How the Instability of Ranks Under Long Memory Affects Large-Sample Inference

Shuyang Bai and Murad S. Taqqu

Abstract. Under long memory, the limit theorems for normalized sums of random variables typically involve a positive integer called “Hermite rank.” There is a different limit for each Hermite rank. From a statistical point of view, however, we argue that a rank other than one is unstable, whereas, a rank equal to one is stable. We provide empirical evidence supporting this argument. This has important consequences. Assuming a higher-order rank when it is not really there usually results in underestimating the order of the fluctuations of the statistic of interest. We illustrate this through various examples involving the sample variance, the empirical processes and the Whittle estimator.

Key words and phrases: Long-range dependence, Long memory, Hermite rank, power rank, non-Gaussian limit, instability, large-sample inference.

1. INTRODUCTION

Suppose that \(D\) is a data set, and one has a statistical model for \(D\) which involves a random stationary sequence \(\{X(n)\}\), referred to as noise. Let \(T = T(D)\) be a sample statistic of interest. Deriving the asymptotic distribution for the statistic \(T\) as the sample size tends to infinity is a standard practice in large sample inference. The asymptotic distribution is useful for reporting confidence intervals, conducting hypothesis tests, etc.

When the construction of the statistic \(T\) involves summing the data and if the stationary noise \(\{X(n)\}\) is weakly dependent, then the asymptotic distribution for the statistic \(T\) as the sample size tends to infinity is a standard practice in large sample inference. The asymptotic distribution is useful for reporting confidence intervals, conducting hypothesis tests, etc.

1 The term “Hurst index” is also frequently used for the self-similarity parameter of self-similar processes arising from the normalized limit of the sum of \(X(n)\) (see Pipiras and Taqqu [64]). It is also common to introduce the so-called memory parameter \(d\) in the context of (2), re-expressed as Cov\([X(n), X(0)]\) \(\approx n^{2H-2}\) as \(n \to \infty\), where \(-1 < 2H - 2 < 0\). In fact, (2) is also a common characterization of long memory. We refer the reader to the recent monographs Beran et al. [9], Giraitis, Koul and Surgailis [36], Samorodnitsky [69] and Pipiras and Taqqu [64] for comprehensive introductions to the notion long memory.

In view of (1), when deriving the asymptotic distribution of the sum, one needs to associate the following behavior of the variance of partial sums:

\[
\text{Var}\left[\sum_{n=1}^{N} X(n)\right] \approx N^{2H} \quad \text{as } N \to \infty,
\]

where \(\approx\) means asymptotic equivalence up to some positive constant, the parameter \(H \in (1/2, 1)\) is called the Hurst index.\(^1\) Normally when the dependence is weak, one expects \(H = 1/2\) in (1), that is, the growth of the variance is linear. The superlinear growth in (1) is typically due to the slow decay of the covariance of \(\{X(n)\}\):

\[
\text{Cov}[X(n), X(0)] \approx n^{2H-2} \quad \text{as } n \to \infty,
\]

where \(-1 < 2H - 2 < 0\). In fact, (2) is also a common characterization of long memory. We refer the reader to the recent monographs Beran et al. [9], Giraitis, Koul and Surgailis [36], Samorodnitsky [69] and Pipiras and Taqqu [64] for comprehensive introductions to the notion long memory.

Shuyang Bai is Assistant Professor, Department of Statistics, University of Georgia, Athens, GA 30602, US (e-mail: bsys9142@uga.edu). Murad S. Taqqu is Professor, Department of Mathematics and Statistics, Boston University, Boston, MA 02215, US (e-mail: murad@bu.edu).
normalization $N^{-H}$ to $\sum_{n=1}^{N} X(n)$ rather than the standard $N^{-1/2}$ normalization. These limit theorems have been applied in many statistical studies. See Section 3 below.

This paper makes the following basic argument: while these limit theorems are definitely of probabilistic interest, their immediate application to statistical inference can lead to problems. This is because these limit theorems can be unstable, that is, they can often cease to hold when $\{X(n)\}$ is slightly perturbed. In particular, the limit theorems under long memory often depend critically on an integer quantity called rank, for example, the Hermite rank in the Gaussian context. We will show that the rank is unstable when it takes value greater than one, and it easily collapses to rank one when there is a slight perturbation.

The notion of rank, however, is not relevant when the data is weakly dependent. We indicate that under weak dependence, limit theorems are robust against, for example, a transformation of the data. We illustrate this by considering various types of weak dependence, such as strong mixing, Gaussian subordination and Bernoulli shifts.

The paper is organized as follows. The rank instability issue is discussed in Section 2. In Section 3, we provide some examples on how the instability of rank can affect statistical results. In Section 4, we carry out an empirical study which supports the instability argument. In contrast, we show in Section 5 that the central limit theorems under weak dependence are not subject to such instability issues. Section 6 contains conclusions and suggestions. Some technical extensions are found in the Appendix.

2. THE INSTABILITY OF RANKS UNDER LONG MEMORY

In this section, we introduce the notion Hermite rank and point out its instability. We focus on the simple scenario of instantaneous transformation of a Gaussian stationary process. (The noninstantaneous case is somewhat technical and is deferred to the Appendix.) We then address the case where the model involves a non-Gaussian linear (moving-average) process, where the corresponding notion of Hermite rank is called the Appell rank or the power rank.

Throughout the paper, the notation $a(n) \approx b(n)$ means $\lim_{n \to \infty} a(n)/b(n) = c$ for some generic constant $0 < c < \infty$ that can change from expression to expression. We note that in many places, one can include a slowly varying function in the asymptotic relation, for example, a logarithmic function (see, e.g., Bingham, Goldie and Teugels [14]), but for simplicity we do not do that.

2.1 Transformation of Gaussian Processes

We want to consider possibly nonlinear finite-variance transformations of Gaussian random variables. To do so, let $Z$ be a standard normal random variable, $\gamma(dx)$ be the standard Gaussian measure $(2\pi)^{-1/2} e^{-x^2/2} dx$ on $\mathbb{R}$, and let

$$L^2(\gamma) = \{ G(\cdot) : \mathbb{E}G(Z)^2 < \infty \}.$$

It is well known (see, e.g., Pipiras and Taqqu [64], Proposition 5.1.3) that $\{ \sqrt{m!} H_m(\cdot), m \geq 0 \}$ forms an orthonormal basis of $L^2(\gamma)$, where $\{ H_m(\cdot), m \geq 0 \}$ are Hermite polynomials defined as $H_0(x) = 1$ and

$$H_m(x) = (-1)^m e^{x^2/2} \frac{d}{dx} H_{m-1}(x) e^{-x^2/2} \quad \text{for } m \geq 1.$$

Thus, $H_1(x) = x$, $H_2(x) = x^2 - 1$ and $H_3(x) = x^3 - 3x$, etc. We can now define the Hermite rank of a function $G \in L^2(\gamma)$.

**Definition 2.1.** Suppose that $G(\cdot) \in L^2(\gamma)$. Let $Z$ be a standard Gaussian random variable. The **Hermite rank** $k$ of $G(\cdot)$ is defined as

$$k = \inf \left\{ m \geq 1 : \mathbb{E}G(Z) H_m(Z) \right\}$$

for some sequence $c_m$ satisfying $c_k \neq 0$, where the series converges in the $L^2(\gamma)$-sense. By the orthonormality of $\{ \sqrt{m!} H_m(\cdot) \}$, we have

$$c_m = \frac{\mathbb{E}[G(Z) H_m(Z)]}{m!} \quad \text{for } m \geq 0.$$

Note that $c_0 = \mathbb{E}G(Z)$ since $H_0(Z) = 1$. Furthermore, since the Hermite polynomials $\{ H_m(\cdot), 0 \leq m \leq k \}$ form a basis for polynomials of degree less than equal to $k$, the definition (4) can be re-expressed as

$$k = \inf \left\{ m \geq 1 : \mathbb{E}[ (G(Z) - \mathbb{E}G(Z)) Z^m ] \neq 0 \right\}.$$
REMARK 2.3. The Hermite rank of $G(x)$ is the same as that of $G(x) + a$, for any $a \in \mathbb{R}$, since relation (5) involves centering.

Now suppose that $\{X(n)\}$ is a long-memory stationary Gaussian process satisfying (2). We may assume without loss of generality that it is standardized, that is, $EX(n) = 0$ and $\text{Var}[X(n)] = 1$. The following lemma explains the role that the Hermite rank plays in determining the asymptotic behavior of the covariance of the transformed sequence $\{G(X(n))\}$ (see page 223 of Beran et al. [9]).

**LEMMA 2.4.** If $G(\cdot)$ has Hermite rank $k$, then
\[
\text{Cov}[G(X(n)), G(X(0))] 
\approx \text{Cov}[X(n), X(0)]^k 
\approx n(2H-2)^k.
\]

**REMARK 2.5.** Comparing (8) and (2), we note that for functions $G(\cdot)$ that have Hermite rank $k = 1$, the Hurst index of $\{G(X(n))\}$ is the same as the Hurst index of $\{X(n)\}$. In general, since $2H - 2 < 0$, the higher the Hermite rank $k$ is, the faster the covariance decays as $n \to \infty$. Note that in view of (2) and (8), for $\{G(X(n))\}$ to have long memory, one needs
\[
(2H - 2)k > -1 \iff H > 1 - \frac{1}{2k}.
\]
This is natural because when $k > 1$, the covariance of $\{G(X(n))\}$ decays faster than that of $\{X(n)\}$ and thus $H$ must be greater than $1 - 1/(2k)$ in order to ensure that $\{G(X_n)\}$ has long memory.

