Packing arborescences in random digraphs

Carlos Hoppen∗ Roberto F. Parente† Cristiane M. Sato‡

May 20, 2016

Abstract

We study the problem of packing arborescences in the random digraph $D(n,p)$, where each possible arc is included uniformly at random with probability $p = p(n)$. Let $\lambda(D(n,p))$ denote the largest integer $\lambda \geq 0$ such that, for all $0 \leq \ell \leq \lambda$, we have $\sum_{i=0}^{\ell-1}(\ell - i)|\{v : d^+(v) = i\}| \leq \ell$. We show that the maximum number of arc-disjoint arborescences in $D(n,p)$ is $\lambda(D(n,p))$ a.a.s. We also give tight estimates for $\lambda(D(n,p))$ depending on the range of $p$.

1 Introduction and main result

Many important problems in discrete mathematics deal with packing structures with some desired property into a larger structure, and their goal is typically to find as many disjoint structures with the desired property as possible. Several classical results in combinatorial optimization fit into this general framework. For instance, the maximum matching problem can be seen as packing vertex-disjoint edges. We also highlight Tutte’s [19] and Nash-Williams’s [18] results on packing spanning trees, as well as Menger’s [17] and Mader’s [16] results on packing paths. See the book by Cornuéjols [6] for many more examples.

Given the extensive literature on this topic, it is only natural that there is a great number of packing results in extremal combinatorics and random structures. For instance, the problem of packing Hamiltonian cycles has been studied quite intensively since the 1980s (see [3, 4, 5, 8, 10, 13, 14, 15]). Recently, Gao, Pérez-Giménez and the third author [11] obtained results concerning packing spanning trees in random graphs As usual, given a function $p : \mathbb{N} \to [0, 1]$ and a positive integer $n$, we let $G(n,p)$ be the random graph on $[n] = \{1, \ldots, n\}$ such that each edge is included independently with probability $p$. Moreover, given a sequence of probability spaces $(\Omega_i, \mathcal{F}_i, \Pr_i)_{i \in \mathbb{N}}$, we say that a sequence of events $(A_i)_{i \in \mathbb{N}}$ holds asymptotically almost surely (a.a.s. for short) if $\Pr_n(A_n) \to 1$ as $n \to \infty$.

The result stated here is not the strongest result obtained in [11].
Theorem 1.1 (Pu–Pérez-Giménez–Sato [11]). For $p = p(n) \in [0, 1]$, the maximum number of edge-disjoint spanning trees in $G(n, p)$ is $\min \{ \delta(G(n, p)), [m(G(n, p))/(n - 1)] \}$ a.a.s.

One of the main ingredients in the proof of Theorem 1.1 is the following classical result proved by Tutte and Nash-Williams.

Theorem 1.2 (Tutte [19] and Nash-Williams [18]). Given a graph $G = (V, E)$ and an integer $k \geq 0$, $G$ contains $k$ edge-disjoint spanning trees if and only if, for every partition of $V$ with $\ell$ parts, the number of edges with ends in different parts is at least $k(\ell - 1)$.

It is quite natural that this result (which is actually a min-max relation) can be successfully used for random graphs since the partition condition is essentially an expansion condition and random graphs are well known to have nice expansion properties.

Our main result is an analogue of Theorem 1.1 for digraphs. A digraph $D = (V, A)$ is given by its finite set $V$ of vertices and its set $A \subseteq \{(u, v) \in V^2: u \neq v\}$ of arcs. We say that an arc $(u, v)$ leaves $u$ and enters $v$, or, alternatively, that it points at $v$. The underlying graph of a digraph $D = (V, A)$ is the graph (actually multigraph) obtained by ignoring orientations on arcs. Our result deals with packing arborescences, which are an analogue of spanning trees in digraphs. Indeed, an arborescence of a digraph is a spanning sub-digraph such that its underlying graph is a rooted tree and each vertex except the root has in-degree 1 and the root has in-degree zero. Roughly speaking, an arborescence is a spanning tree with the arcs “pointing away” from the root. Let $\mathcal{D}(n, p)$ denote the random digraph on $[n] = \{1, \ldots, n\}$ such that each arc is included independently at random with probability $p$. Let $\tau(\mathcal{D}(n, p))$ denote the maximum number of arc-disjoint arborescences in $\mathcal{D}(n, p)$. For every digraph $D$ and $v \in D$, let the in-degree $d^i_D(v)$ of $v$ be the number of arcs entering $v$ in $D$, while the out-degree $d^o_D(v)$ of $v$ is the number of arcs leaving $v$ in $D$. Our main result may be stated as follows.

Theorem 1.3. For every $p = p(n) \in [0, 1]$, we have that a.a.s.

$$\tau(\mathcal{D}(n, p)) = \lambda(\mathcal{D}(n, p)), \quad (1)$$

where $\lambda(\mathcal{D}(n, p))$ is the maximum integer $\lambda \geq 0$ such that, for all $0 \leq \ell \leq \lambda$,

$$\sum_{i=0}^{\ell-1} (\ell - i)|\{v: d^i_{\mathcal{D}(n, p)}(v) = i\}| \leq \ell. \quad (2)$$

Moreover,

(a) if $p = (\log(n) - h(n))/(n - 1)$ with $h(n) = \omega(1)$, then $\lambda(\mathcal{D}(n, p)) = 0$ a.a.s.;

(b) if $p = (\log(n) + h(n))/(n - 1)$ with $h(n) = o(\log n)$ and $h(n) = O(\log \log n)$, then $\lambda(\mathcal{D}(n, p)) \in \{\delta^m, \delta^m + 1\}$ a.a.s.;

(c) if $p = (\log(n) + h(n))/(n - 1)$ with $h(n) = o(\log n)$ and $h(n) = \Omega(\log \log n)$, then $\lambda(\mathcal{D}(n, p)) \sim \delta^m$ a.a.s.

One interesting feature of our result is that $\tau(\mathcal{D}(n, p))$ has a very strong relation with the number of vertices with low degrees. As in the graph case, our condition is a natural one, and it is easy to see that one cannot achieve more than $\lambda(\mathcal{D}(n, p))$ arborescences.
Indeed, if $\tau(D(n,p)) \geq \ell$, then every vertex of $D(n,p)$ whose in-degree is $\ell - i$ must be the root of at least $i$ arborescences, and thus $\tau(D(n,p)) \leq \lambda(D(n,p))$.

Similarly to the undirected case, the core of our proof relies on a result on combinatorial optimization, which was proved by Frank [9] and is an analogue of Tutte and Nash-Williams result for digraphs. Instead of dealing with partitions, Frank’s result imposes conditions on subpartitions. A subpartition of a set $S$ is a set of pairwise disjoint non-empty subsets of $S$. Note that, unlike a partition, a subpartition does not need to include every element of $S$. For every digraph $D = (V,A)$ and $S \subseteq V$, let $d_D^\text{in}(S)$ denote the number of arcs entering $S$ (from $V \setminus S$). For future reference, let also $d_D^\text{out}(S)$ be the number of arcs leaving $S$ (to $V \setminus S$) in $D$.

**Theorem 1.4** (Frank [9]). Let $D = (V,A)$ be a digraph and let $k \geq 0$ be an integer. Then $D$ contains $k$ arc-disjoint arborescences if, and only if, for every subpartition $\mathcal{P}$ of $V$,

$$\sum_{U \in \mathcal{P}} d_D^\text{in}(U) \geq k(|\mathcal{P}| - 1).$$

(3)

One of the difficulties of working with subpartitions instead of partitions is that some vertices may be not included in any part and the arcs entering such vertices do not contribute to the summation in (3), which is something that did not occur in the graph case.

Recently, Bal, Bennett, Cooper, Frieze, and Pralat [2] proved that in the random digraph process (where the arcs are added one-by-one) in the step where there is single a vertex with in-degree zero, the digraph contains an arborescence a.a.s.\(^2\). The problem of packing Hamiltonian cycles has also been recently studied by Ferber and Long [7].

