THE $RO(C_4)$ INTEGRAL HOMOLOGY OF A POINT

NICK GEORGAKOPOULOS

Abstract. We compute the $RO(C_4)$ integral homology of a point with complete information as a Green functor, and we show that it is generated, in a slightly generalized sense, by the Euler and orientation classes of the irreducible real $C_4$-representations. We have devised a computer program that automates these computations for groups $G = C_p$, and we have used it to verify our results for $G = C_4$ in a finite range.

1. Introduction

In the solution of the Kervaire invariant one problem [HHR16], the very first step is obtaining partial information about the $RO(C_8)$ integral homology of a point,

$$\mathbb{L}^C_{\mathbb{S}_8}(H\mathbb{Z}) = \mathbb{H}^C_{\mathbb{S}_8}(S^0; \mathbb{Z}).$$

The vanishing of these homologies for certain virtual representations $\star$ is used to prove the Gap Theorem. In [HHR17], they perform a similar computation in the more tractable $C_4$ case, obtaining more complete information for the slice spectral sequence they consider. However, because they are interested only in the integer-graded part of that spectral sequence, they only compute $\mathbb{H}^C_{\mathbb{S}_8}(S^0; \mathbb{Z})$ for $\star = k + r\rho$ where $k, r \in \mathbb{Z}$ and $\rho$ is the regular $C_4$-representation.

In this paper, we compute $\mathbb{H}^C_{\star}(S^0; \mathbb{Z})$ for all possible $\star$, as a Green functor. This means that in addition to all the groups $H^H_V(S^V; \mathbb{Z})$ for $V$ a real $C_4$ representation and $H$ a subgroup of $C_4$, together with their restrictions and transfers, we also compute the multiplicative structure which comes from the fact that $HZ$ is a $C_4$-ring spectrum.

The group $C_4$ has two non-trivial irreducible real representations, the 1-dimensional sign representation $\sigma$ and the 2-dimensional representation $\lambda$ (rotation by $\pi/2$ degrees). Therefore, we are in effect computing the Mackey functors $\mathbb{H}^C_k(S^{n\sigma+m\lambda}; \mathbb{Z})$ for $k, n, m \in \mathbb{Z}$ and $n, m \geq 0$. When both signs in $S^{n\sigma+m\lambda}$ are positive, we have an explicit and simple equivariant cellular decomposition for the space $S^{n\sigma+m\lambda}$ and we can compute the homology using the cellular chain complex $\bigoplus S^{n\sigma+m\lambda}$. When both signs are negative, we can appeal to Spanier Whitehead Duality:

$$\mathbb{H}^C_k(S^{-n\sigma-m\lambda}) = \mathbb{H}^{-k}_{C_4}(S^{n\sigma+m\lambda})$$

and this is the cohomology of the cochain complex $\bigoplus S^{n\sigma+m\lambda}$ dual to the chains $\bigoplus S^{n\sigma+m\lambda}$ we had before.

The more difficult part of the computation is when we have opposite signs, such as $\mathbb{H}^C_k(S^{n\sigma-m\lambda}; \mathbb{Z})$. In this case, we could in principle work with the box
product of chain complexes
\[ C^\ast S^m \ast \boxtimes S^n \ast \]
but these complexes get intractably large for calculations by hand as \( n, m \) get large. In place of that, we instead make use of three algebraic spectral sequences associated to these complexes: Two Atiyah-Hirzebruch spectral sequences and a Kunneth spectral sequence. Comparison of these three allows us to get the answer through fairly intuitive (if lengthy) arguments. A complication is that everything needs to be performed on the Mackey functor level: for example, the \( \text{Tor} \) terms in the Kunneth spectral sequence are computed in the symmetric monoidal category of \( \mathbb{Z} \)-modules.

The main result of this paper is that \( \pi C^4 \ast(H\mathbb{Z}) \) is generated, in a generalized sense, by the Euler and orientation classes associated to \( \sigma, \lambda \). These classes, under the operations of multiplication, division (see subsection 4.1 for the precise meaning of “division”), restriction and transfer, don’t quite generate the entire \( \pi C^4 \ast(H\mathbb{Z}) \), missing the generator of \( H^C_3(S^{-2\lambda}) = \mathbb{Z}/4 \). However, it turns out that this \( \mathbb{Z}/4 \) fits in a short exact sequence of abelian groups
\[ 0 \to \mathbb{Z}/2 \to \mathbb{Z}/4 \to \mathbb{Z}/2 \to 0 \]
where the \( \mathbb{Z}/2 \)'s are obtainable using just the Euler and orientation classes. So if we include this group extension into our list of “operations”, then the closure of the Euler and orientation classes under said operations is the entire \( \pi C^4 \ast(H\mathbb{Z}) \).

At this point, we should mention earlier work by Zeng on this topic. [Zeng17] calculates the integer coefficient \( RO(C_{p^2}) \)-graded homology of a point for all primes \( p \), using the associated Tate-square diagram as opposed to the cellular chains approach we use here. Our results agree with his in the case \( p = 2 \) (modulo notational differences), but we hope this write-up provides a more comprehensive analysis of this case, while also offering a detailed discussion of the subtleties involved in this computation, many of which are relevant in correctly interpreting the results of the computation (c.f. subsection 4.2).

Another novelty in our work is the computerization of this computation, not just for \( G = C_4 \) but indeed for any \( G = C_{p^n} \). We have devised a computer program that automatically produces the answer for both the additive and multiplicative structures of \( \pi G \ast(H\mathbb{Z}) \) or more generally \( \pi G \ast(HR) \) where \( R \) is a user specified ring (such as \( \mathbb{F}_p \)). It can also compute the Massey products present in \( \pi G \ast(HR) \) together with their indeterminacy. Of course the program can only work in a finite range, i.e. it can produce the answer for \( SV \) where the dimension of \( V \) is bounded.

Therefore, while the code can’t completely replace the proof-based work, at the very minimum it’s a powerful verification tool. For example, it was able to spot a few edge cases where mistakes were present in an early draft of this paper. The other advantage is scalability: determining \( \pi C_{p^n} \ast(H\mathbb{Z}) \) by hand for \( n \geq 3 \) is significantly more laborious than the \( n = 2 \) case as there are more representations to contend with. But using the computer program, we can quickly and easily
compute $π^{C_p^n}(H\mathbb{Z})$ in a large range and get a good grasp for what the answer should be.

As for the organization of this paper, section 2 offers a brief introduction of how our program works. The rest of the paper is completely independent of that.

Section 3 includes the 16 Mackey functors that appear in $H^C_4(S^{nσ±mλ})$ and their notation used throughout this paper. Remarkably we can get a non-cyclic answer for $H^C_k(S^{nσ−mλ})$ but only for even $n ≥ 4$.

Section 4 expounds on how the Euler and orientation classes generate $π^{C_4}(H\mathbb{Z})$ and how all relations can be effectively reduced to a single one, the “Gold Relation”.

Section 5 includes the complete determination of the Green functor $π^{C_4}(H\mathbb{Z})$ in the form of 8 readily usable tables.

Section 6 summarizes the theoretical framework of our computations.

The last five sections include the proofs of our results and make up the bulk of this paper. The final one is an Appendix devoted to proving that the Gold relation generates all other relations.

We plan to investigate the $C_8$ case, and whether $π^{C_8}(H\mathbb{Z})$ is generated by the Euler and orientation classes (in the same generalized sense) in a sequel. If true, it would raise the question whether this continues to happen for $G = C_{2n}$, $n ≥ 4$. We also aim to investigate the case of $\mathbb{F}_2$ coefficients and any interesting Massey products that arise, now aided by our computer program.

The computational aspects of equivariant homotopy theory have been much less explored than their nonequivariant counterparts, and that’s partly due to the greater complexity of the algebra involved. This complexity is not just a technicality, as it’s reflected in the answers retrieved by the calculations. By computerizing this algebra we can drastically expand the known calculations while reducing the human work required. Currently, our computer program can do the $G = C_{p^n}$ case but in the future we expect to extend this to arbitrary finite abelian groups and possibly to certain nonabelian groups. The source code is publicly available here, where the interested reader can not only inspect it, but also contribute to its improvement and expansion, which we highly encourage.

Acknowledgement. We want to thank Mingcong Zeng for carefully reading an earlier draft of this paper, helping us compare our computations with his, and for pointing out a subtlety in a certain relation of the multiplicative structure (c.f. end of subsection 4.2).

2. The Computer Program

The computations in this paper rely on filtering box products such as

$$C_4(S^{nσ−mλ}) = C_4(S^{nσ}) \boxtimes C_4(S^{-mλ})$$

in different ways and comparing the resulting spectral sequences (here and always, $n, m$ are nonnegative integers). Ideally, we would be working directly with that box product, but there are two major complications that prohibit this: Firstly, the box product of Mackey functors is not the level-wise tensor product. Instead, only the bottom level (corresponding to the orbit $G/e$) can be obtained as the tensor product, while all the higher levels are obtained by transferring (our chains
consist solely of free Mackey functors). Secondly, the bottom level tensor product itself gets arbitrarily large as we increase $n, m$, making it impractical to compute with it. The extra complexity is reflected in the fact that the results for representations $m\lambda - n\sigma$ and $n\sigma - m\lambda$ (subsections 5.5 to 5.8) are more involved than those for $n\sigma + m\lambda$ and $-n\sigma - m\lambda$ (subsections 5.1 to 5.4); after all, we need not use any box products for the representations of the form $n\sigma + m\lambda$ and $-n\sigma - m\lambda$.

