frac{d}{dt}Q_{\vartheta' \vartheta}(t) = L_{\vartheta'' \vartheta}^\Delta Q_{\vartheta'' \vartheta}(t). \quad (3.11)
\]

**Proof.** We go along the line of arguments used in the proof of Lemma 4.5 in [8]. Take any \(T < T(\vartheta', \vartheta)\) and then pick \(\vartheta'' \in (\vartheta, \vartheta')\) and a positive \(\delta < \vartheta'' - \vartheta\) such that also \(T < T_\delta := T(\vartheta'' - \delta, \vartheta)\). For these values of the parameters, take \(\Pi^{(l)}_{\vartheta'' \vartheta}\) as in (3.7) and then, for \(n \in \mathbb{N}\), set

\[
Q_{\vartheta'' \vartheta}^{(n)}(t) = S_{\vartheta'' \vartheta}(t) + \sum_{l=1}^n \int_0^t \int_0^{t_1} \cdots \int_0^{t_{l-1}} \Pi^{(l)}_{\vartheta'' \vartheta}(t, t_1, \ldots, t_l) dt_l \cdots dt_1. \quad (3.12)
\]

By (3.3) and the second estimate in (3.2) we have from (3.7) that

\[
\|\Pi^{(l)}_{\vartheta'' \vartheta}(t, t_1, \ldots, t_l)\| \leq \left(\frac{l}{e T_\delta}\right)^l,
\]

holding for all \(l = 1, \ldots, n\). By (3.12), for \(t \in [0, T]\), this yields

\[
\|Q_{\vartheta'' \vartheta}^{(n)}(t) - Q_{\vartheta'' \vartheta}^{(n-1)}(t)\| \leq \int_0^t \int_0^{t_1} \cdots \int_0^{t_{n-1}} \|\Pi_{\vartheta'' \vartheta}^{(n)}(t, t_1, \ldots, t_n)\| dt_l \cdots dt_n

\leq \frac{1}{n!} \left(\frac{n}{e}\right)^n \left(\frac{T}{T_\delta}\right)^n.
\]

Hence, for all \(t \in [0, T]\), \(\{Q_{\vartheta'' \vartheta}^{(n)}(t)\}_{n \in \mathbb{N}}\) is a Cauchy sequence in \(L(\mathcal{K}_\vartheta, \mathcal{K}_{\vartheta'})\). The operator \(Q_{\vartheta'' \vartheta}(t)\) in question is then its limit. The continuity in (i) follows by the fact that the convergence to \(Q_{\vartheta'' \vartheta}(t)\) is uniform on \([0, T]\). Moreover, by (3.12) we have that \(Q_{\vartheta'' \vartheta}^{(n)}(0) = S_{\vartheta'' \vartheta}(0)\), cf. (3.3), which yields the stated property of \(Q_{\vartheta'' \vartheta}(0)\). Finally, (3.11) follows from (3.8) by the same arguments. \(\square\)

From (3.11) one can get that the family mentioned in Proposition 3.2 enjoys the following ‘semigroup’ property

\[
Q_{\vartheta' \vartheta}(t + s) = Q_{\vartheta'' \vartheta'}(t)Q_{\vartheta'' \vartheta}(s), \quad (3.13)
\]

holding whenever \((\vartheta, \vartheta', t + s), (\vartheta'', \vartheta', t),\) and \((\vartheta, \vartheta'', s)\) are in \(\Upsilon\).

Now we make precise which Cauchy problem we are going to solve. Set

\[
\mathcal{D}_\vartheta = \{k \in \mathcal{K}_\vartheta : L_{\vartheta}^\Delta k \in \mathcal{K}_\vartheta\}, \quad (3.14)
\]

where \(L_{\vartheta}^\Delta\) is as in (2.29). This defines an unbounded linear operator \(L_{\vartheta}^\Delta : \mathcal{D}_\vartheta \to \mathcal{K}_\vartheta\), being the extension of the operators \(L_{\vartheta'' \vartheta}^\Delta : \mathcal{K}_{\vartheta_0} \to \mathcal{K}_{\vartheta'} \to \mathcal{K}_\vartheta\) with \(\vartheta'' \in (\vartheta_0, \vartheta)\) and all \(\vartheta_0 < \vartheta\), cf. (2.14). Then we consider the Cauchy problem (2.8) in \(\mathcal{K}_\vartheta\) with this operator \(L_{\vartheta_1}^\Delta\), and \(k_{\mu_0} \in \mathcal{K}_{\vartheta_0}\). By its (classical) solution we understand the corresponding map \(t \mapsto k_t \in \mathcal{D}_{\vartheta_1}\), continuously differentiable in \(\mathcal{K}_{\vartheta_1}\).

**Lemma 3.3.** Let \(\vartheta_0\) and \(\vartheta_1\) be as in (3.10). Then for each \(k_{\mu_0} \in \mathcal{K}_{\vartheta_0}\), the problem (2.8) as described above, cf (3.10) below, has a unique solution \(k_t \in \mathcal{K}_{\vartheta_1}\) with \(t \in [0, T(\vartheta_1, \vartheta_0)]\) given by the formula

\[
k_t = Q_{\vartheta_1 \vartheta_0}(t)k_{\mu_0}, \quad (3.15)
\]

such that \(k_t(\vartheta_0) = 1\) for all \(t \in [0, T(\vartheta_1, \vartheta_0)]\).
Clearly, \( G \) cf (2.14). As in (3.1) and (3.3), we define the corresponding multiplication operators and thus satisfies, cf (3.2),

\[
\frac{d}{dt} k_t = L_{\hat{G}^{\theta'}} k_t = L_{\hat{G}_1} k_t. \tag{3.16}
\]

By claim (i) of Proposition 3.2 we have that \( k_0 = k_{\mu_0} \). Moreover, \( k_t(\emptyset) = 1 \) for all \( t \in [0, T(\hat{G}_1, \hat{G}_0)) \) since \( k_0 = k_{\mu_0} \), see (b) in (2.13), and

\[
\left( \frac{d}{dt} k_t \right)(\emptyset) = (L_{\hat{G}^{\theta'}} k_t)(\emptyset) = 0,
\]

which follows from (2.10) – (2.9). The stated uniqueness follows by the arguments used in the proof of Lemma 4.8 in [8]. \( \square \)

**Remark 3.4.** As in the proof of Lemma 3.3 one can show that, for each \( t \in [0, T(\hat{G}_1, \hat{G}_0)) \), the following holds:

\[
Q_{\hat{G}_1, \hat{G}_0}(t) : K_{\hat{G}_0} \to D_{\hat{G}_1},
\]

see (3.13), and

\[
\frac{d}{dt} Q_{\hat{G}_1, \hat{G}_0}(t) = L_{\hat{G}^{\theta'}} Q_{\hat{G}_1, \hat{G}_0}(t).
\]

Now we construct the evolution of functions \( G_0 \to G_t \) such that, for \( k \in K_{\hat{G}} \), the following holds, cf. (2.10),

\[
\langle G_0, Q_{\theta', \theta}(t) k \rangle = \langle G_t, k \rangle, \quad t < T(\theta', \theta). \tag{3.17}
\]

To this end, we introduce, cf (2.12) and (2.13),

\[
|G|_{\theta} = \int_{\Gamma_0} |G(\eta)| \exp (\theta|\eta|) \lambda(d\eta), \tag{3.18}
\]

\[
G_{\theta} = \{ G : \Gamma_0 \to \mathbb{R} : |G|_{\theta} < \infty \}.
\]