### 2.2 Asymptotic Behavior

Now returning to the theme of the introduction: suppose that in order to derive the asymptotic distribution of the statistics $T$ of interest, one first needs to obtain the distributional limit as $N \to \infty$ of
\[
\frac{1}{A(N)} \sum_{n=1}^{[N]} (G(X(n)) - \mathbb{E}G(X(n))), \quad t \in [0, 1],
\]
where $G(\cdot) \in L^2(\gamma)$, $A(N)$ is a suitable normalization, and $[\cdot]$ stands for the integer part.

**THEOREM 2.6** (Dobrushin and Major [31], Taqqu [76], Breuer and Major [15], Major [57]). Suppose that $G$ has Hermite rank $k$. Then the following conclusions hold.

- **Central limit case**: suppose that $H < 1 - \frac{1}{2k}$.

Then $\{G(X(n))\}$ has short memory in the sense that
\[
\sigma^2 := \sum_{n=-\infty}^{\infty} \text{Cov}[G(X(n)), G(X(0))]
\]
converges absolutely and
\[
\frac{1}{N^{1/2}} \sum_{n=1}^{[N]} (G(X(n)) - \mathbb{E}G(X(n))) \quad \overset{f.d.d.}{\longrightarrow} \quad \sigma B(t), \quad t \geq 0,
\]
where $\overset{f.d.d.}{\longrightarrow}$ denotes convergence of the finite-dimensional distributions and $B(t)$ is the standard Brownian motion.

- **Noncentral limit case**: suppose that $H > 1 - \frac{1}{2k}$.

Then $\{G(X(n))\}$ has long memory with Hurst index:
\[
H_G = (H - 1)k + 1 \in \left(\frac{1}{2}, 1\right).
\]
Furthermore, as $N \to \infty$, we have\(^2\)
\[
\frac{1}{N^{H_G}} \sum_{n=1}^{[N]} (G(X(n)) - \mathbb{E}G(X(n))) \quad \overset{f.d.d.}{\longrightarrow} \quad c Z_{H_G,k}(t),
\]
for some $c \neq 0$, and
\[
Z_{H_G,k}(t) = \int_{\mathbb{R}^k} \left[ \prod_{j=1}^{k} \int_0^t ds \right] B(dx_1) \cdots B(dx_k),
\]
is the so-called $k$th order Hermite process, where $\int_{\mathbb{R}^k} \prod_i B(dx_{i1}) \cdots B(dx_{ik})$ denotes the $k$-tuple Wiener–Itô integral with respect to the standard Brownian motion $B(\cdot)$. The prime $'$ indicates that one does not integrate on the diagonals $x_i = x_j$.

\(^2\)In fact, we have weak convergence in the space $D[0,1]$ with uniform metric.
REMARK 2.7. When the Hermite rank \( k = 1 \), one has
\[
H_G = H
\]
and the limit \( Z_{HG,k}(t) \) in Theorem 2.6 is the fractional Brownian motion \( B_H(t) \), namely, the centered Gaussian process determined by the following covariance structure:
\[
\text{Cov}[B_H(s), B_H(t)] = \frac{1}{2}(|s|^2H + |t|^2H - |s - t|^2H).
\]
The preceding covariance is shared by all the other Hermite processes. When the Hermite rank \( k = 2 \), \( Z_{HG,2}(t) \) is called the Rosenblatt process (see Rosenblatt [68] and Taqqu [75]). The Hermite process \( Z_{HG,k}(t) \) in (13) admits different representations. See Pipiras and Taqqu [63].

REMARK 2.8. The boundary case \( H = 1 - \frac{1}{2k} \) typically falls in the central limit theorem regime (convergence to Brownian motion) after modifying the normalization \( N^{-1/2} \) to include some slowly varying functions (Theorem 1’ of Breuer and Major [15]). In general, the convergence of finite-dimensional distributions \( \overset{f.d.d.}{\rightarrow} \) in the short-memory case cannot be strengthened to weak convergence \( \Rightarrow \) in \( D[0,1] \) unless some additional assumption is imposed on \( G \), for example, \( G \) being a polynomial (Chambers and Slud [17]).

The long-memory Gaussian \( \{X(n)\} \) may be directly used as a model for the long-memory stationary noise. For statistical theory, however, it is often desirable to allow departure from Gaussianity, for example, to accommodate the situations where the noise distribution is skewed or heavy-tailed. Within the same framework, a way to achieve such flexibility is as follows. Suppose that there is an underlying long-memory Gaussian stationary process \( \{Y(n)\} \). Assume without loss of generality that \( \{Y(n)\} \) is standardized. Now suppose that the noise sequence \( \{X(n)\} \) in the model is given by
\[
X(n) = F(Y(n)).
\]

REMARK 2.9. There are different perspectives to interpret (14). First, note that when \( F(\cdot) \) is nonlinear, \( X(n) \) is non-Gaussian. So \( F(\cdot) \) can represent the departure from the ideal Gaussian assumption. Hence, when the noise \( X(n) \) is modeled by (14) with an unknown \( F(\cdot) \), this provides great model flexibility. Note that a proper choice of \( F(\cdot) \) can match any marginal distribution for \( X(n) \). Second, from the perspective of analysis of robustness, one may view \( X(n) \) as a perturbed version of \( Y(n) \), where \( X(n) \) is close to \( Y(n) \), that is, \( F(\cdot) \) is close to the identity function.

Following the same statistical inference procedure that leads to (9), we then focus on the distributional limit of
\[
\frac{1}{A(N)} \sum_{n=1}^{[Nt]} (G \circ F(Y(n)) - \mathbb{E}G \circ F(Y(n)))
\]
as \( N \to \infty \).

REMARK 2.10. We emphasize the different roles played by \( F(\cdot) \) and \( G(\cdot) \). The function \( F(\cdot) \) accounts for an unknown and uncontrollable departure from the Gaussian \( Y(n) \). On the other hand, the function \( G(\cdot) \) depends on the statistical procedure of interest and is therefore typically precisely known. For example, \( G \) is typically the identity transformation for inference of the mean \( \mathbb{E}X(n) = \mathbb{E}F(Y(n)) \).

2.3 Basic Claim

We are now ready to make the following claim which will be justified below. The case of noninstantaneous (multivariate) \( F \) (and also \( G \)) will be addressed in the Appendix (the issues remain essentially the same).

CLAIM 2.11. It is typically the case that:

(a) the function \( G \circ F \) has Hermite rank 1;
(b) the process \( \{X(n)\} \) has long memory with the same Hurst index \( H \) as \( \{Y(n)\} \) in (14).

JUSTIFICATION OF THE CLAIM. Let \( Z \) be standard Gaussian. Since \( H_1(Z) = Z \), requiring the function \( G \circ F \) to have Hermite rank \( k \geq 2 \) is equivalent to
\[
\mathbb{E}[(G \circ F)(Z)Z] = 0.
\]
This requirement is very restrictive, and is, moreover, unrelated to the usual size or smoothness conditions typically imposed on the perturbation \( F \). Unlike the precisely known \( G(\cdot) \) which is related to the method of inference considered, one has no control nor accurate knowledge of the function \( F(\cdot) \). There is thus no a priori reason that \( F(\cdot) \) be such that (15) holds. But if (15) does not hold, then the Hermite rank of \( G \circ F \) is 1, which justifies part (a) of the Claim 2.11.

Applying the same reasoning, the perturbation function \( F(\cdot) \) is also very likely to be such that
\[
\mathbb{E}[F(Z)Z] \neq 0
\]
and hence to have Hermite rank 1. Then in view of Lemma 2.4 and Remark 2.5, this justifies part (b) of the Claim 2.11. □
Remark 2.12. The Claim 2.11 indicates not only the instability of a Hermite rank higher than 1, but also the stability of the Hermite rank 1 and hence the Hurst index of the noise model. Then, as suggested by the Claim 2.11, if \( G \circ F \) has Hermite rank 1, by Theorem 2.6 and Remark 2.7, one has
\[
\frac{1}{N^H} \sum_{n=1}^{[N]} (G \circ F(Y(n)) - \mathbb{E} G \circ F(Y(n))) \approx c Z_{H,1}(t) = c B_H(t)
\]
for some \( c > 0 \), where \( B_H(t) \) is the fractional Brownian motion with Hurst index \( H \). The theorem thus also implies the stability of fractional Brownian motion as the limit.

Remark 2.13. In statistics, one sometimes needs limit theorems for functionals other than the sum. A typical example is the quadratic form \( \sum_{m,n=1}^N a(n - m)X(n)X(m) \). Limit theorems in this case depend on not only the “memory” of \( \{X(n)\} \) but also the “memory” of the coefficient \( a(n) \) (see, e.g., Avram and Terrin [79]).

2.4 The Level Shift Case

One may consider making Claim 2.11 a genuine mathematical statement by, for example, considering \( F(\cdot) \) as a random element in a suitable function space with a “prior probability model,” as long as that model assigns a small probability to the set of \( F(\cdot) \) on which (15) happens.

In the following theorem, we consider the simple case where the perturbation is given by a level shift of size \( z \), namely, if \( F(y) = z + y \) so that \( G \circ F(\cdot) = G(\cdot + z) \). To understand the assumptions, note that we want to exclude the case where \( G(\cdot) \) is constant, since then \( G(\cdot + z) \) remains equal to \( G(\cdot) \). We also want \( G(\cdot + z) \) to be in \( L^2(y) \).

Theorem 2.14. Suppose that the function \( G(\cdot) \in L^2(y) \) has an arbitrary Hermite rank, \( G(\cdot) \) is not constant a.e., and assume that there exists \( \delta > 0 \), so that \( G(\cdot + z) \in L^2(y) \) for all \( |z| < \delta \). Then there exists \( \varepsilon \in (0, \delta) \), such that the Hermite rank of \( G(\cdot + z) \) is 1 for all \( z \in (-\varepsilon, 0) \cup (0, +\varepsilon) \).

