Background: The complexity of surgical interventions has major implications for the design of RCTs. Trials need to consider how and whether to standardize interventions so that, if successful, they can be implemented in practice. Although guidance exists for standardizing non-pharmaceutical interventions in RCTs, their application to surgery is unclear. This study reports new methods for standardizing the delivery of surgical interventions in RCTs.

Methods: Descriptions of 160 surgical interventions in existing trial reports and protocols were identified. Initially, ten reports were scrutinized in detail using a modified framework approach for the analysis of qualitative data, which informed the development of a preliminary typology. The typology was amended with iterative sequential application to all interventions. Further testing was undertaken within ongoing multicentre RCTs.

Results: The typology has three parts. Initially, the overall technical purpose of the intervention is described (exploration, resection and/or reconstruction) in order to establish its constituent components and steps. This detailed description of the intervention is then used to establish whether and how each component and step should be standardized, and the standards documented within the trial protocol. Finally, the typology provides a framework for monitoring the agreed intervention standards during the RCT. Pilot testing within ongoing RCTs enabled standardization of the interventions to be agreed, and case report forms developed to capture deviations from these standards.

Conclusion: The typology provides a framework for use during trial design to standardize the delivery of surgical interventions and document these details within protocols. Application of this typology to future RCTs may clarify details of the interventions under evaluation and help successful interventions to be implemented.

Introduction

Surgery has recently been recognized as a complex healthcare intervention1–4. Complex interventions comprise multiple interacting components that may be accompanied by concomitant interventions (or co-interventions), including anaesthesia and elements of preoperative and postoperative care2. This complexity can create challenges during the design of surgical interventions in RCTs, in terms of establishing standards of surgery and monitoring whether interventions are delivered as intended. This is exemplified in a recent systematic review5 of 80 RCTs, reporting details of 160 surgical interventions, which found that only 47 (29.4 per cent) were reported to be standardized in some way, and monitoring of adherence to the intervention was similarly poor. These issues have partly been addressed through the publication of the SPIRIT6 and TIDieR7 guidance. The SPIRIT statement provides a checklist of 33 items to be reported in trial protocols. Items relating to interventions (11a–d) recommend that the trial protocol provides information about ‘each group with sufficient detail to allow replication’ and ‘procedures for monitoring adherence to intervention protocols’. The TIDieR guidance – an extension of item 11 of
SPIRIT – comprises 12 items relating to the description of all types of intervention, and recommends that the duration, dose and materials used in the intervention are provided.

Although SPIRIT and TIDieR represent important progress for the design and reporting of interventions within RCTs, these guidance documents are not specific for, or easily applicable to, surgical interventions. For example, there is no such thing as a ‘dose’ of a surgical intervention and surgery cannot typically be delivered in an identical manner multiple times. It is difficult, therefore, to know how these recommendations should be used and applied during the design of RCTs in surgery, meaning that the optimal way of describing surgical interventions remains uncertain. The aim of this study was to develop new methods for standardizing and monitoring surgical interventions within RCTs in surgery.

Methods

Development of the typology

The typology – defined as a system used for grouping or classifying items according to how they are similar – was informed by a detailed systematic review of how surgical interventions are described, standardized and monitored in published RCTs. Briefly, RCTs in surgery, published between 2010 and 2011, were identified by hand-searching online archives of the top six journals ranked by impact factor for each of general medicine and surgery. Included were trials in any surgical specialty evaluating a surgical intervention. This was defined as trials that involve physically changing body tissues and organs through manual operation such as cutting, abrading, suturing or the use of lasers. Where available, trial protocols were obtained for each study and analysed in the same way as full-text articles.

A detailed analysis of the included RCTs and protocols was undertaken using a modified framework approach for the analysis of qualitative data. Framework analysis is usually a deductive approach used to analyse content by assigning descriptive labels, which are outlined a priori and collectively comprise a framework. In this study, it was not possible to assign labels a priori, and the process was therefore modified such that a subset of ten papers were read and reread to understand the data and develop a preliminary framework. Remaining trial reports were read sequentially and, where required, existing categories were amended or removed, and additional elements added. This iterative process of testing the framework was repeated independently by two researchers until all included papers had been assessed. Once all studies and protocols had been reviewed, a meeting with the research team was held to discuss the proposed typology. Following this, the typology was modified (1 category was added and some existing categories were rephrased). Subsequently, all papers were reassessed with the updated typology to ensure that every description was accounted for.