While computing the box product of these chain complexes by hand is very impractical, a computer can do it efficiently. The idea is that our chains consist of solely free Mackey functors over $\mathbb{Z}$, so every differential can be completely described by a matrix with integer entries. The operations of transfer, restriction and group action can all be done algorithmically for free Mackey functors, and their effect can be described in terms of these matrices. Similarly, the tensor product can also be computed algorithmically, and then the box product is just obtained by transferring it to higher levels. At the final step, we need to take homology and that can be achieved via the classical Smith Normal Form algorithm over $\mathbb{Z}$.

There are a few more technicalities in the algorithm that we haven’t addressed here, but once these details are dealt with, this process allows us to algorithmically compute the additive structure of the $RO(G)$ homology, in any given range for our representations (for $G = C_4$, this amounts to a given range for $n, m$).

For the multiplicative structure we need to be able to compute the product of any two generators. Just like with tensor products, this can be directly performed only on the bottom level. If the generators live in a higher level, the idea is to first restrict them to the bottom level, multiply these restrictions, and then invert the restriction map. This is possible because in free Mackey functors, restrictions are injective, and our chain complexes consist exclusively of such Mackey functors.

So far we have enough information to verify the multiplicative structure as it appears in section 5, but not automatically compute it. In other words, the expressions of the generators in section 5 need to be known a-priori and then the program can prove them in a user-specified range. But there is a final algorithm that eliminates this need, and allows us to automatically write our generators in terms of Euler and orientation classes. This “factorization” algorithm works by forming a multiplication table for the $RO(G)$ homology, and then turns this table into a colored graph, somewhat analogous to the Cayley graph of a group. There are two colors, corresponding to multiplication and division, and traversing this graph is equivalent to generating expressions of the generators like those appearing in section 5.

This chains-based approach also works remarkably well with Massey products. And indeed, our program can compute Massey products, and their indeterminacy, directly from their definition. Finally, we can replace $\mathbb{Z}$ with any other constant Green functor corresponding to any user specified ring; a particularly interesting case is that of $\mathbb{F}_2$ coefficients.

All these details plus many more can be found in the documentation for our code available here.

The reader only interested in testing our program (in the case $G = C_4$) can simply download the executable for their operating system available here; no programming knowledge is required to run it.

The source code itself is written in C++ and hosted on a Github repository to encourage participation and contribution. We have tried to make the code
modular and extensible while at the same time fully documenting both how to use it and how it works under the hood.

3. The Mackey Functors

The data in a $C_4$-Mackey functor $M$ can be depicted using a Lewis diagram

$$
\begin{align*}
M(C_4/C_4) \\
\text{Res}_1^1 \uparrow \downarrow \text{Tr}_1^1 \\
M(C_4/C_2) \xrightarrow{C_4/C_2} \\
\text{Res}_2^1 \uparrow \downarrow \text{Tr}_2^1 \\
M(C_4/e) \xrightarrow{C_4}
\end{align*}
$$

We shall refer to $M(C_4/C_4)$ as the top level (or $C_4$ level), to $M(C_4/C_2)$ as the middle level (or $C_2$ level) and finally to $M(C_4/e)$ as the bottom level (or $e$ level).

To improve readability, we shall stop underlining our Mackey functors. The only potential point of confusion is $Z$ which could either denote the trivial $C_4$ module or the fixed point Mackey functor associated to it. Which one we mean will usually be clear from the context, but when the distinction is important we shall underline the Mackey functor $Z$.

We will also write $H^*(-)$ in place of $H^{C_4}(-; Z)$ and $H^{\star}(-)$ in place of $H^{C_4}(-; Z)$; the little and big asterisks stand for integer and RO$(C_4)$ grading respectively.

The real representation ring RO$(C_4)$ is generated by the irreducible representations $\sigma$ and $\lambda$ where $\sigma = \mathbb{R}$ is reflection and $\lambda = \mathbb{R}^2$ is rotation by $\pi/2$, both leaving $0$ fixed. So the computation of $H^{\star}(S)$ breaks down to calculating $H^{\star}(S^{n\sigma+m\lambda})$ for the four possible sign combinations. Here and throughout this paper, $n, m$ will always stand for nonnegative integers.

We now display the Lewis diagrams of the Mackey functors appearing in our computations.

For $H_\star S^{n\sigma+m\lambda}$ we have the 5 Mackey functors:

$$
\begin{align*}
\text{Z} & = \begin{pmatrix} Z \downarrow \downarrow 1 \{ \tilde{\sigma}, 1 \} \{ 2 \} \{ \} \{ \} \{ 2 \} \{ Z \} \xrightarrow{\text{-1}} \end{pmatrix} \\
\text{Z} & = \begin{pmatrix} Z \downarrow \downarrow 1 \{ \tilde{\sigma}, 1 \} \{ 2 \} \{ \} \{ \} \{ 2 \} \{ Z \} \xrightarrow{\text{-1}} \end{pmatrix} \\
\langle \text{Z} / 4 \rangle & = \begin{pmatrix} \text{Z} / 4 \downarrow \downarrow 1 \{ \tilde{\sigma}, 0 \} \{ 0 \} \{ \} \{ 0 \} \{ 0 \} \{ Z / 4 \} \xrightarrow{\text{-1}} \end{pmatrix} \\
\langle \text{Z} / 2 \rangle & = \begin{pmatrix} \text{Z} / 2 \downarrow \downarrow 0 \{ \tilde{\sigma}, 0 \} \{ \} \{ 0 \} \{ 0 \} \{ 0 \} \{ Z / 2 \} \xrightarrow{\text{-1}} \end{pmatrix} \\
\langle \text{Z} / 2 \rangle & = \begin{pmatrix} \text{Z} / 2 \downarrow \downarrow 0 \{ \tilde{\sigma}, 0 \} \{ \} \{ 0 \} \{ 0 \} \{ 0 \} \{ Z / 2 \} \xrightarrow{\text{-1}} \end{pmatrix}
\end{align*}
$$
For $H_*S^{m-n\sigma-m\lambda}$ we have the 4 additional Mackey functors:

\[
\begin{array}{cccc}
L = & Z & L_+ = & Z/2 \\
p^*L = & Z \left(1 \left\langle \begin{array}{c} \kappa \end{array} \right\rangle \right) & p^*L_+ = & Z \left(1 \left\langle \begin{array}{c} \kappa \end{array} \right\rangle \right) \downarrow -1
\end{array}
\]

Here $p^*$ denotes the functor from $C_2$ Mackey functors to $C_4$ Mackey functors induced by the quotient map $p : C_4 \to C_4/C_2$.

For $H_*S^{m\lambda-n\sigma}$ we also have the trivial extension $\langle Z/2 \rangle \oplus \langle Z/2 \rangle$ and the Mackey functor

\[
Q = \left\langle \begin{array}{c} \kappa \end{array} \right\rangle
\]

We have the nontrivial extensions

\[
0 \rightarrow \langle Z/2 \rangle \rightarrow Q \rightarrow \langle Z/2 \rangle \rightarrow 0
\]

\[
0 \rightarrow Q \rightarrow \langle Z/4 \rangle \rightarrow \langle Z/2 \rangle \rightarrow 0
\]

The additional Mackey functors present in $H_*S^{n\sigma-m\lambda}$ are the trivial extensions $Z_- \oplus \langle Z/2 \rangle$, $L \oplus \langle Z/2 \rangle$ and the 3 Mackey functors:

\[
\begin{array}{cccc}
L^2 = & Z \left(1 \left\langle \begin{array}{c} \kappa \end{array} \right\rangle \right) & Q^2 = & Z / 2 \left(1 \left\langle \begin{array}{c} \kappa \end{array} \right\rangle \right) \\
Z & Z \left(2 \left\langle \begin{array}{c} \kappa \end{array} \right\rangle \right) & Z / 2 & Z \left(2 \left\langle \begin{array}{c} \kappa \end{array} \right\rangle \right) \downarrow -1
\end{array}
\]

The sharp operation $\sharp$ exchanges $\text{Res}_1$ and $\text{Tr}_2$ in our Mackey functor, while the flat operation $\flat$ exchanges $\text{Res}_2$ and $\text{Tr}_1$. For example $p^*L = L^\flat$ and $p^*L_- = L_-^\flat$.

We have the nontrivial extensions

\[
0 \rightarrow \langle Z/2 \rangle \rightarrow \langle Z/4 \rangle \rightarrow Q^2 \rightarrow 0
\]

\[
0 \rightarrow \langle Z/2 \rangle \rightarrow Q^2 \rightarrow \langle Z/2 \rangle \rightarrow 0
\]

\[
0 \rightarrow L \rightarrow L^\flat \rightarrow \langle Z/2 \rangle \rightarrow 0
\]

\[
0 \rightarrow \langle Z/2 \rangle \rightarrow L_- \rightarrow Z^-_\flat \rightarrow 0
\]
4. The Generators

As a $C_4$-Mackey functor $M$ has three levels, a generator for $M$ consists of three elements $a, b, c$ that generate the abelian groups $M(C_4/C_4)$, $M(C_4/C_2)$ and $M(C_4/e)$ respectively. We shall employ the notation

$$a | b | c$$

to denote the top, middle and bottom generators in this order.