**Organization of the paper:** This paper is organized as follows. In Section 2, we introduce the main definitions and notation used in the paper. In Section 3, we present the main properties of $D(n,p)$ that are used: in Section 3.2 we study properties of the degrees in $D(n,p)$; in Section 3.3 we show the relation between $\lambda(D(n,p))$ and the minimum in-degree; and in Section 3.4 we prove a few basic expansion properties of $D(n,p)$. Finally, in Section 4 we combine the results from Section 3 with the result by Frank (Theorem 1.4) to complete the proof of Theorem 1.3.

## 2 Definitions and notation

In this section, we define the main concepts used in this paper. We will repeat a few definitions already presented in the introduction so that the reader can easily find any of them.

**Definition 2.1.** (Random digraph $D(n,p)$) Given a function $p = p(n): \mathbb{N} \to [0,1]$, let $D(n,p)$ denote the random digraph with vertex-set $[n] = \{1,2,\ldots,n\}$ such that each of the $n(n-1)$ arcs is included independently at random with probability $p$.

**Definition 2.2.** (Degrees) Given a digraph $D = (V,A)$ and $v \in V$, the in-degree of $v$, denoted by $d_D^\text{in}(v)$, is $|\{(u,v): (u,v) \in A\}|$. That is, $d_D^\text{in}(v)$ is the number of arcs “entering” $v$. The out-degree of $v$, denoted by $d_D^\text{out}(v)$, is $|\{(v,u): (v,u) \in A\}|$. That\(^2\)Their result is actually about rainbow arborescences
is, $d^\text{out}(v)$ is the number of arcs “leaving” $v$. We define $\delta^\text{in}(D) = \min_{v \in V} d^\text{in}_D(v)$ and $\delta^\text{out}(D) = \min_{v \in V} d^\text{out}_D(v)$.

**Definition 2.3.** (Cuts) Given a digraph $D = (V, A)$ and disjoint set $S, S' \subseteq V$, we define $A_D(S, S')$ as the set of arcs $(u, v) \in A$ such that $u \in S$ and $v \in S'$.

**Definition 2.4.** (Induced digraphs) Given a digraph $D = (V, A)$ and $S \subseteq V$, we define $D[S]$ as the digraph with vertex-set $S$ with edge-set $A_D[S] = \{(u, v) \in A : u \in S, v \in S\}$.

**Definition 2.5.** (Arborescence) An arborescence of a digraph $D = (V, A)$ is a digraph $T = (V, A_T)$ where $A_T \subseteq A$ such that the underlying graph of $T$ is tree and each vertex except the root has in-degree 1 and the root has in-degree zero.

**Definition 2.6.** Given a digraph $D = (V, A)$, let $\tau(D)$ denote the maximum number of arc-disjoint arborescences in $D$.

**Definition 2.7.** Given a digraph $D = (V, A)$, let $\lambda(D)$ denote the maximum integer $\lambda \geq 0$ such that, for all $0 \leq \ell \leq \lambda$,

$$\sum_{i=0}^{\ell-1}(\ell - i)|\{v : d^\text{in}_D(v) = i\}| \leq \ell. \quad (4)$$

We use $d^\text{in}(v)$ to denote $d^\text{in}_D(v)$ for ease of notation. Similarly, $d^\text{out}(v) = d^\text{out}_D(v)$, $\delta^\text{in} = \delta^\text{in}(D(n, p))$, $\delta^\text{out} = \delta^\text{out}(D(n, p))$, $\tau = \tau(D(n, p))$ and $\lambda = \lambda(D(n, p))$, and so on.

In all results in this paper, except stated otherwise, the probability space is the one defined by $D(n, p)$ and the asymptotics are for $n$ going to infinity. We use standard asymptotic notation, which may be found in [12, Section 1.2].

In many proofs, we will use the well known subsequence principle, which states that, if $x$ is a constant and $(x_n)$ is a real sequence whose subsequences always have a subsequence converging to $x$, then $x_n \to x$.

## 3 Properties of the random digraph $D(n, p)$

In this section, we study the behaviour of the degrees in $D(n, p)$. We also prove some simple properties about cuts in $D(n, p)$. In Section 3.1, we state two basic results on binomial random variables that are used throughout the paper. For basic probabilistic results (such as Markov’s and Chebyshev’s inequality), we refer the reader to Alon and Spencer [1].

### 3.1 Properties of binomial random variables

In this section, we state two results on binomial random variables.

**Theorem 3.1** (Chernoff’s bounds [12]). Let $X_1, \ldots, X_n$ denote $n$ independent Bernoulli variables. Let $X = \sum_{i=1}^n X_i$ and let $\mu = \mathbb{E}[X]$. Then, for any $0 < \tau < 1$,

$$\Pr(X \geq (1 + \tau)\mu) \leq e^{-\tau^2\mu/3}, \quad (5)$$

$$\Pr(X \leq (1 - \tau)\mu) \leq e^{-\tau^2\mu/2}. \quad (6)$$
Lemma 3.2 (Lemma 16 [11]). For every constant \( \eta > 0 \) there exist positive constants \( C_1 \) and \( C_2 \) such that the following holds for any function \( 0 \leq p = p(n) \leq 1/\sqrt{n} \) and every integer \( 0 < k \leq (1 - \eta)n \). Let \( X \sim \text{Bin}(n, p) \). Then,

\[
\Pr(X \leq k) = C \left( \frac{e^{-pn}}{\sqrt{k}} \right) \left( \frac{epn}{k} \right)^k, \quad \text{with } C_1 \leq C \leq C_2.
\] (7)

3.2 Degrees in \( D(n, p) \)

In this section, we present some results on the minimum in-degree and out-degree in \( D(n, p) \). We also prove some properties of vertices with low degree.

The following lemma is an application of Lemma 3.2 applied to the in-degrees and out-degrees of \( D(n, p) \).

Lemma 3.3. Let \( \varphi \geq 0.9, 0 < \eta < 1 \) be constants. There exist constants \( C_1 > 0 \) and \( C_2 > 0 \) such that, for any function \( \alpha = \alpha(n) \in (0, 1 - \eta) \) and any function \( p \) satisfying \( 0.9 \log n/(n - 1) \leq p \leq \varphi \log n/(n - 1) \), the following holds\(^3\):

(i) There exists \( C = C(n) \in [C_1, C_2] \) such that, for every \( v \in [n] \),

\[
\Pr \left( d_{\text{in/out}}(v) \leq \alpha p(n - 1) \right) = \frac{C}{\sqrt{\alpha p(n - 1)}} \exp \left( -p(n - 1) \left( 1 - \alpha \log \left( \frac{\alpha}{\alpha} \right) \right) \right).
\]

(ii) \( \Pr \left( \delta_{\text{in/out}} \leq \alpha p(n - 1) \right) \leq \frac{C_2}{\sqrt{\alpha p(n - 1)}} \exp \left( \log n - p(n - 1) \left( 1 - \alpha \log (\varphi/e) \right) \right) \):

(iii) \( \Pr \left( \delta_{\text{in/out}} > \alpha p(n - 1) \right) \leq \frac{\sqrt{\alpha p(n - 1)}}{C_1} \exp \left( p(n - 1) \left( 1 - \alpha \log (e/\alpha) \right) - \log n \right) \).

(iv) \( \Pr \left( \exists v \in [n] \text{ s.t. } \min \{d_{\text{in}}(v), d_{\text{out}}(v)\} \leq \alpha p(n - 1) \right) \)

\[
\leq \frac{(C_2)^2}{\alpha p(n - 1)} \exp \left( \log n - 2p(n - 1) \left( 1 - \alpha \log \left( \frac{\alpha}{\alpha} \right) \right) \right).
\]

Proof. The proof of (i)–(iii) is basically the same as the proof of [11, Lemma 18]. We include it here for the sake of completeness.

