Received: May 10, 2014; Revised: August 20, 2014; Accepted: September 6, 2014

Background: Well-documented studies reported several pharmacological properties for crocin, the active compound of Crocus sativus, such as its antitumor, radical scavenging, antidepressant, and memory-enhancing effects.

Objectives: We aimed to evaluate the possible cytotoxic activity of crocin on B lymphocytes in human myeloma (U266 cell line) after 24- and 48-hour treatment.

Materials and Methods: For this purpose, cell viability was determined by the colorimetric MTT assay and cell death pattern was evaluated using Annexin V-FITC/propidium iodide (PI) apoptosis detection kit. ROS (reactive oxygen species) production and DNA fragmentation were assessed using 2′,7′-dichlorofluorescein diacetate (DCFH-DA) kit and PI staining, respectively.

Results: The highest concentration of crocin significantly decreased ROS production after 48 hours of treatment. However, crocin had no effect on the expression level of HSP (Heat shock protein). Additionally, its administration caused a mild decline in cell viability and a mild increase in the population of DNA fragmented cells as well as apoptosis.

Conclusions: In our study, no prominent effect was seen; therefore, in order to have a better perspective of crocin activity against cancerous cell lines, further studies are highly recommended.

Keywords: Apoptosis; DNA Fragmentation; Necrosis; Crocus
3. Materials and Methods

3.1. Materials

This study was performed using the following items: Annexin V-FITC apoptosis/necrosis detection kit and fluorescent probe 2’,7’-dichlorofluorescein diacetate (DCFH-DA) (Abcam, USA), 3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyl tetrazolium (MTT) and propidium iodide (PI) (Sigma, USA), RPMI 1640, FBS (fetal bovine serum), penicillin and streptomycin (Gibco, USA), rabbit polyclonal Hsp70 antibody, rabbit polyclonal Hsp90 antibody, anti-rabbit IgG horseradish peroxidase-conjugated antibody, mouse monoclonal β-actin antibody (Cell signaling, USA), polyvinylidene fluoride (PVDF) membrane (Bio-Rad, USA) and enhanced chemiluminescences (ECL) reagent for western blot detection (Pierce).

3.2. Extraction, Identification and Purification of Crocin

The stigmas of Crocus sativus (saffron) were collected from Ghaen, Khorasan Razavi, east of Iran and a sample was kept in the Herbarium of the School of Pharmacy, Mashhad University of Medical Sciences. The procedure of crocin identification and purification were carried out as previously reported (17).

3.3. Cell Culture

U266 (C151, B lymphocyte human myeloma) cell line was purchased from Pasteur Institute, Tehran, Iran. Cells were incubated at 37°C, with 90% humidity, and 5% CO₂. Cell culture was done in RPMI 1640 medium enriched by 10% fetal bovine serum (heat inactivated), 100 U/mL penicillin and 100 µg/mL streptomycin.

3.4. MTT Assay

Cell viability was evaluated by the colorimetric MTT assay as previously reported (18, 19). In a 96-well plate (4 × 10⁴ cells/well) cells were treated with crocin 50, 250, and 500 µM. After 24 and 48 hour incubation periods, cells were incubated with MTT solution at the concentration of 5 mg/ml for 3 hours at 37°C. Subsequently, medium was aspirated and dimethyl sulfoxide (DMSO) was added to dissolve the formazan crystals. Finally, the absorbance at 545 nm (reference wavelength: 630 nm) was determined using Stat Fax 2100 ELISA reader (UK).

3.5. Assessment of DNA Fragmentation

Propidium iodide (PI) staining was employed to assess the DNA fragmentation. Based on the method of de Lima et al. (with insignificant adjustments), following the treatment of cells with crocin 50, 250 and 500 µM in a 6-well plate (5 × 10⁵ cells/well) for 24 and 48 hours, cells were washed by PBS and subjected to 15 minutes incubation with RNase A (150 µg/ml) at 37°C (20). Then, cells were incubated with PI solution (100 µg/ml PI, 0.1 % Triton X-100 and 0.1 % sodium citrate) for 30 minutes at 4°C. As the final step, flow cytometric evaluation of fluorescence and data analysis were done by BD FACSCalibur cytometer (Beckton-Dickenson, USA) and CellQuest (USA) software, respectively.