Now $\pi^\ast (HZ)$ is not just a (graded) Mackey functor, as it has a multiplicative structure making it a (graded) Green functor. Multiplication is performed levelwise and the Frobenius relation holds:

$$\text{Tr}^H_K (x \text{Res}^H_K y) = \text{Tr}^H_K (x) y$$

where $K \subseteq H$ are subgroups of $C_4$.

In this section we shall expound on the interplay between the Mackey functor and multiplicative structures, and demonstrate how every generator can be written in terms of the Euler and orientation classes. We begin by defining these classes in greater generality, following [HHR16].

For any real representation $V$ of a group $G$ we have the Euler class

$$a_V : S^0 \to S^V$$

given by the inclusion of the north and south poles $0, \infty$. We shall only consider the image of $a_V$ in homology but it’s important for some arguments to note that $a_V$ is defined on the sphere level.

If $V$ is orientable, namely the map $G \to GL(n)$ defining $V$ has positive determinant, then we have

$$H^G_n (S^V; \mathbb{Z}) = \mathbb{Z}$$

(cf [HHR16]). Choosing an orientation for $V$ determines an orientation class $u_V$ as the generator of the top level of this $\mathbb{Z}$. Without orienting $V$ there is a sign ambiguity for $u_V$.

In [HHR17] the following properties are proven in the case of $G = C_{2^n}$ (whenever $u_V$ appears it is implicit that $V$ is oriented).

- $a_V a_W = a_{V+W}$ and $u_V u_W = u_V u_W$
- $\text{Res}^G_H a_V = a_{\text{Res}^G_H V}$ and $\text{Res}^G_H u_V = u_{\text{Res}^G_H V}$
- $|G : \text{Stab}(V)| a_V = 0$ where $\text{Stab}(V)$ is the stabilizer (isotropy subgroup) of $V$.
- The Gold (au) Relation: If $V, W$ have dimension 2 and $\text{Stab}(V) \leq \text{Stab}(W)$,
  $$a_W u_V = |\text{Stab}(W) : \text{Stab}(V)| \cdot a_V u_W$$

In our case, the real $C_4$ representations are spanned by $1, \sigma, \lambda$ and the orientable ones are spanned by $1, 2\sigma, \lambda$. Therefore we have the classes

$$a_{\sigma}, a_{\lambda}, u_{2\sigma}, u_{\lambda}$$

living in the top level of $H^\ast S$. While $\sigma$ is not orientable as a $C_4$ representation, its restriction to $C_2 \subseteq C_4$ is the trivial $C_2$ representation so we can consider

$$u_{\sigma}$$

living in the middle level. We choose orientations coherently so that

$$\text{Res}_{2}^4(u_{2\sigma}) = u_{\sigma}^2$$
To simplify the notation, for an element \( a \) living in some level of a Mackey functor, we shall write \( \bar{a} \) for its restriction to the level directly below. If \( a \) lives in the top level, we can restrict \( \bar{a} \) again and then \( \bar{\bar{a}} \) will be the restriction two levels down. This notation is consistent with [HHR17].

The Euler and orientation classes generate the following Mackey functors:

\[
\begin{align*}
a_\sigma | 0 | 0 & \leadsto (\mathbb{Z} / 2) \\
\bar{a}_\lambda | \bar{a}_\lambda | 0 & \leadsto (\mathbb{Z} / 4) \\
u_{2\sigma} | u_2^2 | u_2^2 & \leadsto \mathbb{Z} \\
u_1 | \bar{\bar{a}}_\lambda | \bar{\bar{a}}_\lambda & \leadsto \mathbb{Z} \\
0 | u_{\sigma} | \bar{\bar{u}}_{\sigma} & \leadsto \mathbb{Z}_-
\end{align*}
\]

The Mackey functors themselves imply relations on these classes eg \( 2a_\sigma = 0 \). Moreover, since \( H_{\star}(S) \) is a Green functor we also have the Frobenius relation:

\[
\text{Tr}_K^H(x \text{ Res}_K^H y) = \text{Tr}_K^H(x) y
\]

We will refer to all these as secondary relations; the primary relations are those not implied by the additive (Mackey functor) structure or Frobenius. The only primary relation we have so far is the Gold relation:

\[
a_\sigma | u_{\lambda} = 2u_2 | a_\lambda
\]

The Euler and orientation classes generate multiplicatively all of \( H_*(S^{nm+ml}) \).

Before we explain how \( H_*(S^{-nm-ml}) \) is generated we need to take a moment and clarify what we mean by division:

### 4.1. A digression on divisibilities

Suppose we have elements \( x \in H_V S \) and \( y \in H_W S \) living on the same level. We will say that \( y/x \) exists if \( H_W - V S \) has a unique cyclic subgroup \( C \) such that multiplication by \( x \) maps \( C \subseteq H_W - V S \) isomorphically onto the cyclic subgroup \( \langle y \rangle \subseteq H_W S \) generated by \( y \):

\[
H_{W - V} S \xrightarrow{x} H_W S \xleftarrow{\uparrow} H_{W - V} S
\]

\[
C \xrightarrow{x \approx} \langle y \rangle
\]

The preimage of \( y \) under multiplication by \( x \) is a single element denoted by \( y/x \).

For example, \( 1/x \) exists iff \( x \) is invertible, and in that case \( 1/x = x^{-1} \) (and we will continue to use the \( x^{-1} \) notation for inverses).

However in general, \( y/x \) is less ambiguous than \( y^{-1}x \) as the latter notation might suggest that \( y^{-1} \) exists by itself and is multiplied with \( x \). For instance, \( 2/u_{2\sigma} \) exists because \( H_{-2}(S^{-2\sigma}) \xrightarrow{u_{2\sigma}} H_0(S) = \mathbb{Z} \) is an isomorphism onto \( 2 \mathbb{Z} \subseteq \mathbb{Z} \) in the top level. On the other hand, \( 1/u_{2\sigma} \) does not exist.

Getting back to \( H_*(S^{-nm-ml}) \), we will prove that \( u_{\sigma}^{-1} \) and \( \bar{\bar{u}}_{\lambda}^{-1} \) both exist. In fact, the following elements all exist:

\[
2/u_{2\sigma}, \quad 2/\bar{\bar{u}}_{\lambda}^m, \quad 4/u_{\lambda}^m, \quad 4/(u_{2\sigma}^m u_{\lambda}^m)
\]

Now for odd \( n \geq 3 \) set

\[
\omega_n = \text{Tr}_2^H(u_{\sigma}^{-n})
\]
We don’t consider \( w_1 \) because \( \text{Tr}_4(\bar{u}_\sigma^{-1}) = 0 \). Next for odd \( n \geq 1 \) and \( m \geq 1 \) set
\[
x_{n,m} = \text{Tr}_4^4(\bar{u}_\sigma^{-n}\bar{a}_\lambda^{-m})
\]
The \( w_n, x_{n,m} \) are all 2-torsion elements and we have the divisibilities:
\[
w_n/(a_{2\sigma}\bar{u}_\lambda^i), \quad x_{n,m}/a_{2\sigma}
\]
The first element not obtained by Euler and orientation classes through the operations of multiplication, division (wherever possible), transfers and restrictions is the generator \( s_3 \) in the top level of \( H_{-3}S^{-2\lambda} = (\mathbb{Z}/4) \). We have the divisibilities
\[
s_3/(u_{2\sigma}\bar{a}_\lambda^i u_\lambda^k), \quad \bar{s}_3/(u_{2\sigma}\bar{a}_\lambda^i\bar{u}_\lambda^k)
\]
Thus far we have accounted for every element in \( H_s(S^{m\lambda-n\sigma}) \) and \( H_s(S^{-\sigma-m\lambda}) \).

For \( H_s(S^{m\lambda-n\sigma}) \) we have additional elements
\[
u_\lambda/u_{2\sigma}, \quad (2a_\lambda)/(a_{2\sigma}u_{2\sigma})
\]
and for \( H_s(S^{-\sigma-m\lambda}) \) we have
\[
(2u_{2\sigma})/u_\lambda, \quad (4u_{2\sigma})/u_\lambda^i, \quad a_{2\sigma}^2/a_\lambda, \quad a_{2\sigma}^3/a_\lambda^m
\]
We also obtain the relations:
\[
2s_3 = w_3(a_{2\sigma}^3/a_\lambda^2)
\]
\[
a_{2\sigma}s_3 = \text{Tr}_2^4((2u_{2\sigma})/u_\lambda^2)
\]
In the second equation, multiplication by \( a_{2\sigma} \) is the projection \( \mathbb{Z}/4 \to \mathbb{Z}/2 \) so we equivalently have
\[
2s_3 = w_3(a_{2\sigma}^3/a_\lambda^2)
\]
\[
s_3 \mod 2 = \text{Tr}_2^4((2u_{2\sigma})/u_\lambda^2)/a_{2\sigma}
\]
expressing \( s_3 \) and \( s_3 \mod 2 \) in terms of Euler and orientation classes. Thus \( s_3 \) is obtained from Euler and orientation classes through the extension
\[
0 \to \mathbb{Z}/2 \to \mathbb{Z}/4 \to \mathbb{Z}/2 \to 0
\]
(note: the extension determines \( s_3 \) only up to a sign; i.e. \( s_3 \) cannot be canonically chosen from this extension). But if we want \( \text{Res}_2^4(s_3) \), then we need to replace this group extension with one of Mackey functors. In fact, in this case we have two such extensions:
\[
0 \to \langle \mathbb{Z}/2 \rangle \to L_- \to \mathbb{Z}^b_- \to 0
\]
\[
0 \to \overline{\langle \mathbb{Z}/2 \rangle} \to Q^b \to \langle \mathbb{Z}/2 \rangle \to 0
\]
- In the first extension, \( a_{2\sigma}s_3 \mid 0 \) generates \( \langle \mathbb{Z}/2 \rangle \) and \( 0 \mid (2u_{2\sigma})/u_\lambda^2|a_{2\sigma}\bar{u}_\lambda^{-2} \) generates \( \mathbb{Z}^b_- \).
- In the second extension, \( 0|u_{2\sigma}^3\bar{s}_3|0 \) generates \( \overline{\langle \mathbb{Z}/2 \rangle} \) and \( a_{2\sigma}^3/a_\lambda^2|0|0 \) generates \( \langle \mathbb{Z}/2 \rangle \).

