ABSTRACT
In this paper, the first bio-nanocolloid including manganese oxide nanoparticles and copper nanocomplex in the presence of \textit{Amaranthus spinosus} as one unwanted plant was prepared (Mn\textsubscript{3}O\textsubscript{4}/CuL bio-nanocolloid). As-prepared bio nanocolloid was analysed completely by different techniques such as FT-IR, ICP-AES, SEM, EDX, TEM and elemental analysis to have the size, structure, morphology and elements in this compound. This bio-nanocolloid showed high catalytic activity towards green oxidation reactions of alcohols using hydrogen peroxide under solvent free conditions. The longevity, easy and practical recoverability of the solid catalyst was also confirmed for six times. The natural starting material for a long-term stability catalyst preparation, using ideal oxidant (H\textsubscript{2}O\textsubscript{2}), solventless and easy work up show the great potential in scalability for actual industries applications.

Introduction
Nanocomposites, having several outstanding properties as compared to conventional monolithic materials, are one of the most important classes of the engineered compounds [1]. Their possibilities in tuning the properties of nanocolloid composites gained much importance in different fields commercially and technologically [2–6]. In this regards, chemical synthesis of nanocomposite materials reduces their application in various field because chemical materials can impart toxicity to them. Toxicity related to these kinds of compounds has been directly linked to the use of chemicals as reducing and capping agent [7–12]. Recently, some studies have used less toxic chemical reducing agents, but these studies have used acidic/basic environment or surfactant for their synthesis, which can be toxic to environment and living organisms. Hence, the preparation of nanocolloid composites special metal matrix composites using natural substrates such as plants is becoming popular and attractive day by day to minimum or no use of harmful chemicals [13]. These methods are not only eco-friendly but also less time consuming, cost effective, stable operation, efficient and safer [14–19]. Among plants, weeds are plants that grow where they are not wanted and are therefore bad news to crop farmers. While, they can be very useful for many fields [20–24]. They find various potential applications such as catalysts, solar cells and treatment of water, pharmaceutical industry and Li-air batteries due to their low cost, earth abundance, environmental friendliness and variable oxidation states [25–29].

Oxidation reaction is one of the most important reactions in pharmaceutical industries [30]. The safety of oxidation systems in large scale can influence on the hesitation to employ. Fuel, energy and oxidant are three factors in reactors for performing oxidation reactions in industry [31]. Hence, green strategies attract so much attention as economical and environmental point of view. Oxidation of alcohols to aldehydes, esters and carboxylic acids, and ketones are one of the most essential chemical processes in both academic and industrial research, because alcohols can transfer to valuable products for pharmaceuticals, dyestuffs, agrochemicals and fragrances industries [31–34]. Many applied homogeneous catalysts for these reactions created many challenges from the environmental point of view. Hence, increasing efforts have been devoted in developing heterogeneous catalysts. Recently, metal matrix nanocomposites including metal oxides or/and nano transition metal oxide could replace instead of heterogeneous catalyst. Particularly and ideally in aqueous solution, H\textsubscript{2}O\textsubscript{2} is greatly attractive for releasing active oxidative species and producing water as the only by-product. In this context, employing nano metal oxides along with nano-transition metal complex to fabricate efficient catalysts for alcohols oxidation with green oxidant is highly desirable [35].

To reach this goal and in continuing our works on synthesis of novel nanocatalysts for industrial application, we made copper nanocomplex (CuL) and fabricated nanocolloid including CuL nanocomplex based on Mn\textsubscript{3}O\textsubscript{4} nanoparticles using ultrasonic irradiation in the presence of \textit{Amaranthus spinosus} (AS). The catalytic activities of it were considered as a heterogeneous catalyst for selective oxidation of primary and...
secondary alcohols to aldehydes and ketones products, respectively. As practical application point of view, H$_2$O$_2$ was used as ideal oxidant under solvent free conditions.