3.6. Determination of ROS Production

Production of ROS in U266 cells following the treatment with crocin was evaluated using 2’,7’-dichlorofluorescein diacetate (DCFH-DA) kit. After the incubation periods, cells were treated with DCF-DA 20 µM for 30 minutes at 37°C, washed with cold PBS and suspended in PBS. Finally, the fluorescence intensity of dichlorofluorescein was evaluated by FACSCalibur cytometer (Beckton-Dickenson, USA) and data analysis was done using Cell Quest (USA) software.

3.7. Evaluation of Phosphatidylserine Externalization

To monitor apoptotic events, a commercially available Annexin V-FITC/PI apoptosis detection kit was used. Cells were incubated with Annexin V-FITC (5 µL) and PI (5 µL) for 5 minutes in dark at room temperature. Flow cytometric assessment of 1×10⁴ events were carried out through FL-1 filter (530 nm) and FL-2 filter (585 nm).

3.8. Western Blot Analysis of the Expression of Heat Shock Proteins 70 and 90

In order to extract the proteins, cells were washed twice with ice-cold phosphate-buffered saline (PBS) and lysed as previously described (21), using lysis buffer. Subsequently, separation of the extracted proteins was carried out using 12% SDS polyacrylamide gel electrophoresis (SDS-PAGE) and transferred to polyvinylidene fluoride (PVDF) membranes. Next, membranes were blocked by 5% skim milk at room temperature, overnight. Blots were incubated in the presence of antibodies: Hsp70 (cell signaling #4872), and Hsp90 (cell signaling #4874) at the dilution of 1:1000 for 2 hours at room temperature. Blots were washed 3 times in TBST solution (TBS with 0.1% Tween 20)
and incubated with horseradish peroxidase-conjugated anti-rabbit antibody (cell signaling #7074) at the dilution of 1:3000 for 1 hour at room temperature and washed 3 times with TBST solution. The analysis of protein bands was performed using UVtec software (UK). Protein levels were normalized against β-actin intensity.

3.9. Statistical Analysis

For each group, results are shown as mean ± SD. By analysis of variance (ANOVA) and Dunnett as the posttest, differences between control and other groups were examined using InStat 3.05 software for Windows and P < 0.05 was considered significant.

4. Results

4.1. Cell Viability

According to our results from MTT assay, after 24 hours, crocin (250 and 500 µM) significantly reduced cell viability and proliferation compared with control (P < 0.01). However, after 48 hours incubation only crocin 500µM resulted in a significant decrease in the number of viable cells (Figure 2).

4.2. Assessment of DNA Fragmentation

The population of cells with fragmented DNA were calculated by flow cytometric measurement of PI staining. In comparison with the control group, following both incubation periods, crocin at all doses increased the percentage of cells detected with DNA fragmentation (P < 0.01) (Figure 3).

**Figure 5.** Evaluation of Apoptosis or Necrosis of U266 Cells Following 24 and 48-hour Treatment with crocin Examined by Annexin V/PI Test (early Apoptotic cells were Annexin V [+] and PI [-]; Late Apoptotic cells were Annexin V [+] and PI [+]; Necrotic Cells Were Annexin V [-] and PI [+]; and the Living cells Annexin V [-] and PI [-])

A and B flow cytometry histograms of treated groups and control after 24 and 48 hours, respectively. C and D bar charts show apoptosis and necrosis as mean ± SD of three separate experiments, respectively (*) and **represent P < 0.05 and P < 0.01, respectively.
4.3. Determination of Reactive Oxygen Species Production

Generation of ROS was assessed by a commercially available kit. DCFH-DA, a nonpolar and nonfluorescent chemical, freely crosses the cell membrane and is hydrolyzed to the nonfluorescent DCFH by intracellular esterase. In the presence of ROS, DCFH will be oxidized to dichlorofluorescein (DCF) which is greatly fluorescent. As shown in Figure 4, only crocin 500 µM could significantly decrease ROS production after 48 hours of treatment (P < 0.01).