From this description of the generators, we see that first short exact sequence gives the formula for \( a_{2\sigma}s_3 \) (which is equivalent to the formula for \( s_3 \mod 2 \)), while the second gives
\[
\bar{s}_3 = \text{Res}_2^4(a_{2\sigma}^3/a_\lambda^2)/u_{2\sigma}^3
\]
Applying \( \text{Tr}_2^4 \) on both sides returns the formula for \( 2s_3 \).
In order to summarize this whole discussion more concisely, we will use a more general notion of “generator”. In this notion, the span of a list of elements is not just polynomials on those generators combined with transfers and restrictions (the Green functor span) but we will also allow any divisibilities that occur as well as Mackey functor extensions in which the outer two Mackey functors are already in the span. For this to be well defined we need to note which divisibilities and extensions actually occur.

This generalized notion satisfies the following property: If we have two Green functor maps \( f, g : M \to N \) and \( M \) has a set \( A \) of generalized generators then \( f = g \) on \( M \) iff \( f = g \) on \( A \) and \( f = g \) on a generator for any extension that occurs (after all, these generators cannot be canonically chosen through the extensions).

The other part of this property has to do with whether or not a map \( f : A \to N \) extends to a Green functor map \( f : M \to N \). This is of course tantamount to \( f \) satisfying all Green functor relations. Ideally we would like to only list the primary relations on the generalized generators \( A \) and recover all other relations from these and the secondary ones (which result from the additive structure and the Frobenius relations). As we explain in subsection 4.2, this might not always be possible. In the special case of \( \pi^{C_{\ast}}(HZ) \) it does however work out so we can legitimately call them “primary relations”.

With this language, we can summarize this section as follows: The Green functor \( \pi^{C_{\ast}}(HZ) \) has generalized generators \( a_\sigma, u_{2\sigma}, u_\sigma, a_\lambda, u_\lambda \) in degrees \( \star = -\sigma, 2 - 2\sigma, 1 - \sigma, -\lambda, 2 - 2\lambda \) respectively. These classes individually generate the Mackey functors

\[
\begin{align*}
a_\sigma | 0 | 0 & \sim (\mathbb{Z}/2) \\
a_\lambda | a_\lambda | 0 & \sim (\mathbb{Z}/4) \\
u_{2\sigma} | u^2_{2\sigma} | \bar{u}^2_{2\sigma} & \sim \mathbb{Z} \\
u_\lambda | u_\lambda | a_\lambda & \sim \mathbb{Z} \\
0 | u_\sigma | a_\sigma & \sim \mathbb{Z}_-
\end{align*}
\]

and the only primary relation is the Gold relation

\[
a^2_{2\sigma} u_\lambda = 2u_{2\sigma} a_\lambda
\]

The only extension that occurs is for the generator \( s_3 | \bar{s}_3 | 0 \) of the \( \langle \mathbb{Z}/4 \rangle \) in dimension \( \star = -3 + 2\lambda \) and is specified by:

\[
\begin{align*}
\bar{s}_3 &= \text{Res}_2^4(a^3_{2\sigma}/a^3_\lambda) / u^3_{2\sigma} \\
a_\sigma \bar{s}_3 &= \text{Tr}_2^4((2u_\sigma)/a^3_\lambda)
\end{align*}
\]

There are many divisibilities that occur and we have indicated most of them earlier in this section; an exhaustive list is included in the next section together with the complete determination of the additive structure.

4.2. A technical remark. We end this section with a subtle point that can arise when combining multiplication and division. The problem is that the expressions \((x/z) \cdot (y/w)\) and \((xy)/(zw)\) are not always equivalent: one can exist when the other doesn’t, and even if both exist then they might not be equal! Case in point:

\[
w_3(a^3_{\sigma}/a^3_{\lambda}) \neq (w_3 a^3_{2\sigma}) / a^2_\lambda
\]
as the left hand side generates a $\mathbb{Z}/2$, while the right is trivial owing to $w_3a^3_{12} = 0$.

If $xz, y/w$ exist then $(x/z) \cdot (y/w) = (xy)/(zw)$ is equivalent to $(x/z) \cdot (y/w)$ and $xy$ generating isomorphic cyclic subgroups. In practice, the elements given by our spectral sequences are of the form $(x/z) \cdot (y/w)$ and the additive structure is known apriori, so we can readily check this equality.

For the generators displayed in section 5, the only instance where $(x/z) \cdot (y/w)$ and $(xy)/(zw)$ differ happens with

$$u^i_{2\sigma}(s^j/(a^k_{12}u^l_{12}))$$

for $i, j, k \geq 0$ and $i, k > 0$. This element generates a $\mathbb{Z}/4$ while $u^i_{2\sigma}s_3$ generates a $\mathbb{Z}/2$ and thus $(u^i_{2\sigma}s_3)/(a^k_{12}u^l_{12})$ does not equal the $\mathbb{Z}/4$ generator, but is rather the mod 2 reduction of that generator.

There’s another problem that stems from this point and it has to do with relations. We want to be able to reduce relations on $x/y$ to equivalent relations on $x$. A relation on $x/y$ takes the form $(x/y) \cdot z = 0 \in H_2S$ for some element $z \in H_\bullet S$.

If multiplication by $y$ is an isomorphism in $H_2S$ then we can clear denominators with $y$ and get the equivalent relation $xz = 0$. If it’s not an isomorphism then $xz = 0$ may not be equivalent to $(x/y) \cdot z = 0$.

Here’s an example arising in “nature”: Let’s take the generator

$$y = (w_3a_\lambda)/(a_\sigma u_{2\sigma})$$

of a $\mathbb{Z}/2$. We want to establish the relation $u_3y = 0$. First, the homology group $u_3y$ lives in is a $\mathbb{Z}/2$ (not 0), and neither $u_3$ nor $y$ are transfers (so we can’t use the Frobenius relation); this means that $u_3y = 0$ is not a secondary relation. Second, $u_3y = 0$ is not equivalent to $(u_3y)a_\sigma u_{2\sigma} = 0$ because multiplication by $a_\sigma u_{2\sigma}$ is not an isomorphism for the homology group $u_3y$ lives in.

However, the homology group $u_3y$ lives in is generated by $(w_3a_\lambda^2)/a_\sigma^3$, as we can see from the tables in section 5. So while multiplication by $a_\sigma u_{2\sigma}$ is not an isomorphism there, multiplication by $a_\sigma^3$ is. Thus $u_3y = 0$ is equivalent to $a_\sigma^2u_3y = 0$ which is true because $a_\sigma^2u_3 = 0$ by the Gold relation.

We employ a similar strategy when the homology group in the degree of the product is not cyclic. Let’s take for example the relation

$$(2u_{2\sigma}/u_\lambda)^2 = ((4u_{2\sigma}^2)/u_\lambda^2) + a_\sigma^4/a_\lambda^2$$

This “exotic multiplication” was pointed out to us by Mingcong Zeng. To prove it, write

$$(2u_{2\sigma}/u_\lambda)^2 = x \cdot (4u_{2\sigma}^2)/u_\lambda^2 + y \cdot a_\sigma^4/a_\lambda^2$$

for unknown integers $x, y$. To find $x$ we can multiply by $u_\lambda^2$ and use the relation

$$u_\lambda \cdot (a_\sigma^4/a_\lambda^2) = 0$$

proven in the Appendix (section 13). To find $y$ we instead multiply with $a_\lambda^2$ and use

$$a_\lambda \cdot (4u_{2\sigma}^2/u_\lambda^2) = 0$$

which is proven by appealing to Frobenius $((4u_{2\sigma}^2/u_\lambda^2) = Tr_{12}(4u_{2\sigma}^2/u_\lambda^2))$. In the end we get $x = y = 1$ as desired.
This strategy fails when we have generators that are not of the form $x/y$. For example the seemingly innocuous relation

$$s_3 \cdot (2u_{2e}/u_\lambda) = 2u_{2e}(s_3/u_\lambda)$$

can’t be proven by multiplying with $u_\lambda$ as the multiplication map can’t distinguish between 0 and $2u_{2e}(s_3/u_\lambda)$ due to $2s_3u_{2e} = 0$. It’s also not the image of another relation under multiplication by $u_{2e}$. Instead, we can immediately deduce the relation from the general simple fact of denominator exchange:

$$(x/z) \cdot (y/w) = (x/w) \cdot (y/z)$$

as long as $x/(zw), y/(zw)$ exist.