For every \( v \in V \), the in-degree \( d_{\text{in}}(v) \) of \( v \) has distribution \( \text{Bin}(n - 1, p) \). Thus, by Lemma 3.2, there exist \( C_1 \) and \( C_2 \) (depending only on \( \eta \)) and a constant \( C = C(n) \in [C_1, C_2] \) such that

\[
\Pr \left( d_{\text{in}}(v) \leq \alpha p(n - 1) \right) = C \left( \frac{e^{-p(n-1)}}{\sqrt{\alpha p(n - 1)}} \right) \left( \frac{e}{\alpha} \right)^{\alpha p(n-1)}
\]

\[
= \frac{C}{\sqrt{\alpha p(n - 1)}} \exp \left( -p(n - 1) \left( 1 - \alpha \log \left( \frac{\alpha}{\alpha} \right) \right) \right).
\] (8)

\(^3\)Here we use \( d_{\text{in/out}}(v) \) to denote either \( d_{\text{in}}(v) \) or \( d_{\text{out}}(v) \).
This proves (i). Let $Y$ denote the number of vertices $v \in [n]$ such that $d^\text{in}(v) \leq \alpha p(n-1)$. Then, by (8), we have that

$$\mathbb{E}(Y) \geq \frac{C_1}{\sqrt{\alpha p(n-1)}} \exp \left( \log n - p(n-1) \left(1 - \alpha \log \left(\frac{e}{\alpha}\right)\right) \right)$$

and

$$\mathbb{E}(Y) \leq \frac{C_2}{\sqrt{\alpha p(n-1)}} \exp \left( \log n - p(n-1) \left(1 - \alpha \log \left(\frac{e}{\alpha}\right)\right) \right).$$

Thus, (ii) follows by applying Markov’s inequality. Since the in-degrees of the vertices are independent random variables, $Y$ is a binomial random variable with probability $p'$ given by (8). Thus, $\text{Var}(Y) = np'(1-p') \leq \mathbb{E}Y$ and so, by Chebyshev’s inequality, we have that

$$\Pr(Y = 0) \leq \frac{\text{Var}(Y)}{(\mathbb{E}Y)^2} \leq \frac{1}{\mathbb{E}Y} \leq \frac{\sqrt{\alpha p(n-1)}}{C_1} \exp \left( - \log n + p(n-1) \left(1 - \alpha \log \left(\frac{e}{\alpha}\right)\right) \right),$$

since $p(n-1) \leq \varphi \log n$ and we proved (iii). The proof for $\delta^\text{out}$ is analogous.

For any $v \in [n]$, (iv) follows trivially from (9) (and its analogue for $d^\text{out}(v)$) and the fact that $d^\text{in}(v)$ and $d^\text{out}(v)$ are independent random variables.

**Corollary 3.4.** Let $h(n) = o(\log n)$ be a function. Let $p = p(n) = (\log(n) + h(n))/(n-1)$. Then $\delta^\text{in} = o(\log n)$ a.a.s.

**Proof.** It suffices to prove the result for $h(n) \geq 0$. Let $\alpha \in (0, 1)$ be a constant. Note that $\beta := 1 - \alpha \log (e/\alpha)$ is a constant less than 1. Lemma 3.3(iii) leads to

$$\Pr(\delta^\text{in} > \alpha p(n-1)) \leq \frac{\sqrt{\alpha p(n-1)}}{C_1} \exp \left( \beta (\log n + h(n)) - \log n \right) = o(1).$$

**Corollary 3.5.** Let $p = p(n) = (\log(n) + h(n))/(n-1)$ be such that $h(n) = O(\log \log n)$. There exists a constant $C > 0$ such that $\delta^\text{in} \leq C$ a.a.s.

**Proof.** Since $h(n) = O(\log \log n)$, there exists $C > 0$ such that $h(n) < C \log \log n$ for $n$ sufficiently large. The expected number of vertices with in-degree $C$ in $\mathcal{D}(n, p)$ is

$$n \binom{n-1}{C} p^C (1-p)^{n-C-1} \geq \exp (\log n + C \log \log n - C \log C - (n-1)p + o(1)) \geq \exp (-h(n) + C \log \log n - C \log C + o(1)).$$

Since the in-degrees of distinct vertices are independent, by Chebyshev’s inequality, the minimum in-degree is at most $C$ a.a.s.

Let $F(x) = 1 - x + x \log x$. This is a continuous and strictly decreasing function for $x \in (0, 1)$. Moreover, $\lim_{x \to 1^-} F(x) = 1$ and $F(1) = 0$. In particular, for every $\phi > 1$, there exists a single $\alpha \in (0, 1)$ such that $F(\alpha) = 1/\phi$. 

6
Corollary 3.6. Let $\phi > 1$ be a constant. Let $\alpha \in (0,1)$ be such that $F(\alpha) = 1 - \alpha + \alpha \log \alpha = 1/\phi$. For $p = p(n) \sim \phi \log(n)/(n - 1)$, we have that $\delta^m \sim \alpha p(n - 1)$ and $\delta^{out} \sim \alpha p(n - 1)$ a.a.s.

Proof. Let $\gamma = \gamma(n)$ be such that $\gamma(n) \log n = p(n - 1)$. Thus, $\gamma \sim \phi$. Let $\varepsilon \in (0, \min\{\alpha, 1 - \alpha\})$ be a constant.

We have that $\lim_{n \to \infty} \gamma(n) F(\alpha + \varepsilon) < F(\alpha) \lim_{n \to \infty} \gamma(n) = 1$ and then by Lemma 3.3(iii), we have that $\delta^m \leq (\alpha + \varepsilon) p(n - 1)$ with probability going to 1. On the other hand, since $\lim_{n \to \infty} (\gamma F(\alpha - \varepsilon)) > 1$, by Lemma 3.3(ii), we have that $\delta^m \geq (\alpha - \varepsilon) p(n - 1)$ a.a.s. The proof for $\delta^{out}$ is similar.

Definition 3.7. We say that a vertex $v \in [n]$ is $\varepsilon$-in-light if $d^m(v) \leq \delta^m + \varepsilon np$ and $\varepsilon$-out-light if $d^{out}(v) \leq \delta^{out} + \varepsilon np$.

Definition 3.8. (Neighbourhoods) Given a digraph $D = (V, A)$ and $v \in V$, let $\Gamma^m_B(v) = \{u \in V : (u, v) \in A\}$ and let $\Gamma^{out}_B(v) = \{u \in V : (v, u) \in A\}$.

Lemma 3.9. Let $\varphi > 0.9$ be a constant. There exist positive constants $\varepsilon, C$ and $n_0$ such that, for any $0.9 \log n(n - 1) \leq p \leq \varphi \log n(n - 1)$, with probability at least $1 - n^{-C}$, there is no pair $(u, v)$ of $\varepsilon$-in-light vertices such that $uv \in A$ or $\Gamma^m(v) \cap \Gamma^m(u) \neq \emptyset$ and there is no pair $(u, v)$ of $\varepsilon$-out-light vertices such that $uv \in A$ or $\Gamma^{out}(v) \cap \Gamma^{out}(u) \neq \emptyset$.

Proof. We claim that it is possible to choose $\alpha$ and $\varepsilon$ so that the RHS of the inequalities in Lemma 3.3(iii) and (i) (with $\alpha$ replaced by $\alpha + \varepsilon$) are at most $Dn^{-0.19}$ and $Dn^{-0.7}$, respectively, for a positive constant $D$. This implies that

$$\Pr(\delta^m > (\alpha(n - 1) p) \leq Dn^{-0.19} \quad \text{and} \quad \Pr(d^m(v) \leq (\alpha + \varepsilon) p(n - 1)) \leq Dn^{-0.7}, \forall v \in V.$$ (10)

Let $S$ be the set of vertices $v \in [n]$ such that $d^m(v) \leq (\alpha + \varepsilon) p(n - 1)$. Then, for any vertices $u, v \in V$, by our choice of $\alpha$ and $\varepsilon$, we have that

$$\Pr(uv \in A, u \in S \quad \text{and} \quad v \in S) = pPr(v \in S | uv \in A) Pr(u \in S | uv \in A) \leq (1 + o(1)) p D^2 n^{-1.4}.$$ 

Since we have at most $n(n - 1)$ choices for $(u, v)$ and $p \leq \varphi \log n/(n - 1)$, the expected number of pairs of adjacent vertices in $S$ is $(1 + o(1)) \varphi D^2 n^{-0.4} \log n$. Thus, the probability that there are adjacent $\varepsilon$-in-light vertices is at most $Dn^{-0.19} + (1 + o(1)) \varphi D^2 n^{-0.4} \log n \leq (1/2)n^{-0.18}$ for sufficiently large $n$.