**Materials and methods**

*Amaranthus spinosus* was collected from Mahmoodabad village, Jiroft, Iran. Cu(NO$_3$)$_2$, 2-hydroxynaphthalene-1-carbaldehyde and manganese nitrate tetrahydrate were purchased from Sigma-Aldrich (St. Louis, MO). 2-Amino pyridine and solvents were provided from Across and Merk Company, Iran, respectively. FT-IR spectra of L ligand, CuL nanocomplex and Mn$_3$O$_4$/CuL bio-nanocolloid were recorded by FT-IR spectrophotometer (NICOLET iS10). X-ray energy-dispersive spectroscopy (EDS) detector (IE 300X, Oxford Semiconductor Co., Ltd., Oxford, UK) attached to the SEM was used for analysis of morphology and percentage of elements in this novel nano-colloid. TEM microscope (Philips CM30, Eindhoven, Netherlands) was employed for observing the shape of it. An ultrasonic bath was used for synthesis of CuL nanocomplex and Mn$_3$O$_4$/CuL bio-nanocolloid (Ultrasonic cleaner 5200iS3 model, SoITEC, Milan, Italy, frequency 40 kHz). XRD patterns of nanocomposite and nanoparticles were determined by Philips Netherland (Eindhoven, Netherlands), X’Pert Pro model. $^1$H NMR and $^{13}$C NMR spectra of ligand were recorded on Varian, UNITYInova 500 MHz. Elemental analysis of ligand was considered by CHSNO, ECS4010, Italy (University of Medical Science, Kerman, Iran).

**Experimental**

**Synthesis of ligand (L)**

Schiff base ligand was obtained by addition of a solution of 2-hydroxynaphthalene-1-carbaldehyde (1.7 g) in ethanol
(40 ml) to a solution of 2-aminopyridine (5 mmol, 0.94 g) in ethanol (40 ml) and the reaction mixture was stirred for 24 h at room temperature. The obtained precipitate was filtered and dried in air. Finally, the product was characterized by IR, $^1$H NMR and $^{13}$C NMR spectroscopy.

$^{C_{16}H_{12}N_2O}_{\text{C}}$: anal. Found: C, 78.69; H, 4.43; N, 12.50; Calc.: C, 77.40; H, 4.87; N, 11.28, IR (KBr, cm$^{-1}$): $\nu_{\text{C}=\text{N}}$, 1472; $\nu_{\text{C}=\text{H}}$, 1608; $^1$H NMR (301 MHz, DMSO-d$_6$) $\delta$ 15.18 (d, J = 7.8 Hz, 1H), 9.81 (d, J = 7.7 Hz, 1H), 8.51 (dd, J = 5.0, 1.9 Hz, 1H), 8.22 (d, J = 8.4 Hz, 1H), 8.04–7.82 (m, 2H), 7.71 (dd, J = 7.9, 1.4 Hz, 1H), 7.59 (d, J = 8.1 Hz, 1H), 7.52 (dd, J = 8.4, 7.0, 1.5 Hz, 1H), 7.37–7.25 (m, 2H), 6.84 (d, J = 9.4 Hz, 1H). $^{13}$C NMR (76 MHz, DMSO) $\delta$ 177.2, 152.8, 150.6, 148.9, 139.2, 133.6, 129.3, 128.7, 126.4, 124.2, 123.9, 121.6, 119.61, 115.2 and 108.0.

Synthesis of copper nanocomplex (CuL)
A solution of L ligand (3 mmol or 0.74 g in 15 ml THF) was poured dropwise under ultrasonic irradiation into THF solution of Cu(NO$_3$)$_2$ (2 mmol or 0.56 g in 10 ml THF). After 12 h, the obtained precipitate was filtered, washed by THF, and dried in the air.

**Synthesis of Mn$_3$O$_4$/CuL bio-nanocolloid (Mn$_3$O$_4$/CuL)**
Four grams of AS to 200 ml of Milli-Q water and heated at 80 °C. After settling for 1 h, the extract was vacuum filtered.