Results

Typology for designing surgical interventions in RCTs

A total of 80 RCTs evaluating 160 interventions within a range of surgical subspecialties were identified (Fig. S1, supporting information). Of the 160 interventions, at least some textual description of the surgical intervention (beyond its name) was provided for 118 (73.8 per cent) and this informed the typology. The typology is divided into three sections relating to the description, standardization and monitoring of surgical interventions (Fig. 1). The final part of the paper demonstrates how a trial protocol for surgical interventions can be designed using the typology, illustrating this with worked examples.
of a surgical intervention are the creation and closure of an incision (two components).

Identification of individual steps of interventions
Detailed analysis of the components of surgical interventions identified that there are steps within each component, representing the precise details within a component. For example, making an incision (1 component) involves several individual details including its location, length, direction and depth. The number and type of steps within any component may be large and wide-ranging, and vary between interventions. It is therefore not possible to propose a uniform typology for the steps of surgical interventions. Steps can be identified for each intervention once the technical purpose and the constituent components have been established.

It is recommended that descriptions of surgical interventions are considered at three levels in trial protocols: the
overall intervention, its components, and steps within each component. Examples are provided in Table 2. Initially, establishing all three levels of description of each intervention is necessary. This detailed intervention description can then be used to consider how interventions (and their components and steps) might be standardized (section 2) and monitored (section 3) – if at all – within an RCT.

**Section 2: Standardization of surgical interventions**

In an RCT, it is critical to decide whether a surgical intervention needs to be standardized, and how this should be done. Standardization refers to whether the trial protocol specifies exactly how an intervention should be delivered, and may inherently necessitate monitoring during the trial to establish whether centres and surgeons actually followed these instructions. There are several factors that might influence intervention standardization, such as the overall trial design (for example pragmatic versus explanatory) or the developmental stage of the intervention. For surgical interventions, it is recommended that three aspects of standardization are considered for each component and step: the type of standardization, conditions relating to it, and the flexibility of delivery. These factors should all be set out clearly in the protocol to inform trial conduct, monitoring and reporting of what was delivered during the trial.

**Types of standardization**

The type of standardization required for each component and step of an intervention may be classified as mandated, prohibited or optional. A mandatory step, for example, would be essential to perform in all interventions (and if not performed constitutes a deviation from the protocol), whereas the opposite is true if a step is prohibited. An optional component or step is one that may or may not be performed, at the discretion of each participating surgeon.

**Conditions relating to standardization**

During trial design, trialists should identify clinical findings or conditions that may influence the type of standardization required, and detail them in the trial protocol so it is clear what action to take when they are encountered. For example, it may be necessary to decide whether to undertake a cholecystectomy at the same time as a bariatric procedure. A trial protocol therefore needs to describe the conditions relating to this clinical situation: for example, a concomitant cholecystectomy may be mandated only among patients with symptomatic gallstone disease (that is, under certain conditions) and prohibited in other patients.

**Flexibility of standardization**

A range of flexibility is possible, so that a component or step can be delivered exactly as described within the protocol, within boundaries or totally flexibly. For example, a trial protocol may require surgeons to create an anastomosis using 4-0 polypropylene (exactly as described), any 4-0 or 5-0 monofilament suture (within boundaries) or simply state that this can be performed according to their own preference (totally flexible).

**Section 3: Monitoring of surgical interventions during the trial**

Monitoring how surgical interventions are actually delivered in a trial (fidelity) is essential to inform the interpretation of results and subsequent implementation of interventions in practice. Three possibilities for recording and reporting fidelity were identified: the intervention, component or step is not delivered at all; an intervention, component or step from another trial group is delivered instead; or an entirely different intervention, component or step is delivered (Table 3). Additionally, the reasons for which the above deviations occur may be crucial and it is therefore recommended that trialists consider recording these throughout the RCT.