For any vertices $u, v, z \in V$, by our choice of $\alpha$ and $\varepsilon$, we have that

$$\Pr(zu, zv \in A, u \in S \quad \text{and} \quad v \in S) = p^2 Pr(v \in S | zv \in A) Pr(u \in S | zv \in A) \leq (1 + o(1)) D^2 p^2 n^{-1.4}.$$ 

Hence, since we have at most $n(n - 1)(n - 2)$ choices for $(u, v, z)$ and $p \leq \varphi \log n/(n - 1)$, the expected number of pairs of adjacent $\varepsilon$-in-light vertices is $\varphi D^2 n^{-0.4} \log^2 n$ and the result follows as above.

Finally we show how to choose $\alpha$ and $\varepsilon$ to obtain the desired bounds for the probabilities in (10). To this end, let $F(x) = 1 - x + x \log x$ be the function defined above, and let $\beta$ be the constant such that $\beta \sim (n - 1)/\log n$. By hypothesis, $0.9 \leq \beta \leq \varphi$. Choose $\alpha$ so
that $\beta F(\alpha) = 0.8$. Then the RHS of Lemma 3.3(iii) becomes $O(1) \exp(-0.2 \log n + (1/2) \log \log n) \leq O(n^{-0.19})$. We can then choose $\varepsilon > 0$ so that $\beta F(\alpha + \varepsilon) = 0.7$ and the RHS of Lemma 3.3(i) becomes $O(1) \exp(-\beta \log n F(\alpha + \varepsilon) - (1/2) \log \log n) = O(1) \exp(-0.7 \log n - (1/2) \log \log n)$.

The next result follows immediately from Chernoff’s inequality (Theorem 3.1).

**Lemma 3.10.** Let $\psi = \psi(n) = \omega(1)$. Let $p = p(n)$ be such that $p \cdot (n-1) = \psi \log n$. Then there exists $0 \leq \phi = o(1)$ such that a.a.s. for all $v \in [v]$ we have that $(1 - \phi)p(n-1) \leq d^\text{in}(v) \leq (1 + \phi)p(n-1)$ and $(1 - \phi)p(n-1) \leq d^\text{out}(v) \leq (1 + \phi)p(n-1)$.

For a function $p : \mathbb{N} \rightarrow [0,1]$ and integers $n,k \in \mathbb{N}$, we consider the random variable $Y_k = Y_k(D(n,p))$ that counts the number of vertices of in-degree $k$ in $D(n,p)$.

**Definition 3.11.** Let $\delta^* = \delta^*(D(n,p))$ denote the minimum integer $k \geq 0$ such that $E[Y_k] \geq 1$ in $D(n,p)$.

The following result shows the relation between $\delta^*$ and $\delta^\text{in}$.

**Lemma 3.12.** Let $p = p(n) \sim \log(n)/(n-1)$. Then $\delta^\text{in} \in \{\delta^*-1,\delta^*,\delta^*+1\}$ a.a.s. Moreover, we have that, if $E[Y_{\delta^*-1}] = o(1)$, then $\delta^\text{in} \in \{\delta^*,\delta^*+1\}$ and, if $E[Y_{\delta^*-1}] = \Omega(1)$, then $\delta^\text{in} \in \{\delta^* - 1,\delta^*\}$.

**Proof.** It straightforward to show that there exists $k^*(n) = o(\log n)$ such that $E[Y_{k^*(n)}] = \omega(1)$. Thus, $\delta^* = o(\log n)$. For every $k = o(\log n)$, we have that

$$E[Y_{k-1}] / E[Y_k] \sim k/(n-1)p$$  \hspace{1cm} (11)

First assume that $E[Y_{\delta^*-1}] = o(1)$. By Markov’s inequality and by (11), we have that $\delta^\text{in} \geq \delta^*$ a.a.s.

Again by (11), we have that $E[Y_{\delta^*+1}] \sim np/\delta^* \cdot E[Y_{\delta^*}] = \omega(1)$. Hence, by Chebychev’s inequality (using the independence of the in-degrees), we have $\Pr(Y_{\delta^*+1} = 0) = o(1)$, so that $\delta^\text{in} \leq \delta^* + 1$ a.a.s. The proof for the case $E[Y_{\delta^*-1}] = \Omega(1)$ is similar. The result then follows by the subsequence principle.

### 3.3 Estimating $\lambda(D(n,p))$

In this section, we give tight estimates for $\lambda = \lambda(D(n,p))$ depending on the range of $p$.

**Lemma 3.13.** Let $\phi > 1$ be a constant. If $p = p(n) \sim \phi \log(n)/(n-1)$, then $\lambda \sim \delta^\text{in}$.

**Proof.** By Corollary 3.6, for $\alpha \in (0,1)$ such that $1 - \alpha + \alpha \log(\alpha) = 1/\phi$, we have $\delta^\text{in} \sim \alpha p(n-1)$ a.a.s. Given $\varepsilon > 0$, Lemma 3.3(i) ensures that there is $0 < \beta < 1$ (depending on $\alpha$ and $\varepsilon$) such that, for any vertex $v$, we have

$$\Pr(d^\text{in}(v) \leq \alpha(1 + \varepsilon)p(n-1)) = \Theta\left(n^{-\beta}\right).$$

Since the in-degrees of distinct vertices are independent, we may apply Chernoff’s inequality (Theorem 3.1) to the binomial random variable counting the number of vertices whose in-degree is at most $\alpha(1 + \varepsilon)p(n-1)$ to conclude that there are $\Theta(n^{1-\beta})$ such vertices a.a.s. Since $n^{1-\beta} = \omega(\alpha(1 + \varepsilon)p(n-1))$, this implies that $\lambda \leq \alpha(1 + \varepsilon)p(n-1) \sim (1+\varepsilon)\delta^\text{in}$ a.a.s. Since $\lambda \geq \delta^\text{in}$ holds trivially, our result follows.
Lemma 3.14. Let \( p = p(n) = (\log(n) + h(n))/(n - 1) \) be such that \( h(n) = O(\log \log n) \). Then \( \lambda(D(n, p)) \in \{ \delta^m, \delta^m + 1 \} \) a.a.s.

Proof. Let \( I = \{ \delta^*, \delta^* + 1 \} \). First assume that \( \mathbb{E}[Y_{\delta^* - 1}] = o(1) \). By Lemma 3.12, we have \( \delta^m \in I \) a.a.s. Moreover, \( \lambda > k + 1 \) implies that \( Y_{k+1} \leq k + 2 \). Thus, \( \Pr(\lambda > \delta^m + 1) \leq \sum_{k \in I} \Pr(Y_{k+1} \leq k + 2) + \Pr(\delta^m \notin I) = \sum_{k \in I} \Pr(Y_{k+1} \leq k + 2) + o(1) \). Since \(|I| = 2\), it suffices to show that \( \Pr(Y_{k+1} \leq k + 2) = o(1) \) for \( k \in I \). To prove this, let \( k \in I \). The definition of \( \delta^* \) implies that \( \mathbb{E}[Y_k] \geq 1 \), and Corollary 3.5 implies that there exists \( C > 0 \) such that \( \delta^m \leq C \) a.a.s. Since \( \delta^m \in I \) a.a.s., we have that \( k = O(1) \). Moreover, \( \mathbb{E}[Y_{k+1}] \sim np/k \cdot \mathbb{E}[Y_k] \), so that \( \mathbb{E}[Y_{k+1}] \geq np/(k + o(1)) = \omega(1) \). By Chernoff’s inequality (Theorem 3.1), \( \Pr(Y_{k+1} \leq (1/2)\mathbb{E}[Y_{k+1}]) \leq \exp(-A\log n) \), where \( A > 0 \). Thus, \( Y_{k+1} > k + 2 \) a.a.s. and so \( \lambda \leq \delta^m + 1 \) a.a.s.