Two hundred millilitres of manganese (II) nitrate tetrahydrate (0.05 M) was added to the extract solution of AS (170 ml) and water (130 ml) at pH = 9 within 10 min at room temperature under ultrasonic irradiation and Mn$_3$O$_4$ nanoparticles was obtained. Then, 200 μl of aqueous solution of CuL (0.01 M) was injected in it and stirred. After 20 min, Mn$_3$O$_4$/CuL bio-nanocolloid was obtained.

**Green oxidation of alcohols using Mn$_3$O$_4$/CuL bio-nanocolloid**
To a mixture of alcohol (2 mmol) and Mn$_3$O$_4$/CuL bio-nanocolloid (0.014 g) under solvent free conditions, 0.8 mmol H$_2$O$_2$ (16 ml) was added and the reaction mixture was stirred at 80 °C for 5 h.
Recycling procedure of Mn₃O₄/CuL bio-nanocolloid on the oxidation of benzyl alcohol

To a mixture of benzyl alcohol (1 mmol, 0.1 ml) and Mn₃O₄/CuL bio-nanocolloid (0.007 g) under solvent free conditions, H₂O₂ was added (0.4 mmol, 8 ml) and the reaction mixture was stirred at 80°C for 5 h. After completion of the reaction, 1 ml ethyl acetate was added and catalyst was separated by centrifugation. Mn₃O₄/CuL bionanocomposite as the isolated solid phase was dried under air and reused for next runs.

Results and discussion

Green Mn₃O₄ nanoparticles were performed by adding manganese salts to extraction solution of AS under ultrasonic irradiation. It should be noted that at pH = 7 of AS, the mixture of MnO₂, Mn₃O₄ and Mn₂O₃ was obtained (Figure 1(a)) [36]. While, Mn₃O₄ nanoparticles were gained at pH = 9 as a sole product (Figure 1(b)). Figure 1(b) shows XRD of Mn₃O₄ exhibiting (211) predominant orientation at 2θ = 36.1° corresponding to tetragonal structure of Mn₃O₄ with I41/amd.
space group and an estimated crystallite size of 40 nm. Other different characterization peaks (112), (200), (103), (004), (220), (105), (321), (224) and (400) were at 28.9, 31, 32.3, 38.11, 44.54, 50.6, 58.78, 59.66 and 64.71°, respectively. The estimated lattice parameters are $a = b = 5.7621$ Å and $c = 9.4696$ Å which are good agreement with previous literature [37]. The same set of characteristic peaks was observed in the XRD pattern of Mn$_3$O$_4$/CuL bio-nanocolloid, which indicates the stability of the crystalline phase of nanoparticles during the synthesis of bio nanocomposite. The average crystallite size Mn$_3$O$_4$/CuL bio-nanocolloid (45 nm) was estimated using the Debye–Scherrer formula. Other peaks were related to CuL nanocomplex.

On the other hand, L ligand was obtained by condensation of 2-hydroxy 1-naphthaldehyde and 2-aminopyridine. By adding copper salt to L ligand under ultrasonic irradiation, water-soluble CuL nanocomplex was achieved. The mixture of CuL nanocomplex and Mn$_3$O$_4$ in the presence of AS, Mn$_3$O$_4$/CuL bio-nanocolloid was obtained (Scheme 1).

Proton NMR spectrum of the free ligand has been recorded in DMSO at room temperature (Figure 2, top). The ligand exhibits hydroxyl proton (Ha) appearing at $\delta$ 15.203 ppm, the aromatic pyridine proton (Hb) appearing at $\delta$ 9.832 ppm, Hc appearing at $\delta$ 8.30 ppm, Hd appearing at $\delta$ 6.857 ppm, and aromatic and heteroaromatic proton signals appearing at $\delta$ 7.25–8.539 ppm. The chemical shift of hydroxyl proton is very high (15.203 ppm) indicating intramolecular hydrogen bond. $^{13}$C NMR spectrum (Figure 2, down) showed similar diagnostic features for the free ligand. Hydroxyl carbon (C-9) was found at 177.642 ppm, pyridine carbon (C-1) at 151.059 ppm and imine carbon (C-7) at 149.4526 ppm, and aromatic carbons were found at 108.474–149.426 ppm.