The proof can be found in Bai and Taqqu [6]. In that paper, we also study what happens when the shift tends to zero as the sample size tends to infinity, which is analogous to the near integration analysis of unit roots (see Phillips [62]). In Bai and Taqqu [6], we also consider transformations other than the shift, for example, the scaling \( F(z) = z \) so that \( G \circ F(y) = G(z) \).

2.5 Transformation of Linear Processes

Another popular class of models for a stationary, not necessarily Gaussian, noise \( \{Y(n)\} \) is the so-called (causal) linear process:
\[
Y(n) = \sum_{i=0}^{\infty} a_{n-i} \varepsilon_i,
\]
where \( \varepsilon_i \)’s are assumed to be i.i.d. random variables (not necessarily Gaussian) with mean 0 and variance 1 and \( \sum_n a_n^2 < \infty \). When
\[
a_n \approx n^{H-3/2}, \quad 1/2 < H < 1 \quad \text{as} \quad n \to \infty,
\]
ones has Cov\([Y(n), Y(0)] \approx n^{2H-2}; and thus \( Y(n) \) has long memory with Hurst index \( H \). The well-known fractionally-integrated noise model (see, e.g., Granger and Joyeux [40]) satisfies (18). We shall assume (18) throughout this section.

Theorem 2.6 can be extended to linear processes. In this case, the larger class of polynomials called Appell polynomials (Avram and Taqqu [3]) plays an analogous role to that of the Hermite polynomial in Section 2.1. One can define the so-called Appell rank of a function \( G(\cdot) \) as in (5), with Hermite polynomials replaced by the Appell polynomials, given that the expansion is valid (e.g., when \( G(\cdot) \) is a finite-order polynomial). However, in this framework (Surgailis [73]), the class of functions \( G(\cdot) \)’s that can be treated is rather restrictive.

Given a function \( G(\cdot) \) and a random variable \( Y \) satisfying \( \mathbb{E} G(Y)^2 < \infty \), let
\[
G_\infty(y) = \mathbb{E} G(Y + y)
\]
given that the expectation exists and suppose that \( G_{\infty}(\cdot) \) has derivatives of order sufficiently high. The power rank of \( G(\cdot) \) with respect to \( Y \) is defined as
\[
\inf\{m \geq 1 : G_{\infty}^{(m)}(0) \neq 0\},
\]
where \( G_{\infty}^{(m)}(y) \) denotes the \( m \)th derivative of \( G_{\infty}(y) \). In fact, the power rank in (20) coincides with the Hermite rank (4) if \( Y \) is Gaussian. This was stated in Ho and Hsing [45], and see Bai and Taqqu [6] for a proof.
The case where $G$ is a polynomial was treated in Lévy-Leduc and Taqqu [56].

Now we can state the following limit theorems (for simplicity we omit the inclusion of some technical conditions, see Ho and Hsing [45] and Pipiras and Taqqu [64]):

**Theorem 2.15** (Ho and Hsing [45]). Suppose that $\mathbb{E}G(Y(0)) < \infty$ and $G(\cdot)$ has power rank $k \geq 1$ with respect to $Y(0)$ in the sense of (20). Under some additional technical conditions, statements exactly analogous to Theorem 2.6 hold with the role of the Hermite rank replaced by the power rank.

**Remark 2.16.** Using similar arguments as Section 2.1, one sees that a power rank higher than 1 is also unstable to perturbation: to get a power rank higher than 1, one needs the restrictive condition

$$G^{(1)}(0) = \frac{d}{dy}\mathbb{E}(Y + y)|_{y=0} = 0,$$

which can be easily perturbed by compositing $G$ with a transformation before. So an analog of Claim 2.11 may be stated in this context.

Below we provide some further remarks on the instability phenomenon.

**Remark 2.17.** We mention that Surgailis [74] established some results which can be interpreted as the “robustness” of Theorem 2.15 against additive noise. Roughly speaking, Surgailis [74] showed that if the long-memory linear process $Y(n)$ is replaced by $Y'(n) = Y(n) + U(n)$ with $U(n)$ specified as some short-memory models, then the noncentral convergence in Theorem 2.15 still holds, where the power (or Appell) rank is now with respect to the distribution of $Y'(n)$. Nevertheless, the instability discussed earlier still applies. First, the rank can still be unstable under a transformation. Second, even without considering a transformation perturbation, one has typically no accurate knowledge of the marginal distribution of $Y'(n)$. A change in the distribution will affect the rank defined through (20).

**Remark 2.18.** It is important to consider not only the limit distribution that one obtains, but also the normalization since the latter corresponds to the magnitude of the fluctuations of the partial sum. When the true rank (Hermite or power) is indeed 1, but one assumes a higher-order Hermite rank from some statistical consideration, this will lead to underestimation of the magnitude of the fluctuations of the partial sum since $H_G < H$ in Theorem 2.6.

### 3. Examples in Statistics

In this section, we review statistical problems in the literature related to limit theorems involving different ranks. We shall elaborate on some examples: sample variance, empirical processes, Whittle likelihood, and nonparametric estimation, to demonstrate how the asymptotic statistical theories are affected by the instability discussed in Section 2.

#### 3.1 Sample Variance

In the context of long memory, with the complexity introduced by the limit theorems, scale estimation becomes a problem. We only discuss the case where the data $\{X(n)\}$ is a Gaussian process, but everything can be extended to a linear process $\{X(n)\}$ (see Section 2.5).

Assume then that $\{X(n)\}$ is a long-memory stationary Gaussian process with Hurst index $H \in (1/2, 1)$, unknown mean $\mu$ and unknown variance $\sigma^2$. Consider the estimation of $\sigma^2$ using the sample variance

$$\hat{\sigma}_N^2 := \frac{1}{N} \sum_{n=1}^{N} (X(n) - \bar{X}_N)^2,$$

where $\bar{X}_N = (X(1) + \cdots + X(N))/N$ is the sample mean. In the short-memory situation, say if $X(n)$ were i.i.d., it is well known that $\hat{\sigma}_N^2$ is asymptotically normal. The situation is, however, delicate. Indeed, express (21) as

$$\hat{\sigma}_N^2 = \frac{1}{N} \sum_{n=1}^{N} (X(n) - \mu)^2 + (\bar{X}_N - \mu)^2$$

$$= U_N + V_N.$$

We can write

$$U_N - \sigma^2$$

$$= \frac{1}{N} \sum_{n=1}^{N} (X(n) - \mu)^2 - \sigma^2$$

and

$$V_N = (\bar{X}_N - \mu)^2$$

$$= N^{-1/2} \left[ \frac{1}{\sqrt{N}} \sum_{n=1}^{N} ((X(n) - \mu)^2 - \sigma^2) \right].$$

Note that the term $X(n) - \mu$ has Hermite rank $k = 1$, and the term $(X(n) - \mu)^2$ has expectation $\sigma^2$ and Hermite rank $k = 2$, since $\mathbb{E}(X(n) - \mu)^2 X(n) = 0$. 
Thus when $H < 3/4$, in view of Theorem 2.6, the term in the brackets in the right-hand sides (23) and (24) converge as $N \to \infty$. Since $H < 3/4$ implies $N^{2H-2} \ll N^{-1/2}$, the term $V_N$ is asymptotically negligible, compared to $U_N - \sigma^2$, and hence $N^{1/2}(\hat{\sigma}_N^2 - \sigma^2)$ has the same limit as $N^{1/2}U_N$ as $N \to \infty$. Thus,

$$N^{1/2}(\hat{\sigma}_N^2 - \sigma^2) \overset{d}{\to} N(0,s_1^2)$$

for some $s_1 > 0$.

When $H > 3/4$, in view of Theorem 2.6 with $k = 2$, we write

$$U_N - \sigma^2 = N^{2H-2} \left[ \frac{1}{N^{2H-1}} \sum_{n=1}^N (X(n) - \mu)^2 - \sigma^2 \right],$$

and $V_N$ is as in (24). Now both $U_N$ and $V_N$ contribute to the limit, where we have by a multivariate version of Theorem 2.6 (see, e.g., Bai and Taqqu [4])

$$N^{2-2H}(\hat{\sigma}_N^2 - \sigma^2) \overset{d}{\to} a_H Z_{2H-1,2}(1) + b_H Z_{H,1}(1)^2,$$

where $Z_{2H-1,k}(t), k = 1, 2$ are the Hermite processes in (13) defined by the same Brownian integrator $B(\cdot)$. for some constants $a_H, b_H > 0$. See also Dehling and Taqqu [29].

We now suppose that $\{X(n)\}$ is perturbed by a transformation in the spirit of Claim 2.11, which leads to consider the case where both $X(n)$ and $[X(n) - \mu]^2$ have Hermite rank 1. Then writing

$$U_N - \sigma^2 = N^{H-1} \left[ \frac{1}{N^H} \sum_{n=1}^N ((X(n) - \mu)^2 - \sigma^2) \right]$$

and

$$V_N = N^{2H-2} \left[ \frac{1}{N^H} \sum_{n=1}^N (X(n) - \mu)^2 \right],$$

we can apply Theorem 2.6 with $k = 1$. Since $H < 1$, we have $N^{2H-2} \ll N^{H-1}$, and thus only the term $U_N$ contributes to the limit. Then $N^{1-H}(\hat{\sigma}_N^2 - \sigma^2)$ has the same limit as

$$N^{1-H}(U_N - \sigma^2) = \frac{1}{N^H} \sum_{n=1}^N ((X(n) - \mu)^2 - \sigma^2],$$

namely, $c_H Z_{H,1}(1)$ for some $c_H > 0$, where $Z_{H,1}$ is the fractional Brownian motion. Hence,

$$N^{1-H}(\hat{\sigma}_N^2 - \sigma^2) \overset{d}{\to} c_H Z_{H,1}(1),$$

which is different from (25).