Clearly, \( G_{\theta'} \to G_{\theta} \) for \( \theta < \theta' \); hence, we have introduced another scale of Banach spaces, cf (2.11). As in (3.1) and (3.3), we define the corresponding multiplication operators \( A_{\theta', \theta} \) and \( S_{\theta', \theta}(t) \), and also \( C_{\theta', \theta} \in \mathcal{L}(G_{\theta'}, G_{\theta}) \) which acts as

\[
(CG)(\eta) = - \sum_{x \in \eta} \sum_{y \in \eta \setminus x} a(x - y) G(\eta \setminus x) + \int_{\mathbb{R}^d} b(x) G(\eta \cup x) dx,
\]

and thus satisfies, cf (3.2),

\[
\| C_{\theta', \theta} \| \leq \frac{\| b \| e^{-\theta} + \langle a \rangle e^{\theta'}}{e(\theta' - \theta)}. \tag{3.19}
\]

Now, for the same division of \( [\theta, \theta'] \) as in (3.6), we introduce, cf (3.7),

\[
\Omega_{\theta', \theta}(t, t_1, \ldots, t_i) = S_{\theta', \theta}(t_1)C_{\theta', \theta} S_{\theta', \theta}(t_{i-1} - t_i) \cdots C_{\theta', \theta} S_{\theta', \theta}(t - t_1)
\]

\[
\times S_{\theta', \theta}(t_{i-1} - t_{i-1}) \cdots C_{\theta', \theta} S_{\theta', \theta}(t - t_i).
\]

For this \( \Omega_{\theta', \theta} \), one can get the properties analogous to those stated in Proposition 3.1.

Next, for \( n \in \mathbb{N} \), we define, cf (3.12),

\[
H_{\theta', \theta}^{(n)}(t) = S_{\theta', \theta}(t) + \sum_{l=1}^{n} \int_0^t \int_0^{t_l} \cdots \int_0^t \Omega_{\theta', \theta}(t, t_1, \ldots, t_i) dt_l \cdots dt_1. \tag{3.20}
\]
As in the proof of Proposition 3.2 by means of (3.19) we then show that the sequence \( \{H^{(n)}_{\vartheta \vartheta'}(t)\}_{n \in \mathbb{N}} \) converges in \( \mathcal{L}(\mathcal{G}_\vartheta, \mathcal{G}_\vartheta) \), uniformly on compact subsets of \([0, T(\vartheta', \vartheta))\). Let \( H_{\vartheta \vartheta'}(t) \) be the limit. Then, by the very construction in (3.20), it follows that, cf (3.17),

\[
\|H_{\vartheta \vartheta'}(t)G, k]\| = \|G, Q_{\vartheta \vartheta'}(t)k\|, \quad t \in [0, T(\vartheta', \vartheta)),
\]

holding for each \( G \in \mathcal{G}_\vartheta \) and \( k \in \mathcal{K}_\vartheta \).

3.2. The identification. Our next step is based on the following statement.

Lemma 3.5. Let \( \{Q_{\vartheta \vartheta'}(t) : (\vartheta, \vartheta', t) \in \mathcal{T}\} \) be the family as in Proposition 3.2. Then, for each \( \vartheta \) and \( \vartheta' \) and \( t \in [0, T(\vartheta', \vartheta)/2) \), it follows that that \( Q_{\vartheta \vartheta'}(t) : \mathcal{K}_\vartheta \to \mathcal{K}_{\vartheta'} \).

We prove this lemma in a number of steps. First we introduce auxiliary models, indexed by \( \sigma > 0 \), for which we construct the families of operators \( Q^\sigma_{\vartheta \vartheta'}(t) \) analogous to those in Proposition 3.2. Then we prove that these families have the property stated in Lemma 3.5. Thereafter, we show that

\[
\|G, Q^\sigma_{\vartheta \vartheta'}(t)k_0\| \rightarrow \|G, k_1\|, \quad \text{as} \ \sigma \to 0,
\]

holding for each \( G \in \mathcal{B}^*_\text{bs}(\Gamma_0) \) and \( k_0 \) as in Lemma 3.3 with \( t \in [0, T(\vartheta', \vartheta)/2) \), see (2.17). By Proposition 2.3 this yields the fact we wish to prove.

3.2.1. Auxiliary models. For \( \sigma > 0 \), we set

\[
\varphi_\sigma(x) = \exp(-\sigma|x|^2), \quad b_\sigma(x) = b(x)\varphi_\sigma(x).
\]

Let also \( L^{\Delta, \sigma} \) stand for \( L^\Delta \) as in (2.39) with \( b \) replaced by \( b_\sigma \). Note that \( \|b_\sigma\| \leq \|b\| \).

Clearly, for this \( L^{\Delta, \sigma} \), we can perform the same construction as in the previous subsection and obtain the family \( \{Q^\sigma_{\vartheta \vartheta'}(t) : (\vartheta, \vartheta', t) \in \mathcal{T}\} \) as in Proposition 3.2 with \( \mathcal{T} \) and \( T(\vartheta', \vartheta) \) given in (3.10) and (3.54), respectively. Note also that \( Q^\sigma_{\vartheta \vartheta'}(t) \) satisfy, cf. (3.11) and Remark 3.1,

\[
\frac{d}{dt}Q^\sigma_{\vartheta \vartheta'}(t) = L^{\Delta, \sigma}_{\vartheta \vartheta'}Q^\sigma_{\vartheta \vartheta'}(t) = L^{\Delta, \sigma}_{\vartheta \vartheta'}Q^\sigma_{\vartheta \vartheta'}(t).
\]

Like in (3.15) we then set

\[
k^\sigma = Q^\sigma_{\vartheta_1 \vartheta_0}(t)k_0, \quad t < T(\vartheta_1, \vartheta_0).
\]

Also as above, we construct the operators \( H^\sigma_{\vartheta_1 \vartheta_0}(t) \) such that, cf. (3.21),

\[
\|H^\sigma_{\vartheta_1 \vartheta_0}(t)G, k\| = \|G, Q^\sigma_{\vartheta_1 \vartheta_0}(t)k\|,
\]

holding for appropriate \( G \) and \( k \).

Proposition 3.6. Assume that \( Q^\sigma_{\vartheta_1 \vartheta_0} : \mathcal{K}_{\vartheta_0} \to \mathcal{K}_{\vartheta_1} \) for all \( t < T(\vartheta_1, \vartheta_0) \). Then, for all \( t < T(\vartheta_1, \vartheta_0)/2 \) and \( G \in \mathcal{B}_{\text{bs}}(\Gamma_0) \), the convergence in (3.22) holds.