FT-IR spectra of L ligand, CuL nanocomplex and Mn$_3$O$_4$/CuL bio-nanocolloid are shown at Figure 3. In the free ligand (L), the band of 3365 cm$^{-1}$ was observed and assigned to $\nu$(O–H) absorption. The strong band at 1608 cm$^{-1}$ was related to stretching vibrations of C¼N functional group, which was confirmed by the presence of Schiff base. C¼C was assigned at 1545 cm$^{-1}$ [38]. Copper nanocomplex, $\nu$ C¼N (1608 cm$^{-1}$) was shifted to 1596 cm$^{-1}$ (lower frequencies), when complex was obtained [39]. The small bands at 495 and 522 cm$^{-1}$ are related to Cu–N and Cu–O bonds in nanocomplex. FT-IR spectrum of Mn$_3$O$_4$/CuL bio-nanocolloid exhibits one strong band at 507 cm$^{-1}$, which can be attributed to the vibrations of metal-oxygen confirming the presence of Mn$_3$O$_4$ NPs [40].

The presences of all elements in Mn$_3$O$_4$/CuL bio-nanocolloid were confirmed at EDAX of it and elemental analysis of this compound (Figure 4). Copper, manganese, carbon and oxygen were observed as elements in this nanocolloid. 34.49% of C, 52.45% of O, 12.86% of Mn and 0.19% of Cu were in this material. The morphology, size, and shape of this bio-material were investigated by TEM and SEM (Figure 3). Aggregation of particles was observed as TEM image. SEM image shows nanocube morphology of prepared nanocolloid, with width of 80 nm in diameter and 3 mm in length.

**Catalytic activities of Mn$_3$O$_4$/CuL bio-nanocolloid on the oxidation primary and secondary alcohols**

The catalytic activity of Mn$_3$O$_4$/CuL bio-nanocolloid was investigated on the oxidation of alcohols (Scheme 2).
The catalyst-free condition does not have the ability to oxidize the benzyl alcohol under different conditions. In this regard, catalytic experiments were initiated with the oxidation of benzyl alcohol (1 mmol) under air in the presence of H₂O₂ to have the standard conditions of the reaction. In this case, the nature of solvent and oxidant, temperature, reaction time and the quantity of catalyst were considered on the oxidation of benzyl alcohol as a blank reaction in this green system (Figure 5).

About 0.1 mmol concentration of alcohol and 80 °C are the best conditions for this oxidation reaction as the further evaluation demonstrated. The green oxidation of benzaldehyde was completed after 5 h (Figure 5(a–c)). Also, a survey of the results shown in Figure 5(e,d) revealed that a sufficient amount of catalyst loading of 0.007 g in the presence of 0.4 mmol oxidant led to higher conversion, but yield of product decreased with higher concentrations of catalyst. The effect of solvent on the catalytic performance is shown in Figure 5(f). The reaction did not proceed in aprotic and protic solvents such as ethanol (EtOH), methanol (MeOH), acetonitrile (CH₃CN), water and n-hexane. While, the solvent-free condition under air at 80 °C, benzyl alcohol was oxidized.

Scheme 2. The oxidation of primary and secondary alcohols catalysed by Mn₃O₄/CuL bio-nanocolloid using H₂O₂ to have O₂ and water as byproducts under ultrasonic irradiation.
converted to benzaldehyde completely. So, solventless was selected as a safe and green media for industrial applications. Based on the data in Figure 5(g), common oxidants such as O₂, TBAO (tetrabutyl ammonium oxone) and Oxone were weaker oxidants than H₂O₂ and TBHP for this transformation. However, H₂O₂ was selected as an ideal oxidant for further investigation. The ability synthesized Mn₃O₄, manganese salt, ligand (L) and CuL nanocomplex to promote the

Figure 5. (a–h) Optimization of oxidation of benzyl alcohol.
oxidation of benzyl alcohol which was then probed under the obtained optimized condition (Figure 5(h)). These compounds exhibited poor activity under this condition and the preferable catalytic performance of Mn$_3$O$_4$/CuL bio-nanocolloid was confirmed.