It turns out that for the integral $RO(C_4)$ homology of a point, all relations can be recovered from the Gold and the secondary relations using the ideas above. Proving this is quite tedious, as we need to consider all unordered pairs of generators that are not transfers and compute their product in terms of the other generators. This work is displayed in the Appendix (section 13).
5. The Results

We compile the results of our computation of the Green functor $H_* S^{\pm n\sigma \pm m\lambda} = H_*^G (S^{\pm n\sigma \pm m\lambda} ; \mathbb{Z})$ where $n, m \geq 0$ as always. We consider 8 separate cases based on the signs in $\pm n\sigma \pm m\lambda$ and the parity of $n$ (this parity determines whether the representation $\pm n\sigma \pm m\lambda$ is orientable or not); each case gets its own subsection containing both the additive and multiplicative structures. The 8 cases are ordered roughly in increasing complexity, which also happens to be the order in which we prove all these results in sections 7 through 12.

The notation for the Mackey functors and their generators has been explained in the preceding two sections. For improved formatting we shall write $\frac{1}{y}$ in place of $x/y$.

5.1. $H_* S^{n\sigma \pm m\lambda}$ for even $n$.

$$H_* (S^{n\sigma \pm m\lambda}) = \begin{cases} \mathbb{Z} & \text{if } * = n + 2m \\ \langle \mathbb{Z} / 4 \rangle & \text{if } n \leq * < n + 2m \text{ and } * \text{ is even} \\ \langle \mathbb{Z} / 2 \rangle & \text{if } 0 \leq * < n \text{ and } * \text{ is even} \end{cases}$$

- $u^{n/2}_c u^m_{\lambda} | u^n_{\lambda} \bar{u}^m_{\lambda}$ generates $H_{n+2m} = \mathbb{Z}$
- $u^{n/2}_c a^{m-i}_\lambda | u^n_{\lambda} a^m_{\lambda} | \bar{a}^i_{\lambda}$ generates $H_{n+2i} = \langle \mathbb{Z} / 4 \rangle$ for $0 \leq i < m$
- $a^{n-2i}_c u^i_{2c} a^m_{\lambda} | 0 | 0$ generates $H_{2i} = \langle \mathbb{Z} / 2 \rangle$ for $0 \leq i \leq \frac{n}{2} - 1$

5.2. $H_* S^{n\sigma \pm m\lambda}$ for odd $n$.

$$H_* (S^{n\sigma \pm m\lambda}) = \begin{cases} \mathbb{Z}_- & \text{if } * = n + 2m \\ \langle \mathbb{Z} / 2 \rangle & \text{if } n \leq * < n + 2m \text{ and } * \text{ is odd} \\ \langle \mathbb{Z} / 2 \rangle & \text{if } 0 \leq * < n + 2m \text{ and } * \text{ is even} \end{cases}$$

- $0 | u^n_{\epsilon} a^m_{\lambda} | u^n_{\epsilon} a^m_{\lambda}$ generates $H_{n+2m} = \mathbb{Z}_-$
- $0 | u^n_{\epsilon} a^{m-i}_\lambda | \bar{a}^i_{\lambda}$ generates $H_{n+2i} = \langle \mathbb{Z} / 2 \rangle$ for $0 \leq i < m$
- $a^{n-2i}_c u^i_{2c} a^m_{\lambda} | 0 | 0$ generates $H_{2i} = \langle \mathbb{Z} / 2 \rangle$ for $0 \leq i \leq \frac{n}{2} - 1$
- $a^{(n-1)/2}_c u^{m-i}_\lambda | u^i_{\lambda} | 0 | 0$ generates $H_{n+2i-1} = \langle \mathbb{Z} / 2 \rangle$ for $1 \leq i < m$
5.3. \( H_\ast S^{-n\sigma-m\lambda} \) for even \( n \). If \( n, m \) are not both 0,

\[
H_\ast(S^{-n\sigma-m\lambda}) = \begin{cases} 
L & \text{if } \ast = -n - 2m \quad \text{and } m \neq 0 \\
p^\ast L & \text{if } \ast = -n - 2m \quad \text{and } m = 0 \\
\langle \mathbb{Z}/4 \rangle & \text{if } -n - 2m < \ast < -n - 1 \quad \text{and } \ast \text{ is odd} \\
\langle \mathbb{Z}/2 \rangle & \text{if } -n - 1 \leq \ast < -1 \quad \text{and } \ast \text{ is odd and } m \neq 0 \\
\langle \mathbb{Z}/2 \rangle & \text{if } -n + 1 \leq \ast < -1 \quad \text{and } \ast \text{ is odd and } m = 0 
\end{cases}
\]

- \( \frac{4}{u_n^{n/2} u_m^m} \left| \frac{2}{u_n^{n/2} u_m^m} \right| \frac{1}{u_n^{n/2} u_m^m} \) generates \( H_{-n-2m} = L \) for \( m \neq 0 \)

- \( \frac{2}{u_n^{n/2}} \left| \frac{1}{u_n^{n/2}} \right| \frac{1}{u_n^{n/2}} \) generates \( H_{-n} = p^\ast L \) for \( m = 0 \)

- \( \frac{s_3}{u_n^{n/2} a_i^{i-2} u_m^{-i}} \left| \frac{s_3}{u_n^{n/2} a_i^{i-2} u_m^{-i}} \right| \) generates \( H_{-n-2m+2i-3} = \langle \mathbb{Z}/4 \rangle \) for \( 2 \leq i \leq m \)

- \( \frac{x_{2i+1,1}}{a_n^{n-2i-1} a_m^{-i-1}} \) generates \( H_{-2i-3} = \langle \mathbb{Z}/2 \rangle \) for \( 0 \leq i \leq \frac{m}{2} - 1, m \neq 0 \)

- \( \frac{w_{2i+3}}{a_n^{n-2i-3}} \) generates \( H_{-2i-3} = \langle \mathbb{Z}/2 \rangle \) for \( 0 \leq i < \frac{m}{2} - 1, m = 0 \)
5.4. $H, S^{-n\sigma-m\lambda}$ for odd $n$.

\[
H, (S^{-n\sigma-m\lambda}) = \begin{cases} 
L_- & \text{if } \ast = -n - 2m \text{ and } m \neq 0 \\
p^*L_- & \text{if } \ast = -n \text{ and } n > 1, m = 0 \\
Z_- & \text{if } \ast = -1 \text{ and } n = 1, m = 0 \\
\langle Z / 2 \rangle & \text{if } -n - 2m < \ast < -n - 1 \text{ and } \ast \text{ is even} \\
\langle Z / 2 \rangle & \text{if } -n - 2m < \ast < -1 \text{ and } \ast \text{ is odd}
\end{cases}
\]

- $x_{n,m} \left| \frac{2}{u^m n^m} \right| 1 \left| \frac{1}{\bar{u}^m a^m} \right|$ generates $H_{-n-2m} = L_-$ for $m \neq 0$
- $w_n | u^{-n}_{\sigma} | \bar{u}^{-n}_\sigma$ generates $H_{-n} = p^*L_-$ for $n > 1, m = 0$
- $0 | u^{-1}_{\sigma} | \bar{u}^{-1}_\sigma$ generates $H_{-1} = Z_-$ for $n = 1, m = 0$
- $0 | \frac{\bar{s}_3}{u^m n^m} | 0 | \frac{0}{\bar{u}^m a^m} \rangle$ generates $H_{-n-2m+2i-3} = \langle Z / 2 \rangle$ for $2 \leq i \leq m$
- $\frac{2s_3}{u^m n^m (n-1)/2} | 0 | 0 \rangle$ generates $H_{-n-2m+2i-2} = \langle Z / 2 \rangle$ for $2 \leq i \leq m$
- $\frac{X_{2i+1,1}}{u^m n^m} | 0 | 0 \rangle$ generates $H_{-2i-3} = \langle Z / 2 \rangle$ for $0 \leq i \leq \frac{n-1}{2}, m \neq 0$
- $\frac{w_{2i+3}}{u^m n^m} | 0 | 0 \rangle$ generates $H_{-2i-3} = \langle Z / 2 \rangle$ for $0 \leq i < \frac{n-3}{2}, m = 0$
5.5. $H_\ast S^{m\lambda - n\sigma}$ for even $n$. If $n, m$ are both nonzero,

$$H_\ast (S^{m\lambda - n\sigma}) = \begin{cases} 
\mathbb{Z} & \text{if } * = 2m - n \\
\langle \mathbb{Z} / 4 \rangle & \text{if } -n + 2 \leq * < 2m - n \hspace{1em} \text{and } * \text{ is even} \\
\langle \mathbb{Z} / 2 \rangle & \text{if } -n + 1 \leq * \leq -3 \hspace{1em} \text{and } * \text{ is odd} \\
Q & \text{if } * = -n
\end{cases}$$