**Remark 3.1.** Under the above perturbation consideration, there is no dichotomy between $H < 3/4$ and $H > 3/4$ in (26), and the normalization is always $N^{1-H}$, which is of smaller order than both $N^{1/2}$ and $N^{2H-2}$. In the case $H < 3/4$, however, we get a Gaussian limit with or without perturbation. Hence without the perturbation consideration, there is the danger of underestimating the fluctuation magnitude of the sample variance, namely, taking the fluctuation to be of the order $N^{-1/2}$ when $H < 3/4$ and $N^{2H-2}$ when $H > 3/4$, whereas they are of the order $N^{H-1}$. We also mention that similar considerations also apply to the study of the asymptotic behavior of sample autocovariance/correlation (see, e.g., Hosking [48], Wu, Huang and Zheng [83] and Lévy-Leduc, Boistard and Moulines [54]).

### 3.2 Empirical Processes

Empirical processes play important roles in many statistical problems. We refer the reader to Dehling, Mikosch and Sorensen [25] for an introduction to empirical processes of dependent data. Let $\{X(n)\}$ be a stationary process with marginal cdf $F(x)$. The corresponding centered empirical process is defined as

$$F_N(x) = \frac{1}{N} \sum_{n=1}^N I\{X(n) \le x\} - F(x).$$

When $\{X(n)\}$ is i.i.d., it is well known that $N^{1/2}F_N(x)$ converges weakly in $D(-\infty, \infty)$ to $B_0(F(x)) = B(F(x)) - F(x)B(1)$, where $B_0(t) = B(t) - tB(1)$ is a Brownian bridge and $B(t)$ is a Brownian motion. Under some weak dependence conditions on $\{X(n)\}$, the process $N^{1/2}F_N(x)$ converges weakly in $D(-\infty, \infty)$ to a centered Gaussian process $G(x)$ with covariance structure given by

$$\mathbb{E}G(x)G(y) = \sum_{n=\infty}^{\infty} \text{Cov}[I(X(0) \le x), I(X(n) \le y)];$$

see, for example, Theorem 4.1 of Dehling and Philipp [26].

When $X(n)$ has long memory, the corresponding weak convergence results become rather different in nature. Indeed, assume that $X(n) = G(Y(n))$ where $\{Y(n)\}$ is a standardized stationary Gaussian process with Hurst index $1/2 < H < 1$. We define the deterministic function

$$J_m(x) = \frac{1}{m!} \mathbb{E}I\{G(Y(0)) \le x\}H_m(Y(0)).$$
where $H_m(\cdot)$ is the $m$th order Hermite polynomial. Note that for any fixed $x \in \mathbb{R}$, $J_m(x)$’s are the coefficients of the Hermite expansion (5) of the function $\Delta_1(y) = I\{G(y) \leq x\} - F(x)$. We have the following result.

**Theorem 3.2** (Theorem 1.1 of Dehling and Taqqu [28]). Let

$$k = \inf\{m \geq 1 : J_m(x) \neq 0\}$$

for at least one $x \in \mathbb{R}$,

and assume that $H > 1 - \frac{1}{2k}$. Then we have the following weak convergence in $D(-\infty, +\infty)

$$N^{1-H}F_N(\cdot) \Rightarrow c J_1(\cdot),$$

where $Z_{H_0, k}(\cdot)$ is the Hermite process as in (13), and $H_k = (H - 1)k + 1$ as in (11).

**Remark 3.3.** It is interesting to note that in the long-memory case, the limit process

$$\{J_m(x)Z_{H_0, k}(1), x \in \mathbb{R}\}$$

is quite degenerate, namely, it has correlation 1 between any different points $x_1, x_2 \in \mathbb{R}$, in contrast to the weak dependence case where the limit Gaussian process $G(x)$ admits a rich correlation structure [see (28)].

By the perturbation argument, one may assume that the rank $k = 1$, regardless of the choice of $G(\cdot)$ in a statistical application of Theorem 3.2. In fact, the definition of rank (29) makes the assumption even more appealing in this context, because $J_1(x) \neq 0$ for just one point $x$ would make $k = 1$. From this point of view, the only practically relevant convergence in (30) is

$$N^{1-H}F_N(\cdot) \Rightarrow c Z J_1(\cdot),$$

where $Z$ is a standard Gaussian variable, and thus the fluctuation of the empirical process is practically always of the order $N^{H-1}$. The convergence (30) can be applied to study the asymptotic behavior of U-statistics and V-statistics (see Corollary 1 of Dehling and Taqqu [28]). It is also applied to develop the asymptotic theories of estimation of the probability density function $f = F'$ (see Csörgő and Mielniczuk [23] and Section 3.5).

### 3.3 Whittle Likelihood

In the parametric estimation for time series, the so-called Whittle pseudo-likelihood is a computationally efficient approximation to the Gaussian likelihood, which bypasses the inversion of a covariance matrix in the latter. The resulting Whittle estimator and its semiparametric extensions are found particularly useful in the long-memory context for the estimation of the Hurst parameter $H$. For more details on the background and motivation, we refer to Section 5.5 of Beran et al. [9] or Chapter 10 of Pipiras and Taqqu [64]. We shall focus on the rank instability issue in the asymptotic theory developed in Giraitis and Taqqu [39]. The asymptotic theory in this context depends on the limit theorem for quadratic forms, which is more delicate than the limit theorems for sums. The instability issue in this context exhibits some distinct features compared with the previous cases.

Suppose a stationary time series $\{X(n)\}$ has spectral density (see, e.g., Chapter 1 of Pipiras and Taqqu [64])

$$f(\lambda; \theta, \sigma) = \sigma^2 g_\theta(\lambda) > 0, \lambda \in (-\pi, \pi)$$

so that

$$\text{Cov}[X(n), X(0)] = \int_{-\pi}^{\pi} e^{inx} f_\theta(\lambda; \theta, \sigma) d\lambda,$$

where $\sigma$ and $\theta = (\theta_1, \ldots, \theta_p)$ are unknown parameters. Assume that the normalization condition (scale identifiability) holds:

$$\int_{-\pi}^{\pi} \log g_\theta(\lambda) d\lambda = 0,$$

under which $\sigma^2$ becomes the mean squared error of the one-step prediction by the Kolmogorov’s formula (see, e.g., Section 5.8 of Brockwell and Davis [16]). Suppose that we want to estimate the unknown parameter $\theta$. Under long memory, the choice of $\theta$ typically includes $H$. Define

$$a_\theta(n) = \int_{-\pi}^{\pi} e^{in\lambda} \frac{1}{g_\theta(\lambda)} d\lambda$$

and

$$w_\theta(m, n) = \int_{-\pi}^{\pi} g_\theta(\lambda) \frac{\partial^2}{\partial \theta_m \partial \theta_n} \left[g_\theta(\lambda)\right]^{-1} d\lambda.$$

The so-called Whittle estimator $\hat{\theta}_N$ of $\theta$ is given by

$$\hat{\theta}_N = \arg\min_{\theta} \sum_{m,n=1}^{N} a_\theta(m-n)X(m)X(n).$$

If $\{X(n)\}$ is a Gaussian or a linear long-memory process, it was established under some regularity conditions that (see, e.g., Fox and Taqqu [35] and Giraitis and Surgailis [38])

$$N^{1/2}(\hat{\theta}_N - \theta) \overset{d}{\to} N(0, 4\pi W_\theta^{-1}).$$

where the matrix $W_\theta = (w_\theta(m, n))_{1 \leq m, n \leq P}$. Note that the standard $N^{1/2}$-convergence rate appears even
though \( \{X(n)\} \) has long memory. This is due to the dependence cancellation effect from the quadratic coefficient \( a_0(n) \).

On the other hand, Giraitis and Taqqu [39], considered \( X(n) = G(Y(n)) \), where \( \{Y(n)\} \) is long-memory Gaussian and the transformation \( G(\cdot) \) is restricted to be a polynomial by Giraitis and Taqqu [39] to avoid some technical difficulties. Define

\[
\rho_k = \frac{1}{k!} \sum_{n=0}^{\infty} \mathbb{E}\left[ \frac{d^k}{dx^k} G(x + Y(0)) \cdot G(x + Y(n)) \right]_{x=0} \nabla a_0(n)
= \sum_{m,n \geq 0, m+n=k} \frac{1}{m! n!} \sum_{r=-\infty}^{\infty} \mathbb{E}[G^{(m)}(Y(r)) \cdot G^{(n)}(Y(0))] \nabla a_0(r),
\]

where \( \nabla \) denotes the gradient with respect to \( \theta \). In particular,

\[
(34) \quad \rho_1 = 2 \sum_{n=-\infty}^{\infty} \mathbb{E}[G'(Y(n))G(Y(n))] \nabla a_0(n).
\]

Note that in the case \( G(x) = x \), namely, the Gaussian case, \( \rho_k = 0 \) for all \( k = 1, 2, \ldots \).

It was established in Corollary 2.1 of Giraitis and Taqqu [39] that under some regularity conditions, if \( \rho_1 \neq 0 \), then as \( N \to \infty \), we have

\[
(35) \quad N^{1-H}(\hat{\theta}_N - \theta) \xrightarrow{d} Z
\]

for some centered normal random vector \( Z \). Note that in (35) the convergence rate is the same as that of the sample mean in view of (1). Giraitis and Taqqu [39] also showed that if \( \rho_1 = 0 \) but some \( \rho_k \neq 0 \), then (35) needs to be modified resulting in limit theorem with a central and noncentral dichotomy similar to Theorem 2.6. See Theorem 2.3 and 3.1 of Giraitis and Taqqu [39].