As described in documents [41], Lewis acid sites were believed as the active sites in catalytic oxidation of benzyl alcohol with H$_2$O$_2$ [42]. In this case, aqueous phase of H$_2$O$_2$ (30%) and benzyl alcohol from alcohol phase may interact with the catalyst on the interphase to generate the product benzaldehyde. This species attacks benzyl alcohol to form peroxycarboximidic acid intermediate (Figure 6), which is then converted into benzyl alcohol with concomitant regeneration of the catalyst. In view of the proposed mechanistic pathways for the catalytic oxidation of benzyl alcohol, it can be concluded that both the phenyl ring and OH group of benzyl alcohol may interact with the metal centre of Cu, whereas the inner active sites remain intact. However, the interaction of the phenyl ring and OH group with the outer metal ions of Cu is also possible via adsorption of the phenyl ring on Cu, as reported in reference [43].

Thereafter, we focussed on the consideration of the substrate scope under stirring. In this regards, a set of structurally and electronically primary and secondary alcohols were selected for this safe and cost-efficient strategy (Table 1). As shown in Table 1, good to excellent yields were obtained for different primary and secondary benzyl alcohols, except for those with the aryl ring substituted with a nitro group. It should be noted that the corresponding carboxylic acids and ester were not observed in this green system and over-oxidation did not happen.

Finally, we compared the conditions of oxidation of benzyl alcohol in this clean and cheap system with the results of other reports using hydrogen peroxide in different conditions (Table 2). The results showed that this Mn$_3$O$_4$/CuL bio-nanocolloid bionanocomposite could be used as a robust, reusable and active heterogeneous catalyst in the oxidation of primary and secondary alcohols with H$_2$O$_2$.

**Reusability of catalyst**

Recovery and the catalytic activity are imperative options for the industrial application of this biocatalyst. For this aim, the structure of catalyst must be unchanged. A comparison of the FT-IR spectra of the used Mn$_3$O$_4$/CuL bio nanocolloid (six recovery cycles) with those of the fresh catalyst showed that the structure of the catalyst remained almost completely intact (Figure 7(a)). On the other hand, the reusability of the Mn$_3$O$_4$/CuL bio nanocolloid was explored in the oxidation of benzyl alcohol. When the reactions were completed, the nanocolloid was separated by centrifugation after addition of the ethyl acetate. Recovered catalyst in dry state was used for the next runs. Stability as well as the activity of it was investigated and Mn$_3$O$_4$/CuL bionanocolloid was recycled for six times. Remarkable results (100–90%) of benzaldehyde.

were gained showing excellent catalytic activity of nanocolloid without noticeable loss (Figure 7(b)).

The features of our clean strategy on recycling of catalyst are the easy work up and convenient separation of product using green solvent (ethyl acetate or ethanol) from reactions. This method is not only eco-friendly but also less time consuming, cost effective, stable operation, efficient and safer. On the other hand, natural starting material for catalyst preparation, a long-term stability of catalyst, using ideal oxidant, and solventless show the great potential in scalability for actual industries applications. These features as concepts in economical and sustainable modern oxidation systems along with good reusability of the bio-catalyst render a practical strategy to address the environmental and industrial applications.

Conclusions

In summary, the first bio-nanocomposite based on weeds was synthesized. We prepared a novel of bionanocolloid successfully, by incorporating copper nanocomplex as a biocompatible molecule with Mn₃O₄ nanoparticles under ultrasonic agitation in the presence of Amaranthus spinosus. As a heterogeneous catalyst, the Mn₃O₄/CuL nanocatalyst efficiently oxidized a wide range of primary and secondary alcohols to the corresponding carbonyl compounds using H₂O₂ and under solvent free conditions as ideal oxidant and reaction media, respectively. Using cheap and natural starting materials, reusability, and recyclability of the catalyst are salient features of this green strategy from an economic and environmental point of view.