Proof. Take \( \vartheta = (\vartheta_1 + \vartheta_0)/2 \) and then pick \( \vartheta' \in (\vartheta, \vartheta_1) \) such that

\[
\frac{1}{2}T(\vartheta_1, \vartheta_0) \leq \min\{T(\vartheta_1, \vartheta'); T(\vartheta, \vartheta_0)\},
\]

which is possible in view of the continuous dependence of \( T(\vartheta', \vartheta) \) on both its arguments, see (3.9). For \( t < T(\vartheta_1, \vartheta_0)/2 \), by (3.15) and (3.25) we get that

\[
k_t - k^\sigma = \int_0^t Q_{\vartheta_1 \vartheta}(t-s) \left( L^{\Delta, \sigma}_{\vartheta \vartheta'} - L^{\Delta, \sigma}_{\vartheta \vartheta'} \right) k^\sigma_s ds =: \int_0^t Q_{\vartheta_1 \vartheta}(t-s)D_{\vartheta \vartheta'}k^\sigma_s ds,
\]

where (2.39),

\[
(Dk)(\eta) = \sum_{x \in \eta} (1 - \varphi_\sigma(x)) b(x)k(\eta \setminus x),
\]
Let $\mu$ and then, for $\eta$, $k_\sigma \in \mathcal{K}_\vartheta$, which is possible since
\[ s \leq t < \frac{1}{2} T(\vartheta_1, \vartheta_0) \leq T(\vartheta, \vartheta_0), \]
see (3.27). Take $G \in B_{\text{bs}}$. Since it lies in each $\mathcal{G}_\vartheta$, and hence in $\mathcal{G}_{\vartheta_1}$, we can get
\[ H_{\vartheta_1^\vartheta}(t - s)G =: G_{t - s} \in \mathcal{G}_{\vartheta'}, \quad t - s < T(\vartheta_1, \vartheta_0)/2, \]
see (3.27). For this $G$, by (3.21) and (3.28) we have
\[ \psi_\sigma(t) := \langle \langle G, k_t - k_\sigma^0 \rangle \rangle = \int_0^t \langle \langle G_{t - s}, D_{\vartheta'} k_\sigma^0 \rangle \rangle ds \tag{3.30} \]
\[ = \int_0^t \left( \int_{\Gamma_0} \int_{\mathbb{R}^d} \frac{1}{|\eta| + 1} G_{t - s}(\eta \cup x) b(x)(1 - \varphi(x))(|\eta| + 1)k_\sigma^0(\eta) d\lambda(\eta) \right) ds. \]
To get the latter line we also used (3.29). Recall that here $G_{t - s} \in \mathcal{G}_{\vartheta'}$ and $k_\sigma^0 \in \mathcal{K}_\vartheta$ with $\vartheta < \vartheta'$. Let us prove that
\[ g_s(x) := \int_{\Gamma_0} \frac{1}{|\eta| + 1} |G_s(\eta \cup x)| \exp \left( \vartheta' |\eta| \right) \lambda(\eta) \]
lies in $L^1(\mathbb{R}^d)$ for each $s \leq \tilde{T}$. Indeed, by (3.3) and (3.18) we have
\[ \|g_s\|_{L^1(\mathbb{R}^d)} \leq e^{\vartheta'} \sup_{s \in [0, \tilde{T}]} |G_s|_{\vartheta'}. \tag{3.31} \]
We use this in (3.30) to get
\[ |\psi_\sigma(t)| \leq \sup_{s \in [0, \tilde{T}]} \|k_s\|_{\vartheta} \left\| \frac{b}{\vartheta' - \vartheta} \right\|_{\vartheta'} \int_0^t \int_{\mathbb{R}^d} g_s(x)(1 - \varphi(x)) dx ds \to 0, \quad \text{as } \sigma \to 0. \]
The latter convergence follows by (3.31) and the Lebesgue dominated convergence theorem. This completes the proof.

### 3.2.2. Auxiliary evolutions

Now we turn to proving that the assumption of Proposition 3.6 holds true. For a compact $\Lambda$, by $\Gamma_\Lambda$ we denote the set of configurations $\eta$ contained in $\Lambda$. It is a measurable subset of $\Gamma_0$, i.e., $\Gamma_\Lambda \in \mathcal{B}(\Gamma)$. Recall that $\mathcal{B}(\Gamma)$ can be generated by the cylinder sets $\Gamma_\Lambda^n$ with all possible compact $\Lambda$ and $n \in \mathbb{N}_0$. Let $\mathcal{B}(\Gamma_\Lambda)$ denote the sub-$\sigma$-field of $\mathcal{B}(\Gamma)$ consisting of $A \subset \Gamma_\Lambda$. For $A \in \mathcal{B}(\Gamma_\Lambda)$, we set $C_\Lambda(A) = \{ \gamma \in \Gamma : \gamma_\Lambda \in A \}$. Then, for a state $\mu$, we define $\mu^\Lambda$ by setting $\mu^\Lambda(A) = \mu(C_\Lambda(A))$; thereby, $\mu^\Lambda$ is a probability measure on $\mathcal{B}(\Gamma_\Lambda)$. It is possible to show, see [9], that for each compact $\Lambda$ and $\mu \in \mathcal{P}_{\exp}(\Gamma)$, the measure $\mu^\Lambda$ has density with respect to the Lebesgue-Poisson measure defined in (2.3), which we denote by $R^\Lambda_\mu$. Moreover, the correlation function $k_\mu$ and the density $R^\Lambda_\mu$ satisfy
\[ k_\mu(\eta) = \int_{\Gamma_\Lambda} R^\Lambda_\mu(\eta \cup \xi) \lambda(d\xi), \quad \eta \in \Gamma_\Lambda. \tag{3.32} \]
Let $\mu_0 \in \mathcal{P}_{\exp}(\Gamma)$ be the initial state as in Lemma 3.3. Fix some compact $\Lambda$ and $N \in \mathbb{N}$, and then, for $\eta \in \Gamma_0$, set
\[ R^\Lambda_0 N(\eta) = \begin{cases} R^\Lambda_\mu(\eta), & \text{if } \eta \subset \Lambda \text{ and } |\eta| \leq N; \\ 0, & \text{otherwise}. \end{cases} \tag{3.33} \]
Clearly, $R^\Lambda_0 N \in \mathcal{G}_\vartheta$ with any $\vartheta \in \mathbb{R}$, and $R^\Lambda_0 N(\eta) \geq 0$ for $\lambda$-almost all $\eta \in \Gamma_0$. 

Let us now consider the auxiliary model specified by \( L^{\Delta, \sigma} \), and also by \( L^\sigma \) which one obtains by replacing in (1.6) \( b \) by \( b_\sigma \), see (3.23). Then the equation for the densities obtained from the Fokker-Planck equation (1.5) takes the form

\[
\frac{d}{dt} R_t(\eta) = (L^1 R_t)(\eta)
\]

(3.34)

\[
:= -\Psi_\sigma(\eta) R_t(\eta) + \sum_{x \in \eta} b_\sigma(x) R_t(\eta \setminus x) + \int_{\mathbb{R}^d} \left( \sum_{y \in \eta} a(x - y) \right) R_t(\eta \cup x) dx,
\]

where

\[
\Psi_\sigma(\eta) := E(\eta) + \langle b_\sigma \rangle, \quad \langle b_\sigma \rangle := \int_{\mathbb{R}^d} b(x) \varphi_\sigma(x) dx.
\]

(3.35)

Set

\[
\mathcal{G}_\vartheta^+ = \{ G \in \mathcal{G}_\vartheta : G(\eta) \geq 0, \text{ for } \lambda - \text{a.a. } \eta \in \Gamma_0 \},
\]

and also

\[
\mathcal{D} = \{ R \in \mathcal{G}_0 : \Psi_\sigma R \in \mathcal{G}_0 \}, \quad \mathcal{D}^+ = \mathcal{D} \bigcap \mathcal{G}_0^+.
\]

(3.36)

**Proposition 3.7.** The operator \((L^1, \mathcal{D})\) defined in (3.34) and (3.36) is the generator of a substochastic semigroup \( S^1 = \{ S^1(t) \}_{t \geq 0} \) on \( \mathcal{G}_0 \), which leaves invariant each \( \mathcal{G}_\vartheta \), \( \vartheta > 0 \).