Now we consider the instability issue. Here the role of Hermite (or power) rank is instead played by

\[
(36) \quad k = \inf\{m \in \mathbb{Z}_+ : \rho_m \neq 0\}.
\]

There is instability even in the Gaussian case where \( G(\cdot) \) is the identity, namely, \( G(x) = x \), and where then all \( \rho_k = 0 \). In that case, we would have (33), but by perturbing \( G(\cdot) \) slightly, we would get \( \rho_1 \neq 0 \) in (34), and thus we would have (35) instead of (33).

The preceding observation raises a question on the applicability of (33) in statistical inference. It turns out that the achievement of the parametric rate \( N^{1/2} \), or say the cancellation effect of the quadratic coefficient in (32), critically depends on the Gaussian or linear data-generating assumption, while a disturbance of such an assumption yields instead the rate \( N^{1-H} \), which is the usual slower rate of convergence under long memory. It is unclear whether similar instability issues occur in the semiparametric extensions of the Whittle estimator, for example, the local Whittle estimator (Künsch [53], Robinson [66]).

### 3.4 Nonparametric Estimation

In this section, we review briefly some nonparametric statistical studies under long memory involving the Hermite or power rank. Assume throughout that \( \{X(n)\} \) is a stationary long-memory process, typically specified by a Gaussian process, or a linear process, or a transformation of either (we call the model a Gaussian or linear subordination).

In the kernel smoother type nonparametric estimation procedures, a nonlinear transformation of the data is naturally involved. For example, the kernel density estimator of the probability density function \( f(x) \) is defined as

\[
(37) \quad \hat{f}(x) = \frac{1}{Nh} \sum_{n=1}^{N} K\left(\frac{x - X(n)}{h}\right), \quad x \in \mathbb{R},
\]

where \( N \) is the sample size, \( h > 0 \) is the bandwidth parameter, and \( K(\cdot) \) is a kernel satisfying \( \int_{\mathbb{R}} K(x) \, dx = 1 \). A number of studies have considered the asymptotic behavior of the estimator \( \hat{f}(x) \) as \( N \to \infty \) and \( h \to 0 \). See, for example, Cheng and Robinson [18], Csörgő and Mielniczuk [23] and Ho [47], Wu and Mielniczuk [84]. Another typical class of statistical procedures involving kernel smoothers are the nonparametric local regressions (e.g., Nadaraya–Watson estimator and local polynomial estimators). Some relevant work involving the ranks are Hidalgo [44], Csörgő and Mielniczuk [24], Masry and Mielniczuk [59], Guo and Kou [41].

We mention that under long memory, the asymptotic behavior of kernel smoothers can be quite different from the short-memory case. In particular, an interesting dichotomy phenomenon appears in the asymptotics depending on how fast the bandwidth \( b_n \) tends to 0 with respect to the Hurst index \( H \) of \( X(n) \). If \( b_n \) tends to 0 relatively slowly, one can have a very degenerate behavior such as the kernel density estimate \( \hat{f}(x) \) at different points of \( x \) becomes asymptotically perfectly correlated. See, for example, Csörgő [22] as well as Chapter 5.14 of Beran et al. [9].
Asymptotic results involving applying limit theorems with different ranks when studying these kernel smoother procedures are due more often to the assumption that \(X(n)\) is a transformation of a Gaussian or linear process, than due to the nonlinear transformation produced by \(K(\cdot)\) in (37). To obtain a higher-order rank for \(\hat{f}(x)\) when \(X(n)\) is Gaussian or linear, one has to be in very special situations, for example, when focusing on the asymptotic distribution of \(\hat{f}(x)\) in (37) at a fixed point \(x = x_0\) while assuming that the true density satisfies \(f'(x_0) = 0\) (see, e.g., Theorem 3 of Wu and Mielniczuk [84]). Similar considerations extend to other nonparametric procedures, for example, the spline regression under long-memory noise (Beran and Weiershäuser [12]).

### 3.5 Miscellaneous

Wavelets are useful tools for analyzing long-memory data due to their natural adaptivity to scaling. Limit theorems involving ranks were applied, for example, in Clausel et al. [20, 21], who studied the asymptotic behaviors of the wavelet coefficients and the wavelet estimation of Hurst index of the Gaussian subordination data.

Some other statistical studies involving higher-order ranks limit theorems are: bivariate U-processes (Lévy-Leduc et al. [55]), change-point test (Zhao, Tian and Xia [86], Dehling, Rooch and Taqqu [27]), goodness-of-fit test in regression Koul and Stute [52], normality test (Beran and Ghosh [10]), sign test (Psaradakis [65]), unit root test (Wu [82]).

### 4. EMPIRICAL EVIDENCE

In this section, we provide empirical evidence to support the preceding discussion of instability of ranks in the limit theorems under long memory.

Consider the rank of the quadratic transformation

\[
G(x) = x^2.
\]

It is always 2, in both the Gaussian and linear subordination context. This means that if \(\{X(n)\}\) is exactly a centered Gaussian or linear process with Hurst index \(H > 1/2\), then the Hurst index of the transformed series \(\{X(n)^2\}\) should be

\[
H_G = \max\left(\frac{1}{2}, 2H - 1\right) < H,
\]

in view of Theorem 2.6 and 2.15. Note that when \(H < 0.75\), the resulting Hurst index is always \(H_G = 0.5\) unless in the special case where the sum of covariances of all orders is zero (anti-persistency).

Here is the question: if \(\{X(n)\}\) is a real-life centered stationary data in which displays long memory, does one typically observe the decrease from \(H\) to \(H_G\) as in (38) when \(\{X(n)\}\) is replaced by \(\{X(n)^2\}\)? If our arguments in the previous sections make practical sense, then the time series \(\{X(n)^2\}\) should most likely still possess rank 1, which means that (38) should barely happen. To test this hypothesis, we design the following empirical study which involves \(\{X(n)\}\) and \(\{X(n)^2\}\). The design is explained in Remark 4.1 below.

#### Design of the study:

Suppose that we have a collection of \(M\) real-life centered stationary long-memory time series data

\[
\{X_m(n), n = 1, \ldots, N_m, m = 1, \ldots, M\},
\]

where \(n\) is the time index, and \(m\) is the data set index. For each \(m\), we perform the following analysis.

**Step 1** For each \(m = 1, \ldots, M\), center the data:

\[
X_m(n) \leftarrow X_m(n) - \frac{1}{N_m} \sum_{n=1}^{N_m} X_m(n).
\]

**Step 2** For each \(m = 1, \ldots, M\), obtain

the estimated Hurst index \(\hat{H}_m^{(1)}\) of

\[
\{X_m(n), n = 1, \ldots, N_m\}
\]

and

the estimated Hurst index \(\hat{H}_m^{(2)}\) of

\[
\{X_m(n)^2, n = 1, \ldots, N_m\}.
\]

**Step 3** For each \(m = 1, \ldots, M\), simulate \(R\) independent sequences of fractional Gaussian noise (increments of fractional Brownian motion):

\[
\{G_{mr}(n), n = 1, \ldots, N_m, r = 1, \ldots, R\},
\]

all with Hurst index \(\hat{H}_m^{(1)}\). Obtain

the estimated Hurst index \(\hat{H}_m^{(1)}\) of

\[
\{G_{mr}(n), n = 1, \ldots, N_m\}
\]

and

the estimated Hurst index \(\hat{H}_m^{(2)}\) of

\[
\{G_{mr}(n)^2, n = 1, \ldots, N_m\},
\]

for each \(r = 1, \ldots, R\).
Step 4 For each \( m = 1, \ldots, M \), compute
\[
\delta_m = \hat{H}_m^{(2)} - \max \left( \frac{1}{2}, 2\hat{H}_m^{(1)} - 1 \right)
\]
from the data, and compute
\[
\left\{ \delta_{mr} := \hat{H}_{mr}^{(2)} - \max \left( \frac{1}{2}, 2\hat{H}_{mr}^{(1)} - 1 \right), \right. \\
r = 1, \ldots, R \}
\]
from the simulated series. Then compute the relative number of times (percentile) that \( \delta_{mr} \) is less than or equal to \( \delta_m \) for \( r = 1, \ldots, R \), namely,
\[
P_m = \frac{1}{R} \# \{ \delta_{mr} : \delta_{mr} \leq \delta_m, r = 1, \ldots, R \} = \hat{F}_{m,R}(\delta_m),
\]
where \( \hat{F}_{m,R} \) is the empirical CDF of \( \{ \delta_{mr} : r = 1, \ldots, R \} \).

Step 5 Construct the following contrast group: for each \( m = 1, \ldots, M \), simulate a fractional Gaussian noise sequence
\[
\{ X_m^*(n), n = 1, \ldots, N_m^* \}
\]
with Hurst index randomly sampled from \( \{ \hat{H}_m^{(1)}, m = 1, \ldots, M \} \), and length \( N_m^* \) randomly sampled from \( \{ N_m, m = 1, \ldots, M \} \).

Then perform the preceding steps 1–4 replacing \( \{ X_m(n) \} \) by \( \{ X_m^*(n) \} \), from which one gets \( \hat{H}_m^{(1)*}, \hat{H}_m^{(2)*}, \delta_m^* \) and \( P_m^* \) that correspond to \( \hat{H}_m^{(1)}, \hat{H}_m^{(2)}, \delta_m \) and \( P_m \) respectively.

In our study we set \( R = 200 \).