The proof is similar for the case \( \mathbb{E}[Y_{\delta^* - 1}] = \Omega(1) \). The result then follows by the subsequence principle. 

Lemma 3.15. Let \( p = p(n) = (\log(n) + h(n))/(n - 1) \) be such that \( h(n) = o(\log n) \) and \( h(n) = \Omega(\log \log n) \). Then \( \lambda(D(n, p)) \sim \delta^m \) a.a.s.

Proof. Let \( \varepsilon > 0 \) be a constant. Let \( T = \lceil (1 + \varepsilon)\delta^m \rceil \). The proof is very similar to the proof for Lemma 3.14. We will address only the case where \( \mathbb{E}[Y_{\delta^* - 1}] = o(1) \). By Lemma 3.12, we have that \( \delta^m \in I := \{ \delta^*, \delta^* + 1 \} \) a.a.s. Moreover, for any \( k \), \( \delta^m = k \) and \( \lambda > T \) implies that \( Y_T \leq T + 1 \). By Corollary 3.4, we have that \( \delta^m = o(\log n) \) and so \( T = o(\log n) \) as well. Then, we have that

\[
\frac{\mathbb{E}[Y_T]}{\mathbb{E}[Y_k]} \sim \left( \frac{np}{k} \right)^{T-k} = \omega(k).
\]

Since \( \mathbb{E}[Y_k] = \Omega(1) \), we have that \( Y_T = \omega(T) \) a.a.s. by Chernoff’s inequality (Theorem 3.1), which implies that \( \lambda \leq T \) a.a.s. 

The following result follows immediately from Lemma 3.10 and the fact that \( \lambda \) is between the minimum and the maximum in-degree.

Corollary 3.16. Let \( \phi = \phi(n) = \omega(1) \) be a function. Let \( p = p(n) \sim \phi \log(n)/(n - 1) \). We have that \( \lambda(n) \sim p(n - 1) \) a.a.s.

3.4 Expansion properties

In this section, we investigate properties of the cuts of \( D(n, p) \). We start by proving a simple result about the number of arcs going from a “large” set to another “large” set of vertices.

Lemma 3.17. Let \( f = f(n) \to \infty \) and let \( \zeta \) be a positive constant. There exist positive constants \( n_0 \) and \( C \) such that, for every \( n > n_0 \) and \( p = p(n) \in [f(n)/n, 1] \), the probability that there exist disjoint sets \( S, S' \subseteq [n] \) with size at least \( \zeta n \) such that \( |A(S', S)| < \zeta^2 n^2 p/2 \) is at most \( n^{-C} \).
Proof. Let \( S, S' \subseteq [n] \) be such that disjoint sets with size at least \( \zeta n \). Then \( |A(S, S')| \) has distribution \( \text{Bin}(|S'| |S|, p) \). Thus, \( \mathbb{E}(|A(S', S)|) = |S||S'||p \) and by Chernoff’s inequality (Theorem 3.1), we have

\[
\Pr \left( |A(S', S)| \leq \frac{|S||S'|p}{2} \right) \leq \exp \left( -\frac{\mathbb{E}(|S||S'|p)}{4} \right). \tag{13}
\]

By union bound, the probability that there exist disjoint sets \( S, S' \subseteq [n] \) with size at least \( \zeta n \) such that \( |A(S', S)| < \zeta^2 n^2 p/2 \) is at most

\[
\sum_{s, s' \geq \zeta n} \binom{n}{s} \binom{n}{s'} \exp \left( -\frac{\zeta^2 n^2 p}{4} \right) \leq 4^n \exp \left( -\frac{\zeta^2 n^2 p}{4} \right) = \exp \left( 2n - \frac{\zeta^2 n^2 p}{4} \right),
\]

and the result follows since \( np \geq f \to \infty \).

Next we prove a lemma about the number of induced arcs in sets that are “not too large”. Later we will use this lemma to argue that many arcs must leave such sets.

**Lemma 3.18.** Let \( f = f(n) \to \infty \) and let \( \phi \) be a positive constant. There exist positive constants \( \zeta, n_0 \) and \( C \) such that for every \( n > n_0 \) and \( p = p(n) \in [f/n, 1] \), the probability that there exists \( S \subseteq [n] \) with size \( |S| \leq \zeta n \) such that \( |A[S]| > \phi n|S|p \) is at most \( e^{-Cf^2} \).

**Proof.** Let \( \zeta > 0 \) be sufficiently small so that \( e\zeta/\phi \leq e^{-1/\phi^2} \). Let \( S \subseteq [n] \) be a set with size \( s \leq \zeta n \). If \( s \leq \phi np \), then \( |A[S]| \leq s(s - 1) \leq \phi np(s - 1) \leq \phi np s \). So assume \( s \geq \phi np \). Then the probability that \( |A[S]| > \phi np s \) is at most \( \left( \frac{1}{\phi np} \right)^{\phi np s} \). Thus, the expected number of sets \( S \) with size at \( \zeta n \) with \( |A[S]| > \phi np |S| \) is at most

\[
\sum_{\phi np \leq s \leq \zeta n} \frac{n}{s} \binom{n}{s} \frac{s^2}{[\phi np]} \cdot \left( \frac{\phi}{\phi np} \right)^{\phi np s} \cdot \left( \frac{\phi}{\phi np} \right)^{\phi np - 1} \leq \sum_{\phi np \leq s \leq \zeta n} \left( \frac{\phi}{\phi np} \right)^{\phi np - 1} \cdot \left( \frac{\phi}{\phi np} \right)^{\phi np - 1} \leq \sum_{\phi np \leq s \leq \zeta n} \left( \frac{\phi}{\phi np} \right)^{\phi np - 1} \leq 2(\beta - \frac{np}{\phi})^{\phi np} \leq e^{-C(np)^2} \leq e^{-Cf^2},
\]

for a constant \( C \) and sufficiently large \( n \). The result then follows by Markov’s inequality.

In the next lemma, we compare \( \delta^{in}(S) \) and \( \delta^{in} \) in the range where \( p = (1+\Omega(1)) \log n/(n-1) \) for \( S \) of size from 2 to \( n-2 \).
Lemma 3.19. Let \( \psi \) be a positive constant. There exist positive constants \( \varepsilon \) and \( n_0 \) such that, for \( p = p(n) \in [(1 + \psi) \log n/(n-1), 1] \) the probability that there exists a set \( S \subset [n] \) with \( 2 \leq |S| \leq n-2 \) such that \( d^{in}(S) < 1.5 \delta^{in} \) is at most \( n^{-\varepsilon} \).

Proof. Let \( \gamma(n) \) be such that \( p(n-1) = \gamma(n) \log n \). First assume that \( \gamma(n) \geq 100 \). Let \( 0 < \varepsilon_1 < 5/2 - \sqrt{6}, \tau = 2(1+\varepsilon_1)/10 \) and \( \varepsilon_2 > 0 \) be such that \( 2(1-\tau)(1-\varepsilon_1) \geq 1.5(1+\varepsilon_2) \).