- $\frac{u^m_\lambda}{u^{n/2}_\sigma} \frac{\bar{u}^m_\lambda}{u^{n/2}_\sigma}$ generates $H_{2m-n} = \mathbb{Z}$
- $\frac{\bar{a}^i_\lambda u^{m-i}_\lambda}{u^{n/2}_\sigma} \frac{\bar{a}^i_\lambda u^{m-i}_\lambda}{u^{n/2}_\sigma} 0$ generates $H_{2m-n-2i} = \langle \mathbb{Z} / 4 \rangle$ for $0 < i < m$
- $\frac{w^{2i+1}_\lambda a^m_\lambda}{a^{n-2i-1}_\sigma} 0 0$ generates $H_{-2i-1} = \langle \mathbb{Z} / 2 \rangle$ for $1 \leq i \leq \frac{n}{2} - 1$
- $\frac{2a^m_\lambda}{u^{n/2}_\sigma} \frac{\bar{a}^m_\lambda}{u^{n/2}_\sigma} 0$ generates $H_{-n} = Q$
5.6. $H_\ast S^{m\lambda-n\sigma}$ for odd $n$. If $m$ is nonzero,

\[
H_\ast(S^{m\lambda-n\sigma}) = \begin{cases} 
Z_\ast & \text{if } * = 2m-n \geq -1 \\
\langle Z/2 \rangle \oplus Z_\ast & \text{if } * = 2m-n \leq -3 \\
\langle Z/2 \rangle & \text{if } -1 \leq * < 2m-n \text{ and } * \text{ is odd} \\
\langle Z/2 \rangle & \text{if } 2m-n < * \leq -3 \text{ and } * \text{ is odd} \\
\langle Z/2 \rangle \oplus \langle Z/2 \rangle & \text{if } -n+2 \leq * < 2m-n \text{ and } * \text{ is odd and } * \leq -3 \\
\langle Z/2 \rangle & \text{if } -n+1 \leq * < 2m-n \text{ and } * \text{ is even} \\
Q & \text{if } * = -n \text{ and } n \geq 3 \\
\langle Z/2 \rangle & \text{if } * = -1 \text{ and } n = 1 \text{ and } m = 1
\end{cases}
\]

- $0 | u_r^{-n}\bar{a}_\lambda^m \bar{a}_r^{-n}\bar{a}_\lambda^m \rangle$ generates $H_{2m-n} = Z_\ast$

- $0 | \bar{a}_r^i \bar{a}_\lambda^{m-i} u_r^m \rangle$ generates the $\langle Z/2 \rangle$ in $H_{2m-n-2i}$ for $0 < i < m$

- $\frac{w_2i+1a_m}{a_{n-2i-1}} | 0 \rangle$ generates the $\langle Z/2 \rangle$ in $H_{-2i-1}$ for $1 \leq i \leq \frac{n-3}{2}$

- $\frac{2a_i^j u_r^{m-i}}{a_{n-1}/2} | 0 \rangle$ generates $H_{2m-n-2i+1} = \langle Z/2 \rangle$ for $1 \leq i \leq m$

- $w_n a_m | u_r^{-n} a_m^m \rangle$ generates $H_{-n} = Q$ for $n \geq 3$

- $0 | u_r^{-1}\bar{a}_\lambda^m \rangle$ generates $H_{-1} = \langle Z/2 \rangle$ for $n = m = 1$
5.7. \( H_s S^{n\sigma - m\lambda} \) for even \( n \). If \( n, m \) are both nonzero,

\[
H_s(S^{n\sigma - m\lambda}) = \begin{cases} 
Q^\sharp & \text{if } * = n - 3 \quad \text{and } m \geq 2 \\
\langle \mathbb{Z}/4 \rangle & \text{if } n - 2m < * < n - 3 \quad \text{and } * \text{ is odd} \\
\langle \mathbb{Z}/2 \rangle & \text{if } 0 \leq * \leq n - 4 \quad \text{and } * \text{ is even} \quad \text{and } * \neq n - 2m \\
L \oplus \langle \mathbb{Z}/2 \rangle & \text{if } * = n - 2m \quad \text{and } n - 2m \geq 0 \quad \text{and } m \geq 2 \\
L & \text{if } * = n - 2m \quad \text{and } n - 2m < 0 \quad \text{and } m \geq 2 \\
L^\sharp & \text{if } * = n - 2 \quad \text{and } m = 1 
\end{cases}
\]

- \( \frac{u_{2n/2}^n s_3}{a_{\lambda}^{m-2}} | \frac{u_{2n/2}^n \bar{s}_3}{a_{\lambda}^{m-2}} \rangle 0 \) generates \( H_{n-3} = Q^\sharp \) for \( m \geq 2 \)

- \( \frac{u_{2n/2}^{n-2i} u_{2n/2}^{i}}{a_{\lambda}^n} | 0 \rangle 0 \rangle \) generates \( H_{n-2m+2i-3} = \langle \mathbb{Z}/4 \rangle \) for \( 2 \leq i < m \)

- \( \frac{4u_{2n/2}^n}{u_{\lambda}^m} | 2u_{2n/2}^n \rangle | \bar{u}_{\lambda}^m \rangle \) generates the \( \langle \mathbb{Z}/2 \rangle \) in \( H_{2i} \) for \( 0 \leq i \leq \frac{m-4}{2} \)

- \( \frac{2u_{2n/2}^n}{u_{\lambda}} | 2u_{2n/2}^n \rangle | \bar{u}_{\lambda}^m \rangle \) generates the \( L \) in \( H_{n-2m} \) for \( m \geq 2 \)

- \( \frac{u_{2n/2}^n}{u_{\lambda}} | 2u_{2n/2}^n \rangle | \bar{u}_{\lambda}^m \rangle \) generates \( H_{n-2} = L^\sharp \) for \( m = 1 \)
5.8. $H_n S^{\sigma-m\lambda}$ for odd $n$. If $m$ is nonzero,

$$H_n (S^{\sigma-m\lambda}) = \begin{cases} 
Q^\dagger & \text{if } *=n-3 \quad \text{and } n \geq 3 \quad \text{and } m \geq 2 \\
\langle \mathbb{Z}/2 \rangle & \text{if } *=n-2 \quad \text{and } n = 1 \quad \text{and } m \geq 2 \\
\langle \mathbb{Z}/2 \rangle & \text{if } n-2m < * \leq n-4 \quad \text{and } * \text{ is odd} \\
\langle \mathbb{Z}/2 \rangle & \text{if } 0 \leq * < n-2m \quad \text{and } * \text{ is even} \\
\langle \mathbb{Z}/2 \rangle + \langle \mathbb{Z}/2 \rangle & \text{if } n-2m < * \leq n-5 \quad \text{and } * \text{ is even} \quad \text{and } 0 \leq * \\
\langle \mathbb{Z}/2 \rangle & \text{if } n-2m < * \leq n-5 \quad \text{and } * \text{ is even} \quad \text{and } * < 0 \\
L_- & \text{if } *=n-2m \quad \text{and } m \geq 2 \\
\langle \mathbb{Z}/2 \rangle & \text{if } 0 \leq * < n-2m \quad \text{and } * \text{ is even} \\
\langle \mathbb{Z}/2 \rangle \oplus \langle \mathbb{Z}/2 \rangle & \text{if } n-2m < * \leq n-5 \quad \text{and } * \text{ is even} \quad \text{and } * < 0 \\
\langle \mathbb{Z}/2 \rangle & \text{if } *=n-2 \quad \text{and } m = 1 
\end{cases}$$

- $\frac{a_v^3 u_{2_n}^{(n-3)/2}}{a_{m-2}^{m}} | 0 \rangle$ generates $H_{n-3} = Q^\dagger$ for $n \geq 3$ and $m \geq 2$

- $0 | \frac{u_v s_3}{\bar{a}_{m-2}} \rangle$ generates $H_{-2} = \langle \mathbb{Z}/2 \rangle$ for $n = 1$ and $m \geq 2$

- $\frac{a_v u_{2_n}^{(n-1)/2}}{a_{m-2}^{m-1} u_{m-1}^{m-1}} | 0 \rangle$ generates $H_{n-2m+2i-4} = \langle \mathbb{Z}/2 \rangle$ for $2 \leq i < m$

- $\frac{a_v^{m-2} u_{2_n}^{m}}{a_{m-2}^{m}} | 0 \rangle$ generates the $\langle \mathbb{Z}/2 \rangle$ in $H_{2i}$ for $0 \leq i < \frac{n-5}{2}$

- $0 | \frac{u_v s_3}{\bar{a}_{m-2}^{m-1} u_{m-1}^{m-1}} \rangle$ generates the $\langle \mathbb{Z}/2 \rangle$ in $H_{n-2m+2i-3}$ for $2 \leq i < m$

- $\frac{a_v u_{2_n}^{(n-1)/2}}{u_{m-2}^{m-2}} s_3 | 2 u_v^{m} \bar{u}_{m}^{m} \bar{u}_{m}^{m} \rangle$ generates $H_{n-2m} = L_-$ for $m \geq 2$

- $0 | \frac{2 u_v^{m} \bar{u}_{m}^{m} \bar{u}_{m}^{m}}{\bar{a}_{m}^{m}} \rangle$ generates $H_{n-2} = \mathbb{Z}_0^\dagger$ for $m = 1$
6. Computing the RO(G) graded homology

We explain the theoretical framework behind our computation of the RO(G) homology of a point for a finite group G. The results here are classical, but including them allows us to expound on the chain complexes and spectral sequences that we’ll be using in the following sections.