Remark 4.1. We explain here the preceding study design. Recall that \( \hat{H}_m^{(1)} \) is the Hurst index estimate of the time series \( \{ X_m(n) \} \) and \( \hat{H}_m^{(2)} \) is the Hurst index estimate of the squared time series \( \{ X_m(n)^2 \} \). As mentioned before, the goal is to examine whether \( \hat{H}_m^{(1)} \) and \( \hat{H}_m^{(2)} \) behave according to (38). If they behave perfectly according to (38), then
\[
\delta_m = \hat{H}_m^{(2)} - \max \left( \frac{1}{2}, 2\hat{H}_m^{(1)} - 1 \right)
\]
should be zero. Both \( \hat{H}_m^{(1)} \) and \( \hat{H}_m^{(2)} \) are random and thus fluctuate as \( m \) varies. To get a reference point, we introduce a statistical contrast in Step 3, whereby we simulate \( R \) fractional Gaussian noises series and measure their Hurst indices \( \hat{h}_m^{(1)} \) and \( \hat{h}_m^{(2)} \): the first index is for fractional Gaussian noise and the second is for its square. Since these Hurst indices are obtained from fractional Gaussian noises, they indeed obey (38). We want to see how \( \delta_m \), which is measured from data, compares to the \( \delta_{mr} = \hat{h}_{mr}^{(2)} - \max \left( \frac{1}{2}, 2\hat{h}_{mr}^{(1)} - 1 \right) \) corresponding to fractional Gaussian noise. This leads us to focus on \( P_m \) instead of \( \delta_m \). One may view \( P_m \) as a “standardized” version of \( \delta_m \) with respect to the contrast distribution constructed from fractional Gaussian noise, which makes comparison across different data items (different \( m \)) more consistent. More technical explanations are given below.

Let \( F_m(x) \) be the CDF of the random \( \delta_m \). Then \( F_m(\delta_m) \) follows exactly a uniform distribution on \([0,1]\). If \( \{ X_m(n) \} \) were indeed generated by fractional Gaussian noise with true Hurst index \( \hat{H}_m^{(1)} \), then the empirical CDF \( \hat{F}_{m,R} \) in Step 4 is a good approximation of \( F_m \). Therefore, if \( \{ X_m(n) \} \) obeys (38) as the fractional Gaussian noise does, and \( \hat{H}_m^{(1)} \) is a reasonable estimate, then \( P_m = \hat{F}_{m,R}(\delta_m) \) in Step 4 is expected to follow a uniform distribution on \([0,1]\) approximately. On the other hand, if the \( \delta_m \) computed from the data makes the distribution of \( P_m = \hat{F}_{m,R}(\delta_m) \) skewed toward 1, then this indicates that \( \delta_m \) tends to be larger than \( \delta_{mr} \).

To account for the potential bias due to the estimation of the Hurst index, in Step 5 we replace our original data \( \{ X_m(n) \} \) by a second contrast group \( \{ X_m^*(n) \} \) made up of fractional Gaussian noise sequences with similar lengths and Hurst indices. After repeating the same procedure on this contrast group, we can then compare the distribution (histogram) of \( \{ P_m \} \) obtained from the original data with the distribution of \( \{ P_m^* \} \) obtained from the contrast group.

These designs may be regarded as simulation-assisted statistical tests where the null hypothesis is the relation (38).

Now we describe the data we use. The tree ring width in chronological order has been identified as one of the natural stationary time series data sets which exhibit long memory (see Mandelbrot and Wallis [58] and Pelletier and Turcotte [61]). Since the tree ring width is largely affected by environmental factors, which is explored in dendrochronology (see Schweingruber [70]), it also reflects the long-memory stationary fluctuation of the ecological systems. We shall use the data compiled by the International Tree-Ring Data Bank (ITRDB, ftp://ftp.ncdc.noaa.gov/pub/data/paleo/treering/chronologies/) collected from Africa.
the wavelet-type estimators (see, e.g., Faÿ et al. [34]). To minimize finite-sample bias, these methods typically involve complicated choice of some tuning parameters. Since our study design has taken into account the potential bias of the estimator, we shall stick to the three more elementary estimators aforementioned. For the variance aggregation estimator and the local periodogram regression (GPH estimator), we use the implementation by Chu Chen (http://www.mathworks.com/matlabcentral/fileexchange/19148-hurst-parameter-estimate, and we use the default parameter settings); For the local Whittle estimate, we use the implementation by Katsumi Shimotsu (http://shimotsu.web.fc2.com/Site/Matlab_Codes.html), in which case we choose the frequency cutoff threshold to be $[N^{2/3}]$ with $N$ being the length of the time series).

Observations:

The graphs in the right-hand side of Figures 2, 3 and 4 are as expected, namely, corresponding roughly to a uniform distribution. This indicates that the procedure described in the study is reasonable. In fact, the median of $P_m$ is roughly 50% as it should be (see Table 1). As mentioned below, there may be a small bias when using the Local Periodogram Regression method [Figure 3 (right)]. See also Taqqu and Teverovsky [77] for an empirical discussion of Whittle-type estimators.

Table 1 summarizes some key statistics of the analysis based on the three different estimators. One can see that for all three estimators, the median of $\delta_m$ is consis-
ently smaller than that of the contrast $\delta^{*}_{m}$. The median of $P_{m}$ is significantly smaller than that of the contrast $P^{*}$. Figures 2, 3 and 4 plot the histograms of $\{P_{m}\}$ and $\{P^{*}\}$ obtained via the three different estimators. Their results are similar: while $\{P^{*}\}$ are roughly uniformly distributed as expected, the histogram of $\{P_{m}\}$ is severely skewed toward 1. The contrast in the skewness shows that the $\delta_{m}$ computed from the tree ring data tends to be larger than the $\{\delta_{mr}\}$ computed from the fractional Gaussian noise. In other words, in the case of tree ring data, the Hurst index does not tend to decrease as much after squaring as the case of fractional Gaussian noise.

As mentioned in Remark 4.1, if the Hurst index estimate is unbiased, $P^{*}_{m}$ is expected to approximately follow a uniform distribution on $[0, 1]$, so that the median is close to $1/2$. However, the estimation bias of Hurst index could distort this uniformity. Indeed, in the Local Periodogram Regression case, the median of $P^{*}_{m}$ is 63.5%. But this is still in sharp contrast with the corresponding median of $P_{m}$ which is 86.25% and hence significantly larger. This indicates that the data is not behaving like fractional Gaussian noise. Thus our design is effective despite the bias inherent in the estimation method.

**Remark 4.2.** From the analysis above, we conclude that relation (38), or more generally (11), may not make good prediction on real-life data. We note, however, that the estimated Hurst index $\hat{H}^{(2)}_{m}$ of $\{X_{m}(n)^{2}\}$ tends to be somewhat smaller than the estimated Hurst index $\hat{H}^{(1)}_{m}$ of $\{X_{m}(n)\}$, although for the contrast group $\{X^{*}(n)\}$ the decrease from $\hat{H}^{(1)*}_{m}$ to $\hat{H}^{(2)*}_{m}$ is more significant. See Figure 5. A possible explanation is that although $\{X_{m}(n)^{2}\}$ actually possesses rank 1 and thus has the same Hurst index as $\{X_{m}(n)\}$, many of the $\{X_{m}(n)\}$ may be close to a Gaussian (or linear) process. So they tend to exhibit somewhat the
relation (38) when the sample size is moderate. See Bai and Taqqu [6] for an analysis of the interplay between the rank instability effect and the sample size.

Remark 4.3. As a reviewer pointed out, another explanation of the observations found in the study is that the data originally follows a model with a rank higher than 1, in which case squaring does not necessarily lead to a higher-order rank. Although this explanation is allowable in theory, it is less natural than the instability explanation. The reviewer’s explanation relies on assuming a special model: the transformation of a Gaussian or linear process with higher-order rank, while ours indicates that a slight perturbation makes the formula (38) unrealistic in practice.

5. Stability of Limit Theorems Under Weak Dependence

In this section, we demonstrate that the instability phenomenon appearing in the limit theorems under long memory does not typically occur in the short-memory case. This is important because it shows that the transformation considered as “perturbation” in the previous section usually does not make any qualitative difference in short-memory situations and hence may be safely negligible in large sample inference.

There are many ways to mathematically characterize weak dependence. For an introduction to various notions of weak dependence of stationary processes and corresponding limit theorems, we refer to Doukhan [32]. In this section, we shall mainly look at the following three as examples:

1. Fast-decaying mixing coefficients under strong mixing conditions;
2. Fast decaying covariance function in Gaussian subordination model (Theorem 5.2);
3. Fast decaying physical dependence measure of Wu [81] in Bernoulli shift models.

The first is by far the most widely used notion for weak dependence which applies to very general stationary processes. The second is mentioned due to its close connection to the considerations in Section 2.1. The third is a convenient criterion under the Bernoulli shift framework which covers a wide range of concrete statistical models.

5.1 Strong Mixing Conditions

Suppose that \( \{Y(n)\} \) is a stationary process with \( \mathbb{E}[Y(n)] = 0 \) and \( \text{Var}[Y(n)] = 1 \). Define the \( \sigma \)-field \( \mathcal{F}_n^b = \sigma \{ Y(n) : a \leq n \leq b \} \), where \( -\infty \leq a \leq b \).

| Estimator                | Selected number \( M \) | Median \( \delta_m \) | Median \( \delta^*_m \) | Median \( P_m \) | Median \( P^*_m \) |
|--------------------------|--------------------------|------------------------|------------------------|-----------------|-----------------|
| Variance Aggregation     | 1250                     | 0.0786                 | 0.0104                 | 80.50%          | 51.00%          |
| Local Periodogram Regression | 658                     | 0.0921                 | -0.0204                | 86.25%          | 63.50%          |
| Local Whittle            | 908                      | 0.0496                 | -0.0162                | 80.50%          | 52.50%          |
Given two σ-fields $A, B$, one can define the following measure of dependence

$$\alpha(A, B) = \sup \{ \left| P(A \cap B) - P(A)P(B) \right| : A \in A, B \in B \}.$$  

(39)

Then the $\alpha$-mixing coefficient of $\{X(n)\}$, first introduced in Rosenblatt [67], is defined as

$$\alpha_Y(n) = \alpha(F_{-\infty}^0, F_n^\infty).$$

When $\alpha_Y(n) \to 0$ as $n \to \infty$, we say that $\{Y(n)\}$ is strong mixing. If one assumes that $\alpha_Y(n)$ decays to zero fast enough together with some other regularity conditions, then a central limit theorem for $X(n)$ can be established. We state, as an example, the following central limit theorem due to Ibragimov [49] and Herrndorf [43].