**Proof.** In this statement we mean that

\[
\forall t \geq 0 \quad (a) \quad S^1(t) : \mathcal{G}_0^+ \rightarrow \mathcal{D}^+;
\]

(3.37)

(b) \quad |S^1(t) R | \leq 1, \text{ whenever } |R| \leq 1 \text{ and } R \in \mathcal{G}_0^+;

(c) \quad S^1(t) : \mathcal{G}_\vartheta^+ \rightarrow \mathcal{G}_\vartheta^+, \text{ for all } \vartheta > 0.

We use the Thieme-Voigt theorem in the form of [11, Propositions 3.1 and 3.2]. By this theorem the proof amounts to checking the validity of the following inequalities:

\[
\forall R \in \mathcal{D}^+ \quad \int_{\Gamma_0} \left( L^1 R \right)(\eta) \lambda(d\eta) \leq 0,
\]

(3.38)

\[
\forall \vartheta > 0 \quad (L^\vartheta G_\vartheta)(\eta) + \varepsilon \Psi_\sigma(\eta) \leq CG_\vartheta(\eta), \quad G_\vartheta(\eta) := e^{\vartheta |\eta|},
\]

holding for some positive \( C \) and \( \varepsilon \). Recall that \( \Psi_\sigma \) is defined in (3.35). By direct inspection we get from (3.34) that the left-hand side of the first line in (3.38) equals zero for each \( R \in \mathcal{D} \). Proving the second inequality in (3.38) reduces to showing that, for each \( \vartheta > 0 \), the function

\[
\Sigma(\eta) := -E(\eta)(1 - e^{-\vartheta}) + \langle b_\sigma \rangle (e^{\vartheta} - 1) + \varepsilon \Psi_\sigma(\eta)e^{-\vartheta |\eta|}, \quad \eta \in \Gamma_0,
\]

is bounded from above, which is obviously the case. \( \square \)

The second auxiliary evolution is supposed to be constructed in \( \mathcal{G}_\vartheta \). It is generated by the operator \( \hat{L}_\vartheta \) the action of which coincides with that of \( L^{\Delta, \sigma} \), see (2.9) and (2.10), with \( b \) replaced by \( b_\sigma \). The domain of this operator is

\[
\hat{\mathcal{D}}_\vartheta = \{ q \in \mathcal{G}_\vartheta : \Psi_\sigma(\cdot q) \in \mathcal{G}_\vartheta \}.
\]

(3.39)

**Proposition 3.8.** For each \( \vartheta > 0 \), the operator \((\hat{L}_\vartheta, \hat{\mathcal{D}}_\vartheta)\) is the generator of a \( C_0 \)-semigroup \( \hat{S}_\vartheta := \{ \hat{S}_\vartheta(t) \}_{t \geq 0} \) of bounded operators on \( \mathcal{G}_\vartheta \).
Proof. As in the proof of Lemma 5.5 in [3], we pass from \( q \) to \( w \) by setting \( w(\eta) = (-1)^{\eta} q(\eta) \), and hence to \( \tilde{L}_\theta \) defined on the same domain \( (3.39) \) by the relation \( (\tilde{L}_\theta w)(\eta) = (-1)^{\eta} (\tilde{L}_\theta q)(\eta) \). Then we just prove that \((\tilde{L}_\theta, \tilde{D}_\theta)\) generates a \( C_0 \)-semigroup on \( \mathcal{G}_\theta \). In view of \((2.10), (2.30)\), we have
\[
\tilde{L}_\theta = \tilde{A} + \tilde{B} + \tilde{C}
\]
\[
(\tilde{A} w)(\eta) = -E(\eta) w(\eta), \quad (\tilde{B} w)(\eta) = \int_{\mathbb{R}^d} \left( \sum_{y \in \eta} a(x - y) \right) w(\eta \cup x) dx,
\]
\[
(\tilde{C} w)(\eta) = - \sum_{x \in \eta} b_\sigma(x) w(\eta \setminus x).
\]
By \((3.18)\) we get
\[
|\tilde{C} w|_\theta \leq e^\theta (b_\sigma) |w|_\theta,
\]
hence \( \tilde{C} \) is a bounded operator. For \( w \in \mathcal{G}_\theta^+ \), we have
\[
|\tilde{B} w|_\theta = \int_{\Gamma_0} e^{\theta |\eta|} \left( \int_{\mathbb{R}^d} \left( \sum_{y \in \eta} a(x - y) \right) w(\eta \cup x) dx \right) \lambda(d\eta)
\]
\[
= \int_{\Gamma_0} e^{\theta (|\eta| - 1)} \left( \sum_{x \in \eta \setminus \xi} a(x - y) \right) w(\eta) \lambda(d\eta)
\]
\[
\leq e^{-\theta} \int_{\Gamma_0} e^{\theta |\eta|} E(\eta) w(\eta) \lambda(d\eta) = e^{-\theta} |\tilde{A} w|_\theta \leq |\tilde{A} w|_\theta.
\]
The latter estimate allows us to apply here the Thieme-Voigt theorem, see [11] Proposition 3.1 by which \( \tilde{A} + \tilde{B} \) generates a substochastic semigroup in \( \mathcal{G}_\theta \). Thus, \( \tilde{L}_\theta \) generates a \( C_0 \)-semigroup since \( \tilde{C} \) is bounded. This completes the proof.

Now for \( R_0^{\Lambda,N} \) defined in \((3.33)\), we set
\[
q_0^{\Lambda,N}(\eta) = \int_{\Gamma_0} R_0^{\Lambda,N}(\eta \cup \xi) \lambda(d\xi), \quad \eta \in \Gamma_0.
\]
By \((3.32)\)
\[
0 \leq q_0^{\Lambda,N}(\eta) \leq k_{\mu_0}(\eta).
\]
Hence, \( q_0^{\Lambda,N} \in \mathcal{K}_{\rho_0} \). By \((3.33)\) \( R_0^{\Lambda,N} \) lies in each \( \mathcal{G}_\theta \), \( \theta \geq 0 \). At the same time,
\[
|q_0^{\Lambda,N}|_\theta = \int_{\Gamma_0} \int_{\Gamma_0} e^{\theta |\eta|} R_0^{\Lambda,N}(\eta \cup \xi) \lambda(d\eta) \lambda(d\xi)
\]
\[
= \int_{\Gamma_0} \left( \sum_{\eta \subset \xi} e^{\theta |\eta|} \right) R_0^{\Lambda,N}(\xi) \lambda(d\xi) = |R_0^{\Lambda,N}|_\beta,
\]
where \( \beta > 0 \) is to satisfy \( e^\beta = 1 + e^\theta \). Hence, \( q_0^{\Lambda,N} \in \mathcal{G}_\theta \) for each \( \theta > 0 \). In view of this, \( q_0^{\Lambda,N} \in \mathcal{D}_\theta \) for each \( \theta > 0 \), see \((3.39)\). Consider the problem in \( \mathcal{G}_\theta \)
\[
\frac{d}{dt} q_t = \tilde{L}_\theta q_t, \quad q_t |_{t=0} = q_0^{\Lambda,N}.
\]
Proof. By Proposition 3.8 the problem in (3.42) has a unique global solution given by
\[ q_t = \tilde{S}_\vartheta(t)q_0^{\Lambda,N}. \] (3.44)
On the other hand, this solution can be sought in the form
\[ q_t(\eta) = \int_{\Gamma_0} \left( S^\vartheta(t)R^\Lambda,N_0 \right)(\eta \cup \xi)\lambda(d\xi), \] (3.45)
where \( S^\vartheta \) is the semigroup constructed in Proposition 3.7. Indeed, by direct inspection one verifies that \( q_t \) in this form satisfies \( q_t \), cf the proof of Lemma 5.8 in [8]. Then, \( q_t \) lies in each \( \sigma,\vartheta \) for each \( t \in [0, T(\vartheta_1, \vartheta_0)) \).