Let \( S \subseteq [n] \) and let \( \bar{S} = [n] \setminus S \). Then \( d^{in}(S) = d^{out}(\bar{S}) = |A(S, \bar{S})| \) which is distributed as \( \text{Bin}(s\bar{s}, p) \) where \( s = |S| \) and \( \bar{s} = |\bar{S}| \). Then, by Chernoff’s inequality (Theorem 3.1) and the union bound, the probability that there exist a set \( S \subset [n] \) with \( 2 \leq |S| \leq n-2 \) such that \( d^{in}(S) < (1-\tau)s\bar{p} \) is at most

\[
\sum_{2 \leq s \leq n-2} \binom{n}{s} \exp\left(-\frac{\tau^2 s\bar{p}}{2}\right) = 2 \sum_{2 \leq s \leq n/2} \binom{n}{s} \exp\left(-\frac{\tau^2 s\bar{p}}{2}\right) \leq 2 \sum_{2 \leq s \leq n/2} \exp\left(s + s \log n - s \log s - \frac{\tau^2 |S||\bar{S}|p}{2}\right) \leq 2 \sum_{2 \leq s \leq n/2} \exp\left(s \log n - \left(1 + \frac{1 - \log s}{\log n} - \frac{\gamma \tau^2}{4}\right)\right) \leq 2 \sum_{2 \leq s \leq n/2} \exp(-\varepsilon_1 s \log n) \leq 4n^{-2\varepsilon_1}.
\]

Note that, if \( |S| \leq \varepsilon_1 n \) or \( |\bar{S}| \leq \varepsilon_1 n \), by our choice of \( \tau, \varepsilon_1 \) and \( \varepsilon_2 \),

\[
(1-\tau)|S||\bar{S}|p \geq (1-\tau)2(1-\varepsilon_1)np \geq 1.5(1+\varepsilon_2)np.
\]

If \( |S| \geq \varepsilon_1 n \) and \( |\bar{S}| \geq \varepsilon_1 n \), then for sufficiently large \( n \),

\[
(1-\tau)|S||\bar{S}|p \geq (1-\tau)\varepsilon_1^2 n^2 p > 2(n-1)p \geq 1.5(1+\varepsilon_2)np.
\]

So it suffices to show that \( \delta^{in} \leq (1+\varepsilon_2)np \) with probability at least \( 1-n^{-\varepsilon} \). This follows immediately from the fact that, by Chernoff’s inequality (Theorem 3.1), the total number of arcs in the random digraph satisfies \( |A| \geq (1+\varepsilon_2)n(n-1)p \) with probability at most \( \exp(-\varepsilon_2^2 n^2 - (\varepsilon_2^2 n^2 - 2)n-1)p/2 \).

Now assume that \( 1+\psi \leq \gamma(n) \leq 100 \). By Corollary 3.6, there exist \( \alpha_1(n), \alpha_2(n) \) and a constant \( x_1 > 0 \) such that

\[
x_1 < \alpha_1(n) < \alpha_2(n) < 1, \quad \alpha_2(n) - \alpha_1(n) \leq x_1/7
\]

and

\[
\alpha_1 pn \leq \delta^{in} \leq \alpha_2 pn \quad \text{and} \quad \alpha_1 pn \leq \delta^{out} \leq \alpha_2 pn.
\]

Let \( \zeta > 0 \) and \( C_1 > 0 \) be given by Lemma 3.18 applied to \( \phi = x_1/7 \) and \( f(n) = \gamma(n) \log n \). Let also \( C_2 \) be given by Lemma 3.17 for \( \zeta \) and \( f(n) \).

Fix \( S \subseteq [n] \). If \( |S|, |\bar{S}| \geq \zeta n \), by Lemma 3.17, \( d^{in}(S) = \frac{|A(S, \bar{S})|}{n^2} \geq (\zeta^2/2)n^2 p \geq 1.5np \geq 1.5\delta^{in} \) with probability at least \( 1-n^{-C_2} \) for sufficiently large \( n \). If \( 2 \leq |S| < \zeta n \), by Lemma 3.18, with probability at least \( 1-e^{-C_1(\gamma \log n)^2} \), for sufficiently large \( n \),

\[
d^{in}(S) = \sum_{v \in S} d^{in}(v) - |A(S)| \geq \delta^{in}|S| - \phi np|S|
\]

\[
\geq \delta^{in}|S| - \alpha_1 np|S|/7 \geq 6\delta^{in}|S|/7 \geq 1.5\delta^{in}.
\]
If $|\bar{S}| \leq \zeta n$, then

$$d^{out}(\bar{S}) = \sum_{v \in \bar{S}} d^{out}(v) - |A[\bar{S}]| \geq \delta^{out}|\bar{S}| - \phi np|\bar{S}|$$
\hspace{1cm} (20)

$$\geq |\bar{S}| np(\alpha_1 - \phi) \geq 1.5np\alpha_2 \geq 1.5\delta^{in}$$
\hspace{1cm} (21)

since $2(\alpha_1 - \phi) > 1.5(\alpha_1 + \phi) \geq 1.5\alpha_2$, and the result follows since $d^{in}(S) = d^{out}(\bar{S})$. □

The next lemma will be useful, when we apply Theorem 1.4 to subpartitions with a very large class, namely subpartitions where one part contains a $(1 - \varepsilon)$-fraction of the vertex set.

**Lemma 3.20.** There exist positive constants $\phi$ and $\psi$ such that the following holds. For any function $g = g(n)$ such that $0 \leq g(n) = o(\log n)$, there exist positive constants $\varepsilon > 0$, $n_0 > 0$ and $C > 0$ such that, for any $p = p(n) \in [(\log(n) - g(n))/(n - 1), (\log(n) + g(n))/(n - 1)]$, with probability at least $1 - n^{-C}$, there is no partition $(X, Y, Z)$ of $[n]$ of the vertex set of $\mathcal{D}(n, p)$ satisfying the following conditions:

(i) $|X| \geq (1 - \varepsilon)n$,

(ii) $|Y| \geq |Z|$ or $|Z| \leq \phi p(n - 1)$,

(iii) $d^{in}(X) + d^{in}(Y) \leq \psi p(n - 1)|Y|$.

**Proof.** Let $\phi \leq 3/400$ and $\psi < 3/20$. Let $\zeta > 0, C_1 > 0$ be obtained by Lemma 3.18 with $f(n) = \log n - g(n)$ and $\phi$. Let $\varepsilon \leq \zeta$ and let $(X, Y, Z)$ be a partition of $[n]$ satisfying the conditions of the lemma. By Lemma 3.3(iv) with $\alpha = 0.09$ and $\varphi = 1.1$, we have, for $n$ sufficiently large, with probability at least $1 - n^{-0.02}$, that $d^{in}(v) + d^{out}(v) \geq 0.18(n - 1)p$ for all $v \in B_y$. Lemma 3.18, we have that $|A[Y]| \leq \phi(n - 1)p|Y|$ and $|A[Y \cup Z]| \leq \phi(n - 1)p(|Y| + |Z|)$ with probability at least $1 - n^{-C_1}$. Thus,

$$d^{in}(X) + d^{in}(Y) = \sum_{v \in Y} (d^{in}(v) + d^{out}(v)) = |A[Y]| - |A(Y, Z)| + |A(Z, X)|.$$

$$\geq 0.18(n - 1)p|Y| - 2\phi(n - 1)p|Y| - \max\{|A[Y \cup Z]|, |Y||Z|\}$$

$$\geq 0.18(n - 1)p|Y| - 2\phi(n - 1)p|Y| - 2\phi np|Y|$$

$$\geq 0.15(n - 1)p|Y|,$$

as required. □

In the next two lemmas, we bound $d^{in}(S)$ in the range $p \sim \log n/(n - 1)$.

**Lemma 3.21.** Let $g = g(n)$ be a function such that $0 \leq g(n) = o(\log n)$. There exist positive constants $\eta > 0, n_0 > 0$ and $\beta > 0$ with the following properties. For all $n > n_0$ and all functions $(\log n - g(n))/(n - 1) \leq p = p(n) \leq (\log n + g(n))/(n - 1)$, with probability at least $1 - n^{-\beta}$, there are at least two vertices with in-degree zero or there is no $S \subseteq [n]$ with size $2 \leq |S| \leq \eta n$ such that $d^{in}(S) < \max\{\delta^{in} + 1, 2\delta^{in}\}$.