**Theorem 5.1.** If $\mathbb{E}[|Y(n)|^{2+\delta}] < \infty$ for some $\delta > 0$ and

$$\sum_{n=1}^{\infty} \alpha_Y(n)^{\delta/(2+\delta)} < \infty,$$  

(40) then

$$\frac{1}{\sqrt{N}} \sum_{n=1}^{[Nt]} (Y(n) - \mathbb{E}Y(n)) \Rightarrow \sigma B(t),$$

where $B(t)$ is a standard Brownian motion, $\Rightarrow$ stands for weak convergence in $D[0, 1]$, and

$$\sigma^2 = \sum_{n=-\infty}^{\infty} \text{Cov}[Y(n), Y(0)].$$

Now consider the transformation

$$X(n) = F(Y(n), \ldots, Y(n-l)).$$

Let us compare $\alpha_X$ and $\alpha_Y$. Since $X(n) \in F_{n-l}^n$, it is easily deduced that for $n > l$, the $\alpha$-mixing coefficient of $\{X(n)\}$ satisfies

$$\alpha_X(n) \leq \alpha_Y(n-l).$$  

(41)

The relation (41) means that the dependence measured by the $\alpha$-mixing coefficient after the perturbing transform $F(\cdot)$ cannot exceed that of the original process $Y(n)$ (up to a fixed lag $l$). In particular, relation (40) holds for $\alpha_X(n)$. One then only needs $\mathbb{E}[|X(n)|^{2+\delta}] < \infty$ [which is the case if $F(\cdot)$ has at most linear growth] for Theorem 5.1 to hold.
There are different mixing coefficients than \( \alpha(n) \), obtained by modifying the measure of dependence between the \( \sigma \)-fields in (39), for example, the \( \phi \)-mixing coefficient defined through
\[
\phi(A, B) = \sup \{|P(A|B) - P(A)| : A \in A, B \in B, P(B) > 0\},
\]
the \( \rho \)-mixing coefficient defined through
\[
\rho(A, B) = \sup \{\text{Corr}(X, Y) : X \in L^2(A), Y \in L^2(B)\},
\]
and so on. In general, as long as a dependence measure \( m(\cdot, \cdot) \) is nonincreasing with respect to set inclusion and the mixing coefficient is defined as \( m(n) = m(F_{-\infty}^0, F_n^{\infty}) \), then a relation such as (41) always holds.

Hence, the central limit theorems under strong mixing conditions is robust against a transformation perturbation.

5.2 Gaussian Subordination

Let \( \{Y(n)\} \) be a stationary Gaussian process, and let
\[
X(n) = F(Y(n), \ldots, Y(n-l)).
\]
When the covariance function of \( Y(n) \) decays fast enough, a central limit theorem always holds for \( X(n) \). In particular, we have the following result which is a consequence of Ho and Sun [46].

**THEOREM 5.2.** Suppose that \( \sum_{n=-\infty}^{\infty} \text{Cov}[Y(n), Y(0)] < \infty \) and
\[
\sum_{n=-\infty}^{\infty} |\text{Cov}[Y(n), Y(0)]| < \infty. \tag{42}
\]
Then one has
\[
\frac{1}{\sqrt{N}} \sum_{n=1}^{[Nt]} (X(n) - \mathbb{E}X(n)) \overset{f.d.d.}{\longrightarrow} \sigma B(t),
\]
where \( B(t) \) is a standard Brownian motion and
\[
\sigma^2 = \sum_{n=-\infty}^{\infty} \text{Cov}[X(n), X(0)].
\]

Theorem 5.2 directly expresses the robustness of the central limit theorem against transformation perturbation when the short-memory condition (42) is imposed on \( Y(n) \).

5.3 Bernoulli Shift

Let \( \{\varepsilon_i\} \) be an i.i.d. sequence of random variables with mean 0 and variance 1. Consider the Bernoulli shift model
\[
Y(n) = G_Y(\varepsilon_n, \varepsilon_{n-1}, \ldots), \tag{43}
\]
where \( G_Y \) is a nonrandom measurable function. This specification covers not only the causal linear process (17), but also many nonlinear time series models obtained as solutions of difference equations involving \( \varepsilon_i \).

Wu [81] introduced the following so-called **physical dependence measure** for a process \( \{Y(n)\} \) specified by (43). Let \( \varepsilon^*_0 \) be a random variable independent of \( \{\varepsilon_i\} \) and having the same distribution as \( \varepsilon_0 \). Define
\[
\delta^X_2(n) = \|G_Y(\varepsilon_n, \ldots, \varepsilon_1, \varepsilon_0, \varepsilon_{-1}, \ldots) - G_Y(\varepsilon_n, \ldots, \varepsilon_1, \varepsilon^*_0, \varepsilon_{-1}, \ldots)\|_{L^2(\Omega)}. \tag{44}
\]
If (43) is interpreted as a nonlinear system with input \( \{\varepsilon_n\} \) and output \( \{Y(n)\} \), then \( \delta^X_2(n) \) in (44) measures the influence of the lag-\( n \) input \( \varepsilon_0 \) on the current output \( Y(n) \).

With \( \delta^X_2(n) \), one can state the following central limit theorem, which is a consequence of Theorems 1 and 3 of Wu [81].

**THEOREM 5.3.** Suppose that
\[
\sum_{n=1}^{\infty} \delta^X_2(n) < \infty. \tag{45}
\]
Then one has
\[
\frac{1}{\sqrt{N}} \sum_{n=1}^{[Nt]} (X(n) - \mathbb{E}X(n)) \overset{f.d.d.}{\longrightarrow} \sigma B(t), \quad t \geq 0,
\]
where \( B(t) \) is a standard Brownian motion, and
\[
\sigma^2 = \sum_{n=-\infty}^{\infty} \text{Cov}[X(n), X(0)].
\]

**REMARK 5.4.** The criterion (45) is typically easier to check for a specific Bernoulli shift model than the criteria based on strong mixing conditions (see Theorem 5.1), while still providing numerous statistical applications.

Now we consider the transformation perturbation. Let
\[
X(n) = F(Y(n), \ldots, Y(n-l+1))
\]
\[
= : G_X(\varepsilon_n, \varepsilon_{n-1}, \ldots).
\]
We need to assume some smoothness condition (compare with the arguments of Claim 2.11) on the perturbation function \( F(x_1, \ldots, x_l) \). In particular, suppose that \( F(\cdot) \) is Lipschitz, that is,
\[
|F(x_1, \ldots, x_l) - F(y_1, \ldots, y_l)| \leq C_F \sum_{i=1}^{l} |x_i - y_i|, \tag{46}
\]
for some constant \( C_F \geq 0 \).
Setting \( \varepsilon_n = (\varepsilon_n, \ldots, \varepsilon_1, \varepsilon_0, \varepsilon_{-1}, \ldots) \) and \( \varepsilon_n^* = (\varepsilon_n, \ldots, \varepsilon_1, \varepsilon_{*0}, \varepsilon_{-1}, \ldots) \), one has by (46) that
\[
\left| G_X(\varepsilon_n) - G_X(\varepsilon_n^*) \right| \\
\leq C_F \sum_{i=0}^{l-1} \left| G_Y(\varepsilon_{n-i}) - G_Y(\varepsilon_{n-i}^*) \right|.
\]
Therefore, if \( \delta^X_2(n) \) and \( \delta^Y_2(n) \) are the physical dependence measures of \{X(n)\} and \{Y(n)\} respectively, then
\[
\delta^X_2(n) = \left\| G_X(\varepsilon_n) - G_X(\varepsilon_n^*) \right\|_{L^2(\Omega)} \\
\leq C_F \sum_{i=0}^{l-1} \delta^Y_2(n - i).
\]
Hence if \{Y(n)\} satisfies the short-memory condition
\[
\sum_{n=1}^{\infty} \delta^Y_2(n) < \infty,
\]
then so does \{X(n)\}. This shows the robustness of Theorem 5.3 against a perturbation by any Lipschitz transformation.

**Remark 5.5.** The proof of Theorem 5.3 is based on a martingale difference approximation method and resorts to the martingale difference central limit theorem. We note, however, that the martingale difference central limit theorem is itself not robust against transformation, since the martingale difference structure in general can be easily disturbed by a transformation. For example, in the stochastic volatility-type models, for instance, the LARCH model (Giraitis et al. [37]), the return sequence \( X(n) \) is a martingale difference, while \{X(n)\} can exhibit long memory (see Beran et al. [9], Chapter 4.2.8).

**Remark 5.6.** Using similar arguments, one can show that the \( \theta \)-weak dependence criterion (whose definition involves bounded Lipschitz transformation) introduced by Doukhan and Louhichi [33], enjoys a robustness against bounded Lipschitz transformations.