By (3.41) it follows that \( q_0^{\Lambda,N} \in K_{\vartheta_0} \), hence we may use it in (3.25) and obtain
\[ k_t^{\Lambda,N} = Q^\sigma_{\vartheta_1,\vartheta_0}(t)q_0^{\Lambda,N}, \quad t \in [0, T(\vartheta_1, \vartheta_0)). \] (3.47)

Proposition 3.10. Let \( k_t^{\Lambda,N} \) and \( q_t \) be as in (3.47) and in (3.44), (3.45), respectively. Then, for all \( t \in [0, T(\vartheta_1, \vartheta_0)) \), it follows that \( k_t^{\Lambda,N} = q_t \).

Proof. A priori \( k_t^{\Lambda,N} \) and \( q_t \) lie in different spaces: \( K_{\vartheta_1} \) and \( G_{\vartheta} \), respectively. Note that the latter \( \vartheta \) can be arbitrary positive. The idea is to construct one more evolution \( q_0^{\Lambda,N} \rightarrow u_0 \) in some intersection of these two spaces, related to the evolutions in (3.47) and (3.41). Then the proof will follow by the uniqueness as in Proposition 3.9.

For \( \vartheta \in \mathbb{R}, \varphi_\sigma \) as in (3.23) and \( u : \Gamma_0 \rightarrow \mathbb{R} \), we set, cf (2.13) and (2.6),
\[ \|u\|_{\sigma,\vartheta} = \text{ess sup}_{\eta \in \Gamma_0} \frac{|u(\eta)| \exp(-\vartheta|\eta|)}{e(\eta; \varphi_\sigma)}, \quad e(\eta; \varphi_\sigma) := \prod_{x \in \eta} \varphi_\sigma(x), \] (3.48)
and then \( U_{\sigma,\vartheta} := \{u : \Gamma_0 \rightarrow \mathbb{R} : \|u\|_{\sigma,\vartheta} < \infty\} \). Clearly,
\[ U_{\sigma,\vartheta} \hookrightarrow K_{\vartheta}, \quad \vartheta \in \mathbb{R}, \] (3.49)
since \( \|u\|_{\vartheta} \leq \|u\|_{\sigma,\vartheta} \). Moreover, as in (2.21) we have that \( U_{\sigma,\vartheta} \hookrightarrow U_{\sigma,\vartheta'} \) for \( \vartheta' > \vartheta \). Let \( L^{\Lambda,\sigma} \) be defined as in (2.9) with \( b \) replaced by \( b_\sigma \). Then we define an unbounded linear operator \( L^{\Lambda,\sigma}_{\vartheta,u} : \mathcal{D}^{\Lambda,\sigma}_{\vartheta,u} \rightarrow U_{\sigma,\vartheta} \) with the action as just described and the domain
\[ \mathcal{D}^{\Lambda,\sigma}_{\vartheta,u} = \{u \in U_{\sigma,\vartheta} : L^{\Lambda,\sigma}_{\vartheta,u} u \in U_{\sigma,\vartheta}\}. \] (3.50)
Clearly, \( U_{\sigma,\vartheta'} \subset \mathcal{D}^{\Lambda,\sigma}_{\vartheta,u} \) for each \( \vartheta' < \vartheta \). By (3.33) and (3.40) it follows that \( q_0^{\Lambda,N}(\eta) = 0 \) if \( |\eta| > N \) or if \( \eta \) is not contained in \( \Lambda \). Then \( q_0^{\Lambda,N} \) lies in each \( U_{\sigma,\vartheta''}, \vartheta'' \in \mathbb{R}, \) and hence in the domain of \( L^{\Lambda,\sigma}_{\vartheta,u} \) given in (3.50). Thus, we can consider
\[ \frac{d}{dt} u_t = L^{\Lambda,\sigma}_{\vartheta,u} u_t, \quad u_t|_{t=0} = q_0^{\Lambda,N}. \] (3.51)
As in (3.1) we write \( L^{\Delta,\sigma}_{\vartheta,\vartheta} = A^{\sigma,u} + B^{\sigma,u} \), where \( A^{\sigma,u} \) is the multiplication operator by \(-E(\eta)\). The operator norm of \( B^{\sigma,u} \) can be estimated as follows. By (3.48) we have
\[
|u(\eta)| \leq \|u\|_{\sigma,\vartheta} \exp (\vartheta |\eta|) \prod_{x \in \eta} \varphi_\sigma(x),
\]
which yields
\[
|(B^{\sigma,u}) (\eta)| \leq \|u\|_{\sigma,\vartheta} |\eta| \exp (\vartheta |\eta|) \left( \|b\| e^{-\vartheta} + (\alpha) e^{\vartheta'} \right) \prod_{x \in \eta} \varphi_\sigma(x).
\]
Hence, the operator norm of \( B^{\sigma,u}_{\vartheta,\vartheta} \in \mathcal{L}(\mathcal{U}_{\sigma,\vartheta}, \mathcal{U}_{\sigma,\vartheta'}) \) satisfies
\[
\|B^{\sigma,u}_{\vartheta,\vartheta}\| \leq \frac{\|b\| e^{-\vartheta} + (\alpha) e^{\vartheta'}}{e(\vartheta' - \vartheta)},
\]
which coincides with that in (3.2). Then we repeat the construction made in Propositions 3.1-3.2 and Lemma 3.3 and obtain the solution of (3.51) in the form
\[
\text{see (3.39)}.
\]
Since the action of \( \hat{\mathcal{G}}_{\vartheta,\vartheta} \) is as in (3.9) whereas \( Q^{\sigma,u}_{\vartheta,\vartheta} \) satisfies, cf (3.11) and Remark 3.4
\[
\frac{d}{dt} Q^{\sigma,u}_{\vartheta,\vartheta} (t) = \left( A^{\sigma,u}_{\vartheta,\vartheta} + B^{\sigma,u}_{\vartheta,\vartheta} \right) Q^{\sigma,u}_{\vartheta,\vartheta} (t) = L^{\Delta,\sigma}_{\vartheta,\vartheta} Q^{\sigma,u}_{\vartheta,\vartheta} (t).
\]
Since \( (L^{\Delta,\sigma}_{\vartheta,\vartheta}, D^{\Delta,\sigma}_{\vartheta,\vartheta}) \subset (L^{\Delta,\sigma}_{\vartheta,\vartheta}, D^{\Delta,\sigma}_{\vartheta,\vartheta}) \), and in view of (3.24) and (3.47), (3.49), we have that
\[
\forall t \in [0, T((\vartheta_1, \vartheta_0))) \quad k_t^\vartheta = u_t. \tag{3.52}
\]
On the other hand, for \( \vartheta > 0 \) and \( u \in \mathcal{U}_{\sigma,\vartheta'} \), by (3.48) we get
\[
\int_{\Gamma_0} |u(\eta)| e^{\vartheta |\eta|} \lambda (d\eta) \leq \|u\|_{\sigma,\vartheta'} \int_{\Gamma_0} \exp ((\vartheta' + \vartheta) |\eta|) e(\eta; \varphi_\sigma) \lambda (d\eta) = \|u\|_{\sigma,\vartheta'} \exp \left( \langle \varphi_\sigma e^{\vartheta + \vartheta'} \rangle \right),
\]
Thus, \( \mathcal{U}_{\sigma,\vartheta'} \hookrightarrow \mathcal{G}_{\vartheta} \) for each \( \vartheta \in \mathbb{R} \) and \( \vartheta \geq 0 \). Likewise, one shows that \( D^{\Delta,\sigma}_{\vartheta,\vartheta} \hookrightarrow \hat{\mathcal{G}}_{\vartheta} \), see (3.39). Since the action of \( \hat{L} \) coincides with that of \( L^{\Delta,\sigma}_{\vartheta} \), by the latter embedding we have that \( (L^{\Delta,\sigma}_{\vartheta,\vartheta}, D^{\Delta,\sigma}_{\vartheta,\vartheta}) \subset (\hat{L}, \hat{\mathcal{G}}_{\vartheta}) \), holding for each \( \vartheta > 0 \). Then by the uniqueness stated in Proposition 3.9 we conclude that \( q_t = u_t \) for all \( t \in [0, T((\vartheta_1, \vartheta_0)) \). In view of (3.52), this yields \( k_t^\vartheta = u_t \), which completes the proof.