**Proof.** Let $p = p(n)$ be a function as in the statement of the lemma and let $\varepsilon > 0$ and $C_1$ be obtained through Lemma 3.9 with $\varphi = 1.1$. By Corollary 3.4 we have $\delta^{in} = o(\log n)$ a.a.s.. Let $\eta = \zeta > 0$ given by Lemma 3.18 applied to $\phi \leq \varepsilon/16$. Assume that the random
digraph has at most one vertex with in-degree zero and fix $S \subseteq [n]$ with size $2 \leq |S| \leq \eta n$. By Lemma 3.18, $|A[S]| \leq \varepsilon n|S|p/16$. Let $S_\ell$ denote the $\varepsilon$-in-light vertices in $S$ and let $S_h = S \setminus S_\ell$.

First assume that all vertices in $S$ are $\varepsilon$-in-light. By Lemma 3.9, with probability at least $1 - n^{-C_1}$, no pair of $\varepsilon$-in-light vertices are adjacent, and thus $d^\text{in}(S) \geq |S|\delta^\text{in} \geq 2\delta^\text{in} \geq \delta^\text{in} + 1$ if $\delta^\text{in} > 0$. If $\delta^\text{in} = 0$, because there is a single vertex with $d^\text{in}(v) = 0$, we have $d^\text{in}(S) \geq |S| - 1 \geq 1 = \max\{2\delta^\text{in}, \delta^\text{in} + 1\}$. Next suppose that there is at least one vertex $u$ in $S$ that is not $\varepsilon$-in-light. Note that $d^\text{in}(u) \geq \delta^\text{in} + \varepsilon np$, which implies that, for $|S| < \varepsilon np/2$, we have $d^\text{in}(S) \geq |A(S, u)| \geq d^\text{in}(u) - |S| + 1 \geq \delta^\text{in} + \varepsilon np/2 \geq 2\delta^\text{in} + 1$ for large $n$. So we can assume that $|S| \geq \varepsilon np/2$.

If $|S_h| \geq |S|/8$, then $d^\text{in}(S) \geq \sum_{v \in S_h} d^\text{in}(v) - |A[S]| \geq |S|\varepsilon np/8 - \varepsilon np|S|/16 \geq \varepsilon(n - 1)p/2 \geq 2\delta^\text{in} + 1$. So assume that $|S_h| \leq |S|/8$. Thus, $|S_\ell| \geq 7|S|/8$. Then $d^\text{in}(S) \geq \delta^\text{in}|S_\ell| - |S_h|$ since no pair of $\varepsilon$-in-light vertices have a common in-neighbour by Lemma 3.9. If $\delta^\text{in} > 0$, then $d^\text{in}(S) \geq |S_\ell| - |S_h| \geq 3\varepsilon(n - 1)p/8 \geq 2\delta^\text{in} + 1$. So assume that $\delta^\text{in} = 0$. Since there is a single vertex with in-degree zero, we have $d^\text{in}(S) \geq |S_\ell| - 1 - |S_h| \geq \varepsilon(n - 1)p/4 \geq 2\delta^\text{in} + 1$. 

\[\text{Lemma 3.22.}\] Let $\phi > 0$ be a constant and $g = g(n)$ be a function such that $0 \leq g(n) = o(\log n)$. There exist positive constants $\eta > 0$, $n_0 > 0$ and $\beta > 0$ such that the following holds for all $n > n_0$ and all functions $(\log n - g(n))/(n - 1) \leq p = p(n) \leq (\log n + g(n))/(n - 1)$. With probability at least $1 - n^{-\beta}$, there exist two vertices with in-degree zero or there is no $S \subseteq [n]$ with size $\phi \log n \leq |S| \leq \eta n$ such that $d^\text{out}(S) < 2\delta^\text{in} + 1$.

\[\text{Proof.}\] Let $\phi > 0$ be a constant. Let $p = (\log(n) + h(n))/(n - 1)$ such that $|h(n)| \leq g(n)$ and let $\varepsilon > 0$ and $C_1$ be obtained through Lemma 3.9 with $\varepsilon = 1$. We may assume that $\phi < \varepsilon/16$. By Corollary 3.4 we have $\delta^\text{in} = o(\log n)$ a.a.s. Let $\eta = \zeta > 0$ and $C_2$ from Lemma 3.18 applied to $\phi$ and let $\psi \leq \phi/2$.

If $h(n) < -\log(\psi \log n)$, at least two vertices have in-degree zero a.a.s. by Chernoff’s inequality (Theorem 3.1), so we consider the case $h(n) \geq -\log(\psi \log n)$.

Assume that at most one vertex has in-degree zero and fix $S \subseteq [n]$ with size $\phi \log n \leq |S| \leq \eta n$. By Lemma 3.18, $|A[S]| \leq \varepsilon n|S|p/16$ with probability at least $1 - n^{-C_2}$. Let $S_\ell$ denote the $\varepsilon$-out-light vertices in $S$ and let $S_h = S \setminus S_\ell$. If $|S_h| \geq |S|/8$, then $d^\text{out}(S) \geq \sum_{v \in S_h} d^\text{out}(v) - |A[S]| \geq |S|\varepsilon np/8 - \varepsilon np|S|/16 \geq 2\delta^\text{out} + 1$. So assume that $|S_h| \leq |S|/8$, and thus $|S_\ell| \geq 7|S|/8$. Then $d^\text{out}(S) \geq \delta^\text{out}|S_\ell| - |S_h|$ since no pair of $\varepsilon$-out-light vertices have a common out-neighbour. We may assume that $\delta^\text{out} = 0$. Indeed, if $\delta^\text{out} > 0$, then $d^\text{out}(S) \geq |S_\ell| - |S_h| \geq (3/8)\varepsilon(n - 1)p \geq 2\delta^\text{in} + 1$.

We first estimate the number of vertices with out-degree zero. The expected number of vertices with out-degree zero is $n(1 - p)^{n-1} = \exp(-h(n) + o(1))$. It is obvious that the smaller is $h(n)$, the higher is the number of vertices with out-degree zero. If $h(n) = -\log(\psi \log n)$, then the expected number of vertices with out-degree zero is equal to $\psi \log n(1 + o(1))$. Thus, by Chernoff’s inequality (Theorem 3.1), there exists $\beta > 0$ such that the probability that there are more than $5\phi \log n/8$ vertices with out-degree zero is at most $\exp(-\beta \log n)$. Then, $d^\text{out}(S) \geq |S_\ell| - (5\phi/8) \log n - |S|/8 \geq 3|S|/4 - 5\phi \log n/8 \geq 2\delta^\text{in} + 1$ for $h(n) \geq -\log(\psi \log n)$.

\[\hfill\]
4 Proof of Theorem 1.3

In the proof of Theorem 1.3, we will need to consider five different probability regimens, which are described in the following result.

Lemma 4.1. Let \( p = p(n) \in [0, 1] \). If

(i) \( p \leq (\log(n) - g(n))/(n - 1) \), for a function \( g(n) = \omega(1) \) and \( g(n) = o(\log n) \); or

(ii) \( (\log(n) - g(n))/(n - 1) \leq p \leq (\log(n) + g(n))/(n - 1) \), for a function \( g(n) = \omega(1) \) and \( g(n) = O(\log n \log n) \); or

(iii) \( (\log(n) - g(n))/(n - 1) \leq p \leq (\log(n) + g(n))/(n - 1) \), for a function \( g(n) = \Omega(\log \log n) \) and \( g(n) = o(\log n) \); or

(iv) \( p \sim (1 + \psi) \log(n)/(n - 1) \), for a constant \( \psi > 0 \); or

(v) \( p = g(n) \log(n)/(n - 1) \), for a function \( g(n) = \omega(1) \),

then \( \tau(\mathcal{D}(n, p)) = \lambda(\mathcal{D}(n, p)) \) a.a.s.