First, let us recall that the shift of a G-Mackey functor M at a finite G-set T is the Mackey functor MT specified on orbits as

\[ M_T(G/H) = M(T \times G/H) \]

Our goal is to compute

\[ H_*(S^V; M) \]

where \( V \) is a virtual representation of \( G \); in particular \( S^V \) is a spectrum, not a space (not even necessarily a suspension spectrum). For a general finite G-spectrum \( X \),

\[ H_*(X; M) \]

is computed using an equivariant cell decomposition of \( X \). This is a sequence of G-spectra \( X_p \) interpolating \( X_0 = S \) and \( X_n = X \) through cofiber sequences

\[ X_{p-1} \rightarrow X_p \rightarrow T_{p+} \wedge S^p \]

where the \( T_p \) are finite G-sets. Given such a decomposition, we have an Atiyah-Hirzebruch spectral sequence of Mackey functors

\[ E^1_{p,q} = H_q(T_{p+}, M) \Rightarrow H_{p+q}(X, M) \]

But by the definition of equivariant homology, \( H_q(T_{p+}, M) = MT_p \) concentrated in degree \( q = 0 \), hence the \( E_1 \) page is actually a chain complex with

\[ C_p(X; M) = MT_p \]

The boundary maps are induced from the geometric boundary maps

\[ T_{p+} \wedge S^p \rightarrow \Sigma X_{p-1} \rightarrow \Sigma (T_{(p-1)+} \wedge S^{p-1}) \]

in the following way: Smash the composite above with \( S^{-p} \) to get a G-map \( T_p \rightarrow T_{p-1} \) and then use the induced transfer map \( MT_p \rightarrow MT_{p-1} \) that is specified as:

\[ MT_p(G/H) = M(G/H \times T_p) \xrightarrow{Tr} M(G/H \times T_{p-1}) = MT_{p-1}(G/H) \]

This is the algebraic boundary map \( C_p \rightarrow C_{p-1} \).

The homology of the chain complex \( C_*(X; M) \) is \( H_*(X; M) \). We can do the same for cohomology and get the dual cochain complex \( C^*(X; M) \) (using the induced restriction maps \( C^p = MT_p \rightarrow C^{p+1} = MT_{p+1} \)).

So if we have an equivariant cell decomposition of \( X \) the problem of computing \( H_*(X; M) \) is reduced to algebra. If \( V \) is an actual (as opposed to virtual) representation, we might be able to find this decomposition of \( S^V \) from the geometry of the space, and that’s what we do in section 7. If \( V = -W \) where \( W \) is an actual representation then we can use Spanier-Whitehead duality and be reduced to the case already considered:

\[ H_*(S^V; M) = H^{-*}(S^W; M) \]
However, we can’t perform this trick if the virtual representation is \( V - W \). Instead, we use that \( S^{V-W} = S^V \wedge S^{-W} \) and smash the cell decompositions for \( S^V, S^W \) together to get one for \( S^{V-W} \). In general, given cell decompositions

\[
X_{n-1} \to X_n \to T_{n+1} \wedge S^n \\
Y_{n-1} \to Y_n \to T'_{n+1} \wedge S^n
\]

we get a cell decomposition of \( X \wedge Y \) by

\[
\text{ho colim}_{k+l=n} X_k \wedge Y_l \to \text{ho colim}_{k+l=n+1} X_k \wedge Y_l \to \left( \bigcup_{k+l=n+1} T_k \times T'_l \right)_+ \wedge S^{k+l}
\]

(this reduces to a fact in symmetric monoidal triangulated categories proven in [May01]). Therefore,

\[
C_*(X \wedge Y; M \boxtimes N) = (M \boxtimes N) \text{colim}_{k+l=\ast} T_k \times T'_l = \bigoplus_{k+l=\ast} (M \boxtimes N)_{T_k \times T'_l} = C_*(X; M) \boxtimes C_*(Y; N)
\]

The boundary maps match up as well.

In our case, we take \( M = N = Z \) and then \( H_*(S^{V-W}; Z) \) is computed as the homology of

\[
C_*(S^V; Z) \boxtimes C^{-\ast}(S^W; Z)
\]

Unfortunately, even if the \( C_* S^V \) and \( C^{-\ast} S^W \) are by themselves very small and easy to compute with (like in section 7), the box product can be extremely large very easily. So instead of a direct computation, we use algebraic spectral sequences converging to its homology.

In general, for any tensor product of chain complexes \( C \otimes D \) in a sufficiently good symmetric monoidal abelian category (like that of Mackey functors), we have three spectral sequences converging to \( H_*(C \otimes D) \). If we filter the double complex underlying the tensor product either horizontally or vertically, we get two spectral sequences with \( E_2 \) terms

\[
E_2 = H_*(C; H_* D) \implies H_*(C \otimes D) \\
E_2 = H_*(D; H_* C) \implies H_*(C \otimes D)
\]

Using Cartan-Eilenberg resolutions we obtain a Künneth spectral sequence

\[
E_2 = \text{Tor}^{\ast,\ast}(H_* C, H_* D) \implies H_*(C \otimes D)
\]

We refer the reader to [Wei94] and [Rot09] for details on their constructions but we shall not need them.

In our case of \( C_* (S^V) \boxtimes C^{-\ast} (S^W) \) the spectral sequences take the form

\[
E^p_{2,q} = H^p(S^V, H^{-q} S^W) \implies H_{p+q} S^{V-W} \\
E^p_{2,q} = H^p(S^W, H_{-q} S^V) \implies H_{p+q} S^{V-W} \\
E^p_{2,q} = \text{Tor}^{p,q}(H_p S^V, H_q S^{-W}) \implies H_{p+q} S^{V-W}
\]

These are all spectral sequences of \( Z \)-module and the final one uses the Tor in the symmetric monoidal category of \( Z \)-modules.

Finally, we remark that our three spectral sequences can also be obtained topologically. The first two are the Atiyah-Hirzebruch spectral sequences for the homology theory \( H_V \) and the final one is the topological Künneth spectral sequence.
7. Proofs Part I: \( H_*(S^{n_\sigma+m_\lambda}) \)

The results of this section also appear in \[HHR17\], but we have chosen to include them for the sake of completeness. As always, \( n, m \geq 0 \).

We can obtain equivariant cell decompositions for \( S^{n_\sigma+m_\lambda} \) as follows. View it as the compactification of the disc \( D(\mathbb{R}^n \times \mathbb{R}^{2m}) \) and include the \( C_4 \) subspace \( X_{n+2m-1} \) where either one of the final two coordinates is 0. The quotient space is

\[
S^{n_\sigma+m_\lambda} / X_{n+2m-1} = C_4^+ \wedge S^{n+2m}
\]

This is the wedge of four \( S^{n+2m} \)'s that correspond to the signs of the last two coordinates in \( D(\mathbb{R}^n \times \mathbb{R}^{2m}) \), and we use \((x_\pm, y_\pm)\) to represent them.

The space \( X_{n+2m-1} \) includes \( S^{n_\sigma+(m-1)_\lambda} \) as the \( C_4 \) subspace where both the last two coordinates are 0. The quotient is \( C_4^* \wedge S^{n+2m-1} \) and we use \((x_\pm, 0)\) and \((0, y_\pm)\) to represent the four spheres.

We continue like this until we reach \( S^{n_\sigma} \) and then we include \( S^{(n-1)_\sigma} \) (last coordinate 0) with quotient \((C_4/C_2)_+ \wedge S^n\); these are two spheres represented by \( x_+, x_- \). Eventually we will reach \( S^0 \) represented by "1".

We write \( \mathcal{Z}_{C_4}, \mathcal{Z}_{C_2} \) for the shifts of \( \mathcal{Z} \) at the orbits \( C_4/C_4 \) and \( C_4/C_2 \); these are also the fixed point Mackey functors of \( \mathcal{Z}[C_4], \mathcal{Z}[C_2] \) respectively.

In this notation, the chain complex for \( S^{n_\sigma+m_\lambda} \) is

\[
0 \to \mathcal{Z}_{C_4} \to \mathcal{Z}_{C_4} \to \cdots \to \mathcal{Z}_{C_4} \to \mathcal{Z}_{C_2} \to \mathcal{Z}_{C_2} \to \cdots \to \mathcal{Z}_{C_2} \to \mathcal{Z} \to 0
\]

The \( \mathcal{Z}_{C_2} \)'s are generated by \( x_\pm \) while the \( \mathcal{Z}_{C_4} \)'s are interchangeably generated by \((x_\pm, y_\pm)\) and \((x_\pm, 0), (0, y_\pm)\).

The differentials up to \( d_n \) are \( d_1 x_+ = 1, d_2 x_+ = x_+ - x_- \) and \( d_{2k+1} = x_+ + x_- \).

The differentials from \( d_{k+1} \) to \( d_{2m+n} \) depend on whether our sphere is \( C_4 \)-oriented or not. If \( n \) is even (oriented),

\[
d(x_+, y_+) = (x_+, 0) - (0, y_+)
\]

\[
d(x_+, 0) = 4 \sum (-1)^i g^i (x_+, y_+)
\]

If \( n \) is odd (non oriented),

\[
d(x_+, y_+) = (x_+, 0) + (0, y_+)
\]

\[
d(x_+, 0) = 4 \sum (-1)^i g^i (x_+, y_+)
\]

The differential \( d_{n+1} : \mathcal{Z}_{C_4} \to \mathcal{Z}_{C_2} \) is \( d(x_+, 0) = x_+ + x_- \) if \( n \) is even and \( d(x_+, 0) = x_+ - x_- \) if \( n \) is odd. Finally, if \( n = 0 \) the differential \( d_1 : \mathcal{Z}_{C_4} \to \mathcal{Z} \) is \( d_1 (x_+, 0) = 1 \).

These differentials can be computed geometrically, or inferred from the observation that the homology of the bottom level of \( C_4 S^{n_\sigma+m_\lambda} \) is the nonequivariant homology of \( S^{n_\sigma+m_\lambda} \) i.e. \( S^{n+2m} \), so the bottom level of \( C_4 S^{n_\sigma+m_\lambda} \) must be exact apart from the highest degree.