3.2.3. Proof of Lemma 3.7. We have to show that the assumption of Proposition 3.6 holds true for each \( \sigma > 0 \), which is equivalent to proving that \( k_t^\sigma \) given in (3.25) has the property
\[
\|G_0, k_t^\sigma\| \geq 0, \tag{3.53}
\]
holding for all \( t < T((\vartheta_1, \vartheta_0)) \) and \( G_0 \in B^\sigma_{\vartheta,\vartheta}(\Gamma_0) \). By definition, a cofinal sequence of \( \{\Lambda_n\}_{n \in \mathbb{N}} \) is a sequence of compact subsets \( \Lambda_n \subset \mathbb{R}^d \) such that \( \Lambda_n \subseteq \Lambda_{n+1}, n \in \mathbb{N}, \) and each \( x \in \mathbb{R}^d \) is contained in a certain \( \Lambda_n \). Let \( \{\Lambda_n\}_{n \in \mathbb{N}} \) be such a sequence. Fix \( \sigma > 0 \) and then, for given \( \Lambda_n \) and \( N \in \mathbb{N}, \) obtain \( q_0^{\Lambda_n,N} \) from \( k_{\vartheta_0} \) by (3.33), (3.40). As in [1] Appendix one can show that, for each \( G \in \mathcal{G}_{\vartheta_0} \), the following holds
\[
\lim_{n \to +\infty} \lim_{N \to +\infty} \langle G, q^{\Lambda_n,N}_0 \rangle = \langle G, k_{\vartheta_0} \rangle. \tag{3.54}
\]
Let $G_k$ be as in (3.53), and hence lie in any $G_\vartheta$. For $t \in [0, T(\vartheta_1, \vartheta_0))$ and $k_t^{\varLambda_n \varepsilon N}$ as in (3.47), by (3.26) we get
\[ \langle G_0, k_t^{\varLambda_n \varepsilon N} \rangle = \langle H_{\vartheta_0 \vartheta_1}^\vartheta(t) G_0, q_0^{\varLambda_n \varepsilon N} \rangle =: \langle G, q_0^{\varLambda_n \varepsilon N} \rangle \geq 0. \] (3.55)
The latter inequality follows by Proposition 3.10 and (3.46). Then (3.53) follows by (3.51) and (3.55).

3.3. Proof of Theorem 2.4. To complete proving the theorem we have to construct the continuation of the solution (3.15) to all $t \geq 0$ and prove the upper bound in (2.27). The lower bound follows by the fact that $k_t \in K^\vartheta$. This will be done by comparing $k_t$ with the solution of the equation (2.8) for the Surgailis model given in (2.21). If we denote the latter by $\vartheta_1$, then
\[ v_t(\eta) = (W(t) k_{\mu_0})(\eta) := \sum_{\xi \subseteq \eta} e(\xi; \psi_t) e(\eta \setminus \xi; \psi_t) k_{\mu_0}(\eta \setminus \xi). \] (3.56)
For $k_{\mu_0} \in K_{\vartheta_0}$, by (2.10) and (1.1) we get from the latter
\[ v_t(\eta) \leq \|k_{\mu_0}\| \varrho_0 \exp \left\{ \varrho_0 + \log \left( 1 + t \|b\| e^{-\varrho_0} \right) \right\}, \] (3.57)
which holds also in the case $m \equiv 0$. Thus, for a given $T > 0$, $W(t)$ with $t \in [0, T]$ acts as a bounded operator $W_{\vartheta_1 \vartheta_0}(t)$ from $K_{\vartheta_0}$ to $K_{\vartheta_1}$ with
\[ \varrho_T := \varrho_0 + \log \left( 1 + T \|b\| e^{-\varrho_0} \right). \] (3.58)
For $\vartheta \in \mathbb{R}$, we set, cf (3.9),
\[ \tau(\vartheta) = T(\vartheta + 1, \vartheta) = \left[ \|b\| e^{-\vartheta} + e(a) e^\vartheta \right]^{-1}. \] (3.59)
For $\vartheta_1 = \varrho_0 + 1$, let $k_t$ be given in (3.15) with $t \in [0, \tau(\varrho_0))$. Fix some $\kappa \in (0, 1/2)$ and set $T_1 = \kappa T(\vartheta_0)$. By Lemmas 3.3 and 3.5 we know that $k_t = Q_{\vartheta_1 \vartheta_0}(t) k_{\mu_0}$ exists and lies in $K_{\vartheta_1}$ for all $t \in [0, T_1]$. Take $\vartheta \in (\vartheta_0, \vartheta_1 + 1)$ such that $T_1 < T(\vartheta, \vartheta_0)$. Then take $\vartheta' > \vartheta$ and set, cf (3.58),
\[ \tilde{\vartheta}_1 = \max \left\{ \varrho_0 + 1; \vartheta' + \log \left( 1 + T_1 \|b\| e^{-\vartheta'} \right) \right\}. \]
For $t \in [0, T_1]$, we have
\[ v_t - k_t = \int_0^t W_{\vartheta_1 \vartheta_0}(t - s) D\vartheta \varrho k_s ds, \] (3.60)
where $k_s$ belongs to $K_{\vartheta_1}$, whereas $v_t$ and $k_t$ belong to $K_{\vartheta_1}$. By (3.56) and (3.1) the action of $D$ in (3.60) is
\[ (Dk)(\eta) = \left( \sum_{x \in \eta} \sum_{y \in \eta \setminus x} a(x - y) \right) k(\eta) + \int_{\mathbb{R}^d} \left( \sum_{y \in \eta \setminus x} a(x - y) \right) k(\eta \cup x) dx, \]
hence
\[ v_t(\eta) - k_t(\eta) \geq 0 \text{ for } \lambda\text{-almost all } \eta \in \Gamma_0 \text{ since } W(t) \text{ is positive, see (3.56) and (2.22)} \]
and $k_s \in K_{\vartheta_1}^\vartheta \subset K_{\vartheta_1}^\vartheta$, see (2.19), (2.20), and Lemma 3.5. Since $k_t$ in (3.60) is in $K_{\vartheta_1}$, we have that
\[ 0 \leq k_t \leq v_t, \quad t \in [0, T_1], \] (3.61)
which by (3.57) yields $k_t \in K_{\vartheta_1 \vartheta_1}$ and the bound in (2.27) for such $t$, see (3.58). Set $T_2 = \kappa T(\tilde{\vartheta}_1)$, $\vartheta_2 = \vartheta_1 + 1$ and consider $k_t^{(2)} = Q_{\vartheta_2 \vartheta_0}(t) k_{\vartheta_1}$ with $t \in [0, T_2]$. Clearly,
$k^{(2)}_t = k_{T_1 + t}$ for $T_1 + t < T(\vartheta_0 + 1, \vartheta)$, see (3.13), and hence is a continuation of $k_t$ to $[T_1, T_2]$. Now we repeat this procedure $d$ times and obtain

$$k^{(n)}_t = Q_{\vartheta_n T_{n-1}}(t) k_{T_{n-1}},$$

where $\vartheta_n = \vartheta_{T_{n-1}} + 1$ and

$$T_n = \kappa \tau(\vartheta_{T_{n-1}}),$$

$$\vartheta_{T_n} = \vartheta_{T_{n-1}} + \log \left( 1 + T_{n-1} ||b|| e^{-\vartheta_{T_{n-1}}} \right), \quad \vartheta_{T_0} := \vartheta_0.$$ 