**Example of how the typology can be applied to surgical RCTs**

The typology was used to design the interventions in two surgical RCTs, and subsequently report these details in the trial protocols. The Rescue-ASDH (Randomized Evaluation of Surgery with Craniectomy for patients Undergoing Evacuation of Acute SubDural Haematoma) trial compares the effectiveness and cost-effectiveness
### Table 3  Levels and types of intervention fidelity

| Level of fidelity | Types |
|-------------------|-------|
| Deviation from intended intervention | Did not receive any intervention  |
| | Received intervention in other trial arm  |
| | Received an alternative intervention not being evaluated in the trial  |
| Deviation from component(s) of the intended intervention | Did not receive the component |
| | Component delivered according to description in other trial arm |
| | Received an alternative component, or component performed in a different way |
| Deviation from step(s) within component(s) of the intended intervention | Step not done |
| | Step from other trial arm performed |
| | Different step performed, or step performed in a different way |

### Table 4  Standardization of laparoscopic Roux-en-Y gastric bypass in the By-Band-Sleeve study

| Components and steps | Laparoscopic Roux-en-Y gastric bypass | Description provided in trial protocol* | Adherence during trial (n = 75) |
|----------------------|---------------------------------------|----------------------------------------|-------------------------------|
| Incision and access  | Establishment of pneumoperitoneum      | Procedures will be undertaken laparoscopically. Methods used to create a pneumoperitoneum, and the placement of laparoscopic ports and retractors, are at the discretion of the surgeon | 75 (100) |
|                      | Insertion of additional ports          | Mandatory None Veress/open technique Flexible | |
|                      | Dissection                             | The pouch can be created according to surgeons' usual practice, although a horizontal gastric pouch that includes fundus is prohibited | 75 (100) |
|                      | Creation of a horizontal pouch         | Prohibited n.a. n.a.                      | |
|                      | Re却ion                               | Measurement of the biliary limb Mandatory None Maximum 75 cm 120 (100–150)* 30 (3–60)* | |
|                      | Measurement of the gastric limb        | Mandatory None Maximum 150 cm 120 (100–150)* 150 cm respectively are recommended | |
|                      | Opening of the retrocolic window       | Optional None Flexible Routing of the Roux limb (antecolic or retrocolic) is flexible | Antecolic 21 (28) Retrocolic 54 (72) |
|                      | Anastomoses                            | Mandatory None Sutured/stapled, 1–2 layers, oral route or intra-abdominal | Stapled 75 (100) Circular 10 (13) Linear 65 (87) |
|                      | Gastrojejunostomy                      | Sutured/stapled, 1–2 layers, oral route or intra-abdominal Anastomoses can be performed as the surgeon chooses (e.g. stapled or sutured, circular or linear, single or double layer) | Stapled 75 (100) Triple 25 (33) Single 50 (67) |
|                      | Jejunojejunostomy                      | Sutured/stapled, 1–2 layers | |
|                      | Closure                                | Optional None Flexible Closure of mesenteric defects is optional | 59 (79) 58 (77) 54 (100)† |
|                      | Closure of mesenteric defects           | Optional None Flexible Use of a bougie is optional | 66 (88) |
|                      | Peterson’s space                       | | |
|                      | Jejunojejunostomy                      | | |
|                      | Mesocolon                             | | |
|                      | Other                                  | | |

Values in parentheses are percentages unless indicated otherwise; *values are median (i.q.r.). †Only retrocolic reconstructions were included in the denominator, because a mesocolonic window is not created during antecolic bypasses. n.a., Not applicable.
of craniotomy and decompressive craniectomy for acute subdural haematoma. The By-Band-Sleeve study\textsuperscript{17} compares the effectiveness of laparoscopic adjustable gastric band, Roux-en-Y gastric bypass and laparoscopic sleeve gastrectomy for patients with severe and complex obesity. In conjunction with two of the present researchers and the trial teams, the typology was used to consider the overall purpose of these interventions and to identify the constituent components and steps. Subsequently, the degree of standardization required for each was established. Both are multicentre pragmatic RCTs and all interventions are undertaken routinely within clinical practice. It was therefore agreed that only the key intervention components needed to be standardized, in order to distinguish the interventions in each trial group from one another.