4.4. Evaluation of Phosphatidylserine Externalization

Flow cytometric analysis of phosphatidylserine externalization as the apoptotic surface marker was performed using Annexin V-FITC commercial kit. Our results demonstrated that apoptosis was significantly induced by crocin (250 and 500 µM) following 24 and 48 hours. Treatment with crocin 500 µM for 48 hours resulted in the most profound apoptosis as compared with the control group. However, regarding the necrosis, no significant alterations were recorded (Figure 5).

4.5. Western Blot analysis of the Expression of Heat Shock Proteins 70 and 90

The levels of HSP 70 and 90 were determined using western blot analysis. As compared with the control group, treatment of cells with crocin did not change the expression of these proteins considerably and differences between treated groups and control were insignificant after both incubation times (Figures 6 and 7).

5. Discussion

Proteomic findings have shown that crocin can attach to a broad range of cellular macromolecules such as structural proteins, membrane transporters, and enzymes involved in redox homeostasis and signal transduction. β-Actin-like protein 2 has been recognized as one of the target proteins of crocin. Actin filaments maintain cell morphology and mediate functions such as adhesion, motility, exocytosis, endocytosis and cell division (22). According to the mentioned mechanism, crocin might have destructive or useful effects on cells. Based on the fact that apoptosis plays an important role in the life span of normal and cancer cells, agents that are able to alter apoptosis rate could possibly influence the steady-state cell populations (23). Thus, in the present study crocin effects on U266 cell line were evaluated regarding cell death pattern, production of reactive oxygen species, DNA fragmentation and the expression of HSP 70 and 90 proteins.

Apoptotic activity of crocin (1, 2, and 4 mM) and crocin liposomal form (0.5 and 1 mM) on HeLa and MCF-7 cells was evaluated. As compared to non-malignant cell line (L929), crocin caused notable cytotoxic effects on HeLa and MCF-7 when the encapsulated form of crocin was used. Moreover, flow cytometric examination showed a sub-G1 peak proposing the role of apoptosis in crocin cytotoxicity (24). Hoshyar et al. reported that although crocin is able to augment the sub-G1 population, caspases activity and Bax/Bcl-2 ratio in the gastric adenocarcinoma
(AGS) cells, these factors remained at the normal level in human normal fibroblast skin cells (HFS-P13) (25). Xu et al. demonstrated that the proliferation of HL-60 cells was efficiently inhibited by crocin and the number of cells in G0/G1 phase was increased. Authors proposed that inhibition of Bcl-2 and activation of Bax might be the main causes of apoptosis induction in HL-60 cells (26). Based on our data, crocin reduced cell viability and proliferation at higher doses at which an increase in apoptosis rate is noticeable. It seems that an increase in the apoptotic cell percentage might be due to the amplification of DNA fragmentation as assessed by PI staining. Crocin at the highest dose led to a significant decline in ROS generation, which is justified by its antioxidant properties. This activity has been reported previously (27).

Three main families of heat shock proteins (HSPs) are high molecular weight HSPs such as HSP90, HSP70, and small HSPs (28). While these proteins are expressed at a low level under normal physiological conditions, a variety of environmental stresses could augment their expression (29). In our study, the levels of HSP 70 and 90 were not altered following crocin treatment as compared with the negative control group. It has been reported that when the cell death takes place in a short period of time, the time for HSPs to rearrange to their effective form or when the cell death takes place in a short period of time, no prominent effect (even at high concentrations) on apoptosis because of DNA fragmentation. Because in our study, no significant alterations in comparison with the negative control group that might be due to variation of these parameters (30-32). Altogether, crocin showed little cytotoxic effects on U266 cell line and increased the expression level of HSPs. Our western blot analysis results showed no significant alterations in comparison with the control group that might be due to variation of these parameters (30-32). Altogether, crocin showed little cytotoxic effects on U266 cell line and increased the expression level of HSPs. Because in our study, no prominent effect (even at high concentrations of crocin) was seen, in order to have a better perspective of its activity against cancerous cell lines, further studies are highly recommended.