The continuation to all $t > 0$ will be obtained if we show that

$$\sum_{n=1}^{N} T_n = +\infty.$$ 

Assume that this is not the case. From the second line in (3.62) we get

$$T_{n-1} = (e^{\vartheta_{T_n}} - e^{\vartheta_{T_{n-1}}}) / ||b||.$$

Hence

$$\sum_{n=1}^{N} T_n = \left( e^{\vartheta_{TN}} - e^{\vartheta_0} \right) / ||b||.$$ 

Thus, the mentioned series converges if the sequence $\{\vartheta_{T_n}\}_{n \in \mathbb{N}}$ is bounded, say by $\bar{\vartheta}$. However, in this case one cannot get $T_n \to 0$ as $n \to +\infty$, for it contradicts the first line in (3.62) since

$$\tau(\vartheta) \geq \left[ e(a) e^{\bar{\vartheta}} + ||b|| e^{-\vartheta_0} \right]^{-1},$$

see (3.59). Clearly, the upper bound in (3.61) hold on each $[T_{n-1}, T_n]$. This completes the proof.

### 4. The Global Boundedness

Here we prove Theorem 2.5. Let $\Delta$ be a closed cubic cell such that

$$\inf_{x \in \Delta} a(x) =: a_\Delta > 0,$$  

(4.1)

which is possible since $a$ is continuous. For $\eta$ contained in a translate of $\Delta$, $|\eta| \geq 2$, and $x \in \eta$, we then have

$$\sum_{y \in \eta \setminus x} a(x - y) \geq a_\Delta (|\eta| - 1) \geq a_\Delta.$$  

(4.2)

For a translate of $\Delta$, we consider the observables $N^n_\Delta : \Gamma \to \mathbb{N}_0$ defined as follows:

$$N^n_\Delta(\gamma) = |\gamma_\Delta|^n, \quad n \in \mathbb{N}.  \quad (4.3)$$

Then

$$N_\Delta(\gamma) = \sum_{x \in \gamma} I_\Delta(x),$$

$$N^n_\Delta(\gamma) = \sum_{l=1}^{n} l! S(n, l) \sum_{\{x_1, \ldots, x_l\} \subset \gamma} I_\Delta(x_1) \cdots I_\Delta(x_l), \quad n \geq 2,$$

where $I_\Delta$ is the indicator function of $\Delta$ and $S(n, l)$ is a Stirling numbers of the second kind, equal to the number of distinct ways of dividing $n$ labeled items into $l$ unlabeled groups. It has the following representation, cf [13],

$$S(n, l) = \frac{1}{l!} \sum_{s=0}^{l} (-1)^{l-s} \binom{l}{s} s^n.$$

(4.4)

Then, for $\mu \in \mathcal{P}_{\exp}(\Gamma)$, by (2.6) we have that

$$\mu(N^n_\Delta) = \sum_{l=1}^{n} S(n, l) \int_{\Delta} \cdots \int_{\Delta} \ell^{(l)}(x_1, \ldots, x_l) dx_1 \cdots dx_l.$$  

(4.5)
For \( l \in \mathbb{N} \), we set
\[
F^{(l)}_{\Delta}(\gamma) = \sum_{\{x_1, \ldots, x_l\} \subseteq \gamma} I_{\Delta}(x_1) \cdots I_{\Delta}(x_l) \tag{4.6}
\]
\[
= \frac{1}{l!} N_{\Delta}(\gamma) (N_{\Delta}(\gamma) - 1) \cdots (N_{\Delta}(\gamma) - l + 1) .
\]
And also \( F^{(0)}_{\Delta}(\gamma) \equiv 1 \). Then we can rewrite (4.3) as follows
\[
N_{\Delta}^{n}(\gamma) = \sum_{l=1}^{n} \frac{l!}{l!} S(n, l) F^{(l)}_{\Delta}(\gamma) . \tag{4.7}
\]
An easy calculation yields
\[
F^{(l)}_{\Delta}(\gamma \cup x) - F^{(l)}_{\Delta}(\gamma) = \prod_{i=1}^{l} I_{\Delta}(x_i) F^{(l-1)}_{\Delta}(\gamma) . \tag{4.8}
\]
For \( \mu_t \) as in Theorem 2.4, we set
\[
q^{(0)}_{\Delta}(t) = 1, \quad q^{(l)}_{\Delta}(t) = \mu_t F^{(l)}_{\Delta}, \quad l \in \mathbb{N} . \tag{4.9}
\]
By (4.5), (4.6) and (4.7) it follows that
\[
q^{(l)}_{\Delta}(0) = \frac{1}{l!} \int_{\Delta} \cdots \int_{\Delta} k^{(l)}_{\mu_0}(x_1, \ldots, x_l) dx_1 \cdots dx_l . \tag{4.10}
\]
Since \( \mu_0 \) is in \( \mathcal{P}_{\exp}(\Gamma) \), one finds \( \vartheta \in \mathbb{R} \) such that \( k^{(l)}_{\mu_0}(x_1, \ldots, x_l) \leq e^{\vartheta} \), cf (2.3). By (4.10) this yields
\[
q^{(l)}_{\Delta}(0) \leq \left[ V(\Delta) e^{\vartheta} \right]^{l} / l!, \quad l \in \mathbb{N} . \tag{4.11}
\]
Recall that \( a_{\Delta} \) is defined in (4.1), see also (4.2). Set
\[
b_{\Delta} = \int_{\Delta} b(x) dx, \quad \kappa_{\Delta} = \max \left\{ V(\Delta) e^{\vartheta}; b_{\Delta}/a_{\Delta} \right\} , \tag{4.12}
\]
where \( \vartheta \) is as in (4.11).