### 6. Conclusion and Suggestions

In this paper, we discussed the instability issue of Hermite rank and other related ranks appearing in limit theorems under long memory. We argued that a rank greater than 1 can be disturbed by a transformation and only a rank equal to 1 is stable. We provided empirical evidence supporting this argument. Such an instability feature has important statistical implications. In particular, assuming a higher-order rank when it is really not there may result in underestimating the order of fluctuation of the statistic of interest.

To address this issue we briefly indicate here some suggestions for performing valid inference. As illustrated, particularly in Section 3, one may adopt the assumption that the rank is always 1, regardless of any nonlinear transformation resulting from the statistical procedure. Here the rank should be understood in a generalized sense, taking into account situations as (36). Some studies have implicitly done so, although without giving an explanation (see, e.g., Beran [8] and Shao [72]). Recently Beran, Möhrle and Ghosh [11] designed a statistical test based on resampling to distinguish Hermite rank 1 and a higher-order Hermite in the model (14).

Another appealing way out, is to redesign the statistical procedure in a way as to avoid using the fixed-rank limit theorems for inference directly. This may be achieved by combining resampling method (see, e.g., Hall, Jing and Lahiri [42], Nordman and Lahiri [60], Zhang et al. [85]), Bai and Taqqu [5]), together with suitable self-normalization technique (see, e.g., Shao [71, 72]). We refer the reader to Jach, McElroy and Politis [50], Betken and Wendler [13] and Bai, Taqqu and Zhang [7] for approaches of this type.

### APPENDIX: NONINSTANTANEOUS TRANSFORMATION OF THE GAUSSIAN

Let \( \{Y(n)\} \) be a standardized stationary long-memory Gaussian process with Hurst index \( H \). We extend here the discussion on instantaneous transformation (14) to the noninstantaneous transformation
\[
X(n) = F(Y(n), Y(n - 1), \ldots, Y(n - l)),
\]
where \( X(n) \in L^2(\Omega) \) and \( l \) is a finite positive integer. Since the noninstantaneous case is much less treated in the literature, we shall introduce in this section the relevant results in Dobrushin and Major [31], and show that the arguments developed in Section 2.1 continue to be valid.

It is well known that the Gaussian \( Y(n) \) admits the spectral representation (see, e.g., Dobrushin and Major [31])
\[
Y(n) = \int_{(-\pi, \pi]} e^{inx} W_Y(dx),
\]
where \( W_Y(dx) \) is a complex-valued Gaussian measure satisfying
\[
\mathbb{E}\left| W_Y(dx) \right|^2 = F_Y(dx)
\]
and \( F_Y(\cdot) \) is the spectral distribution\(^5\) of \( Y(n) \). Then \( X(0) \) has the following Wiener–Itô expansion (see Dobrushin and Major [31], formula (6.1), or Janson [51], Theorem 7.61):

\[
X(0) - \mathbb{E}X(0) = \sum_{m=1}^{\infty} \int_{(-\pi, \pi]^m} m! \|\alpha_m\|^2_{L^2(\mathbb{R}, \mathcal{F}_Y)} \alpha_m(x_1, \ldots, x_m) \right. \\
\left. \left. \cdot W_Y(dx_1) \cdots W_Y(dx_m), \right.
\]

where the double prime ″ indicates the exclusion of the hyper-diagonals \( x_p = \pm x_q \) in the multiple stochastic integral. Here \( \alpha_m(\cdot)'s \) are a.e. unique complex-valued functions in satisfying

\[
\alpha_m(x_1, \ldots, x_k) = \overline{\alpha_m(-x_1, \ldots, -x_m)}
\]

and

\[
\sum_{m=1}^{\infty} m! \|\alpha_m\|^2_{L^2((\mathbb{R}, \mathcal{F}_Y)} < \infty,
\]

where

\[
\|\alpha_m\|^2_{L^2((\mathbb{R}, \mathcal{F}_Y)} = \int_{(-\pi, \pi]^m} |\alpha_m(x_1, \ldots, x_m)|^2 F_Y(dx_1) \cdots F_Y(dx_m).
\]

The Hermite rank of \( X(n) \) [or say the Hermite rank of \( F(\cdot) \) with respect to \( \{Y(n)\} \)] is defined as

\[
\inf\{m \geq 1 : \|\alpha_m\|^2_{L^2((\mathbb{R}, \mathcal{F}_Y)} \neq 0\}.
\]

The Hermite rank in (51) is also equal to (see Dobrushin and Major [31], Remark 6.3)

\[
\inf\{m \geq 1 : \mathbb{E}\left[(X(0) - \mathbb{E}X(0))^m\right] \neq 0\}
\]

for some \( n \in \mathbb{Z} \).

This should be compared to (7).

By Remark 6.1 of Dobrushin and Major [31], the a.e. unique function \( \alpha_m(\cdot) \) can further be chosen to be continuous, which we shall assume throughout below. We are now ready to state the following generalization of Theorem 2.6, which follows from Dobrushin and Major [31], Theorem 3, Remark 6.3 and Remark 6.4.

**Theorem A.1.** Suppose that \( X(n) = F(Y(n), \ldots, Y(n-l)) \), and that the Hermite rank in the sense of (51) is \( k \), and that the Hurst index \( H \) of \( \{Y(n)\} \) satisfies

\[
H > 1 - \frac{1}{2k}.
\]

\(^5\)Do not confuse \( F_Y \) in (49) with \( F \) in (47).

Suppose also that \( \alpha_k(\cdot) \) in (50) satisfies

\[
\alpha_k(0, \ldots, 0) \neq 0.
\]

Then \( \{X(n)\} \) has long memory with Hurst index

\[
H_F = (H - 1)k + 1 \in \left(\frac{1}{2}, 1\right).
\]

Furthermore, as \( N \to \infty \), we have

\[
\frac{1}{N^{H_F}} \sum_{n=1}^{[N]} (X(n) - \mathbb{E}X(n)) \Rightarrow c\alpha_k(0, \ldots, 0) Z_{H_F, k}(t),
\]

for some \( c \neq 0 \), where \( Z_{H_F, k}(t) \) is the Hermite process in (13).

**Remark A.2.** In contrast to Theorem 2.6 where the constant \( c \) in (12) is always nonzero, in the non-instantaneous case we need to assume in addition the condition (53). If \( \alpha_k(0, \ldots, 0) = 0 \), then (54) tells nothing more than that the normalization \( N^{-H_F} \) is too strong. In this case, terms with order greater than \( k \) may contribute to the asymptotic distribution as well. For example, if in (47) we let

\[
X(n) = H_1(Y(n)) - H_1(Y(n - 1)) + H_2(Y(n))
\]

\[
= Y(n) - Y(n - 1) + Y(n)^2 - 1.
\]

Using the spectral representation (48) and Major [57] Theorem 4.3, we have

\[
X(0) = \int_{(-\pi, \pi]} (1 - e^{-ix}) W_Y(dx)
\]

\[
+ \int_{(-\pi, \pi]^2} W_Y(dx_1) W_Y(dx_2)
\]

so that \( \alpha_1(x) = 1 - e^{-ix} \) and \( \alpha_1(0) = 0 \). On the other hand, the Hermite rank of \( X(n) \) is \( k = 1 \) in view of (50). Now

\[
\sum_{n=1}^{N} X(n) = Y(N) - Y(0) + \sum_{n=1}^{N} H_2(Y(n)).
\]

Since \( Y(n) \) is stationary, \( N^{-H} [Y(N) - Y(0)] \xrightarrow{P} 0 \), and thus only the term \( \sum_{n=1}^{N} H_2(Y(n)) \) contributes to in the limit. Hence the limit of suitably normalized \( \sum_{n=1}^{N} X(n) \) can be either a Brownian motion if \( H \leq 3/4 \) or a Hermite process of order 2 if \( H > 3/4 \) in view of Theorem 2.6.

**Remark A.3.** Now arguing as in Section 2.1, one notes that a Hermite rank higher than 1 in this non-instantaneous context is also unstable. Recall that the
role of $F(\cdot)$ in (47), as in Section 2.1, is to account for an uncontrollable perturbation of the Gaussian model. Suppose that $G(\cdot)$ is a function determined by the statistical procedure of interest. Then one can formulate a statement parallel to Claim 2.11. So the part of Theorem A.1 which is most likely of statistical relevance is just the case where $Y(n)$ is a Gaussian stationary noise and $G(\cdot)$ is a finite-dimensional multivariate function of the observed time series $\{X(n)\}$, for example, $G(X(n), \ldots, X(n-p)) = X(n)X(n-p)$, a term which appears in the sample covariance.

Arguing as in Claim 2.11, condition (53) should be expected to typically hold in practice.

**Remark A.4.** Using the full generality of Theorem 3 of Dobrushin and Major [31], it is even possible to consider the case $l = \infty$ in (47), namely, including dependence on the infinite past. In this case, however, one encounters major technical difficulties since $F(\cdot)$ with $l = \infty$ may alter the long-memory property of $Y(n)$, for example, if $F(\cdot)$ is a linear filter with a slow power-law decay (see, e.g., Section 2.5). On the other hand, one may be satisfied with the restriction to $l < \infty$ since $F(\cdot)$ has been introduced only to account for a small perturbation of the Gaussian model, in which case the argument of $F(\cdot)$ is not expected to stretch to the infinite past.

**Remark A.5.** This discussion can also be extended to the case where $Y(n)$ is a vector-valued Gaussian stationary noise and $X(n)$ is also vector-valued. See, for example, Denaranjo [30] and Arcones [1].

**Remark A.6.** We mention that the extension of Theorem 2.15 to noninstantaneous transformation of linear processes, that is, an analog of Theorem A.1 when $X(n)$ is linear, is still open. Only central limit theorems involving noninstantaneous filter of linear processes have been considered (see Wu [80] and Cheng and Ho [19]).