We will now show how Theorem 1.3 follows from the lemma above. Let \( p = p(n) \in [0, 1] \). Let \( A \) be the event that \( \tau(\mathcal{D}(n, p)) = \lambda(\mathcal{D}(n, p)) \) and let \( \bar{A} \) denote the complement of \( A \). We wish to show that \( \Pr(\bar{A}) = o(1) \). We will use the subsequence principle. Thus, let \( (n_i)_{i \in \mathbb{N}} \) be an arbitrary increasing sequence. We need to show that there is a subsequence of \( (n_i)_{i \in \mathbb{N}} \) such that \( \Pr(\bar{A}) \) converges to 0 in that subsequence.

Let \( h(n) = (n - 1)p/\log n \). Then there exists a subsequence of \( (n_i)_{i \in \mathbb{N}} \) such that \( h(n_i) \to c \), where \( c \) is a nonnegative constant or \( \infty \). If \( c < 1 \), we have that \( \Pr(\bar{A}) = o(1) \) for this subsequence by Lemma 4.1(i). If \( c = 1 \), we have that \( \Pr(\bar{A}) = o(1) \) for this subsequence by Lemma 4.1(ii) and (iii). If \( 1 < c < \infty \), we have that \( \Pr(\bar{A}) = o(1) \) for this subsequence by Lemma 4.1(iv). If \( c = \infty \), we have that \( \Pr(\bar{A}) = o(1) \) for this subsequence by Lemma 4.1(v).

Proof of Lemma 4.1. Case (i): Suppose that \( p \leq (\log(n) - g(n))/(n - 1) \), for a function \( g(n) = \omega(1) \) and \( g(n) = o(\log n) \). If we have two vertices with in-degree 0, then \( \tau = \lambda = 0 \). The expected number of vertices with in-degree 0 is \( n(1 - p)^{n - 1} \geq \exp(g(n) + o(1))(n - 1) \to \infty \). So, by Chernoff’s inequality (Theorem 3.1), there are at least two vertices with in-degree 0 a.a.s.

For the remaining cases, let \( \mathcal{P} = (V_0, \ldots, V_t) \) be a partition of \( [n] \). We need to show that \( \sum_{i=1}^t d^n(V_i) \geq \lambda(t - 1) \), since this is equivalent to proving that \( \tau(\mathcal{D}(n, p)) \geq \lambda(\mathcal{D}(n, p)) \) by Theorem 1.4.

Cases (ii) and (iii): Let \( \phi > 0 \) and \( \varepsilon > 0 \) be obtained by Lemma 3.20. Fix \( \eta_1 > 0 \) as in Lemma 3.21 and let \( \eta_2 > 0 \) be obtained by applying Lemma 3.22 to \( \phi \). Let \( \alpha = \min\{\varepsilon, \eta_1, \eta_2\} \). We may assume that the number of vertices with in-degree zero is at most one, otherwise \( \tau = \lambda = 0 \) trivially.

Suppose first that there exists \( j > 0 \) such that \( |V_j| \geq (1 - \alpha)n \). Let \( B = \bigcup_{i > 0, i \neq j} V_i \). Note that the result is trivial if \( B = \emptyset \), as \( t - 1 = 0 \) in this case, thus suppose \( |B| > 0 \). If \( |V_0| \leq \phi np \) or \( |V_0| \leq |B| \), then \( d^n(V_j) + d^n(B) = \Theta(p(n - 1)|B|) \) by Lemma 3.20.
Since \( \lambda = O(\delta^n) \) by Lemmas 3.14 and 3.15 and \( \delta^n = o(\log n) \) by Corollary 3.4, we have \( d^n(V_j) + d^n(B) = \omega(\lambda |B|) \), so that

\[
\sum_{i=1}^{t} d^n(V_i) \geq d^n(V_j) + d^n(B) \geq \lambda |B| \geq \lambda (t-1).
\]

So assume that \( |V_0| > \phi np \) and \( |V_0| > |B| \geq 1 \). Let \( I = \{i > 0 : |V_i| = 1, \ d^n(V_i) \leq \lambda \} \). Observe that \( d^n(V_j) = d^{out}(V_0 \cup B) \) and by Lemma 3.22 we have \( d^n(V_j) \geq d^{out}(V_0 \cup B) \geq 2\delta^n + 1 \), which is at least \( \lambda \) a.a.s. Moreover, for every \( V_i \in P \setminus I \) for \( i \neq j \), by Lemma 3.21, \( d^n(V_i) \geq \max\{\delta^n + 1, 2\delta^n\} \), which is at least \( \lambda \) a.a.s. Let \( V(I) = \bigcup_{i \in I} V_i \). Then we have

\[
\sum_{i=1}^{t} d^n(V_i) \geq \lambda (t - |I|) + \sum_{i \in I} d^n(V_i) = t\lambda - \sum_{v \in V(I)} (\lambda - d^n(v)) \geq t\lambda - \lambda,
\]

by the definition of \( \lambda \).

Next suppose that \( |V_i| \leq (1 - \alpha)n \) for all \( i > 0 \). If \( 2 \leq |V_i| \leq \alpha n \), then \( d^n(V_i) \geq \max\{\delta^n + 1, 2\delta^n\} \) by Lemma 3.21 and \( d^n(V_i) \geq \lambda \) a.a.s. by Lemmas 3.14 and 3.15. If \( |V_i| \geq \alpha n \), we have \( |V_i| \geq (1 - \alpha) n \) and so, by Lemma 3.17, \( d^n(V_i) = |A(V_i, V_i)| \geq \zeta^2 n^2 p/2 \geq \lambda \) for \( \zeta = \min\{\alpha, 1 - \alpha\} \). Thus, a.a.s.

\[
\sum_{i=1}^{t} d^n(V_i) \geq \lambda (t - |I|) + \sum_{i \in I} d^n(V_i) \geq t\lambda - \lambda,
\]

again by the definition of \( \lambda \).

Case (iv): By Lemma 3.19, every set \( S \subseteq [n] \) of size in \([2, n - 2]\) has \( d^n(S) \geq 1.5\delta^n \) a.a.s. By Lemma 3.13 we have \( \lambda \sim \delta^n \) a.a.s., which implies that \( d^n(S) \geq \lambda \). Let \( I = \{i > 0 : |V_i| = 1, \ d^n(V_i) \leq \lambda - 1 \} \). If \( |V_i| \leq n - 2 \) for all \( i \), then a.a.s. \( d^n(V_i) \geq \lambda \) for all \( i \in I \) and so

\[
\sum_{i=1}^{t} d^n(V_i) \geq \lambda (t - |I|) + \sum_{i \in I} d^n(V_i) \geq t\lambda - \lambda,
\]

by the definition of \( \lambda \).

Now suppose, without loss of generality, that \( |V_1| = n - 1 \) (the case \( |V_1| = n \) is trivial). Then there is a single vertex \( v \notin V_1 \). We can assume that \( t = 2 \) since the case \( t = 1 \) is trivial. Thus, \( V_2 = \{v\} \) and \( d^n(V_1) + d^n(V_2) = d^n(v) + d^{out}(v) \geq \delta^n + \delta^{out} \).

By Corollary 3.6 we have \( \delta^n + \delta^{out} \geq 1.5\delta^n \) a.a.s. By Lemma 3.13, we conclude that \( d^n(V_1) + d^n(V_2) \geq 1.5\delta^n \geq \lambda \) a.a.s.

Case (v): We may proceed as in the previous case, since, for every \( S \subseteq [n] \) of size in \([2, n - 2]\), we again have \( \delta^n \sim \lambda \) and \( d^n(S) \geq 1.5\delta^n \geq \lambda \) a.a.s. (since \( \delta^n \sim (n - 1)p \) a.a.s. by Lemma 3.10 and \( \lambda \sim (n - 1)p \) a.a.s. by Corollary 3.16). This leads to the desired result with the above arguments if \( |V_i| \leq n - 2 \) for every \( i \). Otherwise, we use Lemma 3.10 to show that \( \delta^n + \delta^{out} \geq 1.5\delta^n \) a.a.s., and we may again repeat the analysis of the previous case.