The proof of the lemma below is based on the following elementary arguments. Let \( u : [0, +\infty) \rightarrow \mathbb{R} \) be continuously differentiable with the derivative satisfying
\[
u'(t) \leq b - au(t), \quad a, b > 0 . \tag{4.13}
\]
Then
\[
u(t) \leq \nu(0) e^{-at} + \frac{b}{a} (1 - e^{-at}) , \quad t \geq 0 ,
\]
which, in particular, means that
\[
u(t) \leq \max \{ \nu(0); b/a \} , \tag{4.14}
\]
and also: for each \( \varepsilon > 0 \), there exists \( \tau_{\varepsilon} \geq 0 \) such that
\[
\forall t \geq \tau_{\varepsilon} \quad \nu(t) \leq \varepsilon + b/a . \tag{4.15}
\]

**Lemma 4.1.** Let \( \Delta \) be as in (4.1) and \( \mu_t, t \geq 0 \) be as in Theorem 2.4 and hence \( q^{(l)}_{\Delta}(0) \) satisfies (4.7) with some \( \vartheta \). Let \( \kappa_{\Delta} \) be as in (4.12) for these parameters. Then
\[
\forall t \geq 0 \quad q^{(l)}_{\Delta}(t) \leq \kappa_{\Delta}^{l} / l!, \quad l \in \mathbb{N} . \tag{4.16}
\]
Proof. By (1.4) we have that
\[
\frac{d}{dt} q^{(l)}(t) = \mu_t(LF^{(l)}_\Delta),
\]
which by means of (4.8) can be written
\[
\frac{d}{dt} q^{(l)}(t) = bq^{(l-1)}_\Delta(t) - \int_\Gamma \left( \sum_{x \in \gamma} \left( \sum_{y \in \gamma \setminus x} a(x-y) \right) F^{(l-1)}_\Delta(\gamma \setminus x) \right) \mu_t(d\gamma). \tag{4.17}
\]
By (4.7) it follows that
\[
\sum_{x \in \gamma} F^{(l-1)}_\Delta(\gamma \setminus x) = lF^{(l)}_\Delta(\gamma).
\]
We apply this in (4.17) and obtain, cf (4.13) and (4.12),
\[
\frac{d}{dt} q^{(l)}_\Delta(t) \leq bq^{(l-1)}_\Delta(t) - aq^{(l)}_\Delta(t), \quad l \in \mathbb{N}. \tag{4.18}
\]
For \(l = 1\), by (4.9) and (4.14) we get from the latter that (4.16) holds. Now we assume that (4.16) holds for a given \(l-1\). It yields in (4.18)
\[
\frac{d}{dt} q^{(l)}_\Delta(t) \leq bq^{(l-1)}_\Delta(t) - aq^{(l-1)}_\Delta(t) - \frac{b}{l-1}aq^{(l)}_\Delta(t),
\]
from which by (4.13) we obtain that (4.16) holds also for \(l\). \(\square\)

Proof of Theorem 2.5. By means of the evident monotonicity
\[
\mu(N^{n-1}_\Lambda) \leq \mu(N^{n+1}_\Lambda), \quad \mu(N^n_\Lambda) \leq \mu(N^n_{\Lambda'}), \quad \text{for } \Lambda \subset \Lambda',
\]
we conclude that it is enough to prove the statement for: (a) \(n = 2s\); (b) \(\Lambda\) being a finite sum of the translates of the cubic cell \(\Delta\) as in Lemma 4.1. Let \(m\) be such that
\[
\Lambda = \bigcup_{l=1}^m \Delta_l,
\]
where the cells \(\Delta_l\) are such that the intersection of each two distinct ones is of zero Lebesgue measure. By the estimate
\[
\left( \sum_{l=1}^n a_l \right)^2 \leq n \sum_{l=1}^n a_l^2,
\]
we prove that
\[
N^{2s}_\Lambda(\gamma) \leq m^{2s-1} \sum_{l=1}^m N^{2s}_{\Delta_l}(\gamma), \quad s \in \mathbb{N}_0.
\]
Then by Lemma 4.1 and (4.7) we obtain
\[
\mu_t(N^{2s}_\Lambda) \leq m^{2s}T_{2s}(\kappa_\Delta) = [V(\Lambda)]^{2s} \left( T_{2s}(\kappa_\Delta)/[V(\Delta)]^{2s} \right),
\]
where $T_n$ is the Touchard polynomial

$$T_n(x) := \sum_{i=1}^{n} S(n, l) x^l,$$

with $S(n, l)$ given in [4.4], see [13] eq. (3.4)], and

$$\tilde{\kappa}_\Delta := V(\Delta) \max \left\{ e^{\varphi}; \|b\|/a_{\Delta} \right\},$$

cf (4.12). This proves (2.25). This proves (2.25).

If the initial state $\mu_0$ is such that each $k_{\mu_0}^{(1)} \in C_b((\mathbb{R}^d)^l)$ – the set of bounded continuous functions, then so is $k_{\mu}^{(1)}$ for all $t > 0$. This can be proved by repeating the corresponding proof in [4]. As in (2.25) we have, see also (4.5),

$$\mu_t(N_\Delta) = \int_\Delta k_t^{(1)}(x) dx.$$

By taking a sequence of $\Delta$ shrinking up to a given $x$ and applying (4.16) we obtain

$$k_t^{(1)}(x) \leq \max \left\{ k_{\mu_0}^{(1)}(x); b(x)/a(0) \right\} \leq \max\{\|k_{\mu_0}^{(0)}\|_{L^{\infty}(\mathbb{R}^d)}; \|b\|/a(0)\},$$

(4.19)

which proves the bound in (1.8) for $k_t^{(1)}$. Note that the smaller bound in (4.19) coincides with the corresponding bound in the exactly soluble Surgailis model in which the mortality rate $m(x)$ is substituted by $a(0)$. That is, the competition here amounts to the appearance of an effective mortality $a(0)$. Another important observation regarding the competition in this model is based on (4.15). Let $\Lambda$ be compact and $k_t^{(1)}$ satisfy (4.19). Then for an arbitrary $\varepsilon > 0$, one finds $\tau(\varepsilon, \Lambda)$, dependent also on $\mu_0$, such that, for all $x \in \Lambda$ and $t \geq \tau(\varepsilon, \Lambda)$, the following holds

$$k_t^{(1)}(x) \leq \frac{b(x)}{a(0)} + \varepsilon.$$

That is, after some time the density at each point of $\Lambda$ approaches a certain level, independent of the initial distribution of the entities in $\Lambda$.

Let us now prove the validity of the second estimate in (1.8). The bound for $k_t^{(2)}(x, x)$ can be obtained from (4.16) in the way similar to that used in getting (4.19). To bound $k_t^{(2)}(x, y)$ with $x \neq y$, let us take two disjoint cells $\Delta_x$ and $\Delta_y$. Both are of side $h > 0$ and such that: (a) $x \in \Delta_x$ and $y \in \Delta_y$; (b) $\Delta_x \to \{x\}$ and $\Delta_y \to \{y\}$ as $h \to 0$. Then we set

$$F_h(\gamma) = \left[ \sum_{z \in \gamma} (I_{\Delta_z}(z) - I_{\Delta_u}(z)) \right]^2.$$

For the state $\mu_t$, we have

$$0 \leq \mu_t(F_h) = q_{\Delta_z}^{(2)}(t) + q_{\Delta_u}^{(2)}(t) - 2 \int_{\Delta_x} \int_{\Delta_y} k_t^{(2)}(z_1, z_2) d z_1 d z_2.$$

By (4.12) and (4.16) this yields

$$\int_{\Delta_x} \int_{\Delta_y} k_t^{(2)}(z_1, z_2) d z_1 d z_2 \leq \frac{1}{2} \max\{\kappa_{\Delta_z}^2; \kappa_{\Delta_u}^2\} \leq \frac{h^{2d}}{2} \max\{e^{2\varphi}; \|b\|/a_h(0)\}^2,$$

where $a_h = \min\{a_{\Delta_z}; a_{\Delta_u}\}$. Passing here to the limit $h \to 0$ and taking into account the continuity of $k_t^{(2)}$ and $a$ we obtain the second inequality in (1.8). This completes the proof.