As an example, Table 4 lists the components and steps of laparoscopic Roux-en-Y gastric bypass (which has a purpose of reconstruction), and the degree of standardization required for each step. The agreed intervention description (as detailed within the trial protocol) is also provided, together with information about fidelity to each aspect of this description. Standardization of the interventions in the Rescue-ASDH trial (undertaken by surgeons and trialists independent of the typology research team) is described in Tables S1 and S2 (supporting information).

**Discussion**

This study describes a novel framework (a typology) for describing surgical interventions in RCTs. It provides guidance on how to consider the extent of intervention standardization in trial protocols, and subsequent monitoring during the trial itself. The typology requires that the overall purpose of an intervention is described, and that it is deconstructed into constituent components and steps. The deconstructed trial intervention then provides a platform to inform the level of standardization of each component and step to be delivered and monitored within the trial. These factors can be discussed and agreed during trial design (potentially as part of pretrial pilot work), so that details for undertaking the surgical interventions can be provided within the main trial protocol, and subsequently monitored during the trial itself. The typology will help to clarify exactly how interventions were intended to be delivered within RCTs and allow the trialists to monitor adherence to this. Application of the typology to RCTs in surgery has the potential to improve trial conduct, and better to inform the implementation of successful interventions in clinical practice.

It may not always be necessary or appropriate to standardize each component or step of a surgical intervention. This should be driven by the research question, the interventions being compared (including the expertise of those delivering them) and whether the trial is predominantly explanatory or pragmatic\textsuperscript{15}. In explanatory trials, which determine the efficacy of interventions, great detail may be necessary because the interventions are often novel and their safety needs to be assessed within carefully controlled settings. Pragmatic trials, which determine whether interventions are effective in the real world, are often multicentre studies with large numbers of surgeons. Under such circumstances, specifying each operative step (and those of all accompanying co-interventions) is likely to create difficulties, and ensuring that each step was delivered as planned may be unrealistic. A balance between adequate standardization and practicality is therefore necessary and appropriate. One way of achieving this is to determine the minimum active ingredients of the intervention\textsuperscript{18} – those that are thought to optimize outcomes or those that are different between the interventions in each trial group – and the degree to which they need to be standardized. In this way, monitoring only the key components may be sufficient, rather than monitoring all components and steps, in order to ensure the intervention is actually delivered as planned.

A potential limitation of this study is that the typology and its categories may not be fully comprehensive. Although further testing could be undertaken with more trial reports, 80 papers were included, providing a total of 160 interventions. The final framework was applied to all papers, and all of the information regarding each intervention could be classified according to the existing typology. Another limitation is that application of the typology was limited to four surgical interventions across two RCTs. A final limitation is that, although specific to surgery, the typology focuses solely on the intervention itself, meaning that, currently, it will need to be used in conjunction with other guidelines such as TIDieR and SPIRIT. Development of a typology for co-interventions, and identification of the factors that might influence the degree of standardization required (for example explanatory versus pragmatic trials), was beyond the scope of this study, which aimed to derive a classification system from existing literature. Work is ongoing in both of these areas, to develop a comprehensive set of guidelines for surgical RCTs. This will require considerable testing, in both new and ongoing studies, across a variety of different interventions and settings, in order to establish its validity and usefulness.

This typology of surgical interventions provides a framework for deconstructing surgical interventions into their constituent components and steps to ensure that all intervention components are considered apriori. In a pragmatic
trial, after identifying all of the components, those deemed to be key or crucial can be agreed, such that parts requiring standardization are described clearly in the protocol and other components can be delivered according to surgeons’ individual preferences. This will allow distinction between mandatory, prohibited and optional steps of an intervention, as well as those that can be delivered flexibly. This approach will require surgeons to agree on a few key details about how an intervention should be performed and within what boundaries, rather than all of its individual steps. Thus, other elements can be undertaken according to personal preference, removing the need for surgeons to conform to a detailed, universal, operative script. More importantly, engaging surgeons in designing interventions in this way may increase the likelihood that they will accept the results of RCTs in surgery and, if interventions are deemed to be effective, actually implement them in routine practice.