We readily compute the homology of \( C_+ S^{n_\sigma+m_\lambda} \) to be as follows:
If \( n \) is even,
\[
H_*(S^{n\sigma+m\lambda}) = \begin{cases} 
\mathbb{Z} & \text{if } * = n + 2m \\
\langle \mathbb{Z} / 4 \rangle & \text{if } n \leq * < n + 2m \text{ and } * \text{ is even} \\
\langle \mathbb{Z} / 2 \rangle & \text{if } 0 \leq * < n \text{ and } * \text{ is even}
\end{cases}
\]

If \( n \) is odd,
\[
H_*(S^{n\sigma+m\lambda}) = \begin{cases} 
\mathbb{Z} & \text{if } * = n + 2m \\
\langle \mathbb{Z} / 2 \rangle & \text{if } n \leq * < n + 2m \text{ and } * \text{ is odd} \\
\langle \mathbb{Z} / 2 \rangle & \text{if } 0 \leq * < n + 2m, * \text{ is even}
\end{cases}
\]

We now describe the multiplicative generators of \( H_*(S^{n\sigma+m\lambda}) \). Recall from section 4 that we have the Euler and orientation classes generating the Mackey functors:
\[
a_c|0|0 \in H_0(S^\sigma) = \langle \mathbb{Z} / 2 \rangle \\
a_\lambda|\bar{a}_\lambda|0 \in H_0(S^\lambda) = \langle \mathbb{Z} / 4 \rangle \\
u_{2c}|u_2^2|u_\sigma^2 \in H_2(S^{2\sigma}) = \mathbb{Z} \\
u_\lambda|\bar{u}_\lambda|\bar{a}_\lambda \in H_2(S^\lambda) = \mathbb{Z} \\
0|u_\sigma|\bar{u}_\sigma \in H_1(S^\sigma) = \mathbb{Z} -
\]
and satisfying the Gold Relation:
\[
a_c^2u_\lambda = 2a_\lambda u_{2c}
\]

These classes multiplicatively generate all of \( H_*(S^{n\sigma+m\lambda}) \) and the only primary relation is the Gold. This claim follows easily from the following observations: Multiplication by \( a_c : S^0 \to S^\sigma \) induces the chain map
\[
C_*S^{n\sigma+m\lambda} \to C_*S^{(n+1)\sigma+m\lambda}
\]
that is \( Z_{C_2} \overset{1}{\to} Z_{C_2} \) for \( * \leq n \), \( Z_{C_4} \overset{1}{\to} Z_{C_4} \) for \( n + 1 \leq * \leq n + 2m \) and the map \( Z_{C_4} \to Z_{C_2} \) given by the canonical projection \( Z[C_4] \to Z[C_4/C_2] \) at bottom level. For \( m = 0 \), \( a_\sigma \) is the canonical inclusion \( C_*S^{n\sigma} \to C_*S^{(n+1)\sigma} \). Similarly, multiplication by \( a_\lambda \) induces the canonical inclusion \( C_*S^{n\sigma+m\lambda} \to C_*S^{(n+1)\sigma+m\lambda} \).

From these observations it follows that multiplication by \( a_c, a_\lambda \) is an isomorphism in certain dimensions which is enough to prove the multiplicative generation of \( H_*(S^{n\sigma+m\lambda}) \) by Euler and orientation classes.

8. Proofs Part II: \( H_*(S^{-n\sigma-m\lambda}) \)

To get \( H_*(S^{-n\sigma-m\lambda}) \) we use Spanier-Whitehead Duality:
\[
H_*(S^{-n\sigma-m\lambda}) = H^{-*}(S^{n\sigma+m\lambda})
\]
and cohomology is computed by the dual chain complex \( C^*(S^{n\sigma+m\lambda}) \). The results:

If \( n \) is even,
generating the top level of \( H^* \) isomorphism in top level.

compute these transfers through the Frobenius relations; for example,

\[x^* \rightarrow w^* \rightarrow w^* \rightarrow 4/ Z_+\]

We have:

\[L_- \quad \text{if } * = -n - 2m < -1 \text{ and } m \neq 0\]
\[p^* L_- \quad \text{if } * = -n - 2m = 0\]
\[\langle Z / 2 \rangle \quad \text{if } * = -n - 1 \leq m < -n \text{ and } * \text{ odd and } m \neq 0\]
\[\langle Z / 2 \rangle \quad \text{if } * = -n + 1 \leq m < -n \text{ and } * \text{ odd and } m = 0\]

If \( n \) is odd,

\[H_+(S^{-n* - m\lambda}) = \begin{cases} L_- & \text{if } * = -n - 2m < -1 \text{ and } m \neq 0 \\ p^* L_- & \text{if } * = -n - 2m = 0 \\ \langle Z / 2 \rangle & \text{if } * = -n - 1 \leq m < -n \text{ and } * \text{ odd and } m \neq 0 \\ \langle Z / 2 \rangle & \text{if } * = -n + 1 \leq m < -n \text{ and } * \text{ odd and } m = 0 \\ \end{cases}\]

We shall now find the multiplicative generators of \( H_+(S^{-n* - m\lambda}) \).

First note that \( u_{\sigma} \in H_2S^\lambda = Z\{x_+ - x_-\} \) pairs with the generator of \( H_2S^{-\lambda} = Z^{-\{x_+ \}} \) to \( x_+ (x_+ - x_-) = 1 \) hence it’s invertible. Similarly \( u_{\lambda} \) is invertible.

The transfers on the products of \( u_{\sigma}^{-1}, u_{\lambda}^{-1} \) generate the \( L, L_- \)’s since these elements do so on the bottom level (and transfers are surjective for \( L, L_- \)). We can compute these transfers through the Frobenius relations; for example,

\[\text{Tr}^4(u_{\sigma}^{-2n} u_{\lambda}^{-m}) = 4/(u_{2\sigma} u_{\lambda}^m)\]

We have:

- \( 4/(u_{2\sigma} u_{\lambda}^m)2/(u_{\sigma} u_{\lambda}^m) \) \( u_{\sigma}^{-2n} u_{\lambda}^{-m} \) generates \( L \) for \( m > 0 \)
- \( 2/ u_{2\sigma} u_{\lambda}^{2n} u_{\sigma}^{-2n} \) generates \( p^* L_- \)

For odd \( n \geq 3 \) let

\[w_n = \text{Tr}^4(u_{\sigma}^{-n}) = w_5/n_{2\sigma}^{(n-3)/2}\]

generating the top level of \( H_{-n}S^{-n*} = p^* L_- \). For \( n = 1 \) this transfer is 0 so we don’t define a \( w_1 \). Next, for odd \( n \geq 1 \) and any \( m \geq 1 \) let

\[x_{n,m} = \text{Tr}^4(u_{\sigma}^{-n} u_{\lambda}^{-m}) = x_{1,1}/(u_{2\sigma}^{(n-1)/2} u_{\lambda}^{m-1})\]

generating the top level of \( H_{-n-2m}S^{-n*+m\lambda} = L_- \). We have

- \( x_{n,m}2/(u_{\sigma} u_{\lambda}^m) u_{\sigma}^{-n} u_{\lambda}^{-m} \) generates \( L_- \)
- \( w_n u_{\sigma}^{-n} u_{\lambda}^{-m} \) generates \( p^* L_- \)

The \( w_n \) are infinitely divisible by \( a_{\sigma} \) since \( a_{\sigma} : S^{n*} \rightarrow S^{(n+1)*} \) is the inclusion in chains \( C_* S^{n*} \rightarrow C_* S^{(n+1)*} \) hence projection in cochains \( C^* S^{n*} \rightarrow C^* S^{(n+1)*} \) which is a quasi-isomorphism in top level for odd \( n \).

- \( w_n/a_{\sigma}^4 \) generates \( \langle Z / 2 \rangle \)

The \( w_n/a_{\sigma}^4 \) are infinitely divisible by \( a_{\lambda} \) since \( a_{\lambda} : S^{n*+m\lambda} \rightarrow S^{n*+(m+1)\lambda} \) gives the projection of cochain complexes \( C^* S^{n*+(m+1)\lambda} \rightarrow C^* S^{n*+m\lambda} \) which is a quasi-isomorphism in top level.

Now note that the \( x_{n,m} \) are also infinitely \( a_{\sigma} \) divisible. This is because

\[a_{\sigma} : C^* S^{(n+1)*+m\lambda} \rightarrow C^* S^{n*+m\lambda}\]
is identity for \(* \leq n\) or \(n + 2 \leq * \leq n + 2m\), while for \(* = n + 1\) it’s the map 
\(\mathbb{Z}C_1 \to \mathbb{Z}C_2\) dual to \(\mathbb{Z}[C_4] \to \mathbb{Z}[C_4/C_2]\). This is an isomorphism in top level.

The \(w_n/(a_n^i a_\lambda^j)\) and \(x_{n,m}/a_\sigma^i\) generate the top levels of \(\langle \mathbb{Z}/2 \rangle\)'s, so if they occur at the same dimensions they must be equal. Thus

\[x_{1,1}/a_\sigma^2 = w_3/a_\lambda\]

and in general,

\[x_{n,m}/a_\sigma^i = x_{n,1}/(a_\sigma^i u_\lambda^{m-1}) = w_{n+2}/(a_\sigma^{i-2} a_\lambda u_\lambda^{m-1})\]

for odd \(n\) and \(m \geq 1\) and \(i \geq 2\).

So the \(x_{n,1}/a_\sigma^i\) are infinitely divisible for \(i \geq 2\) and odd \(n\).

- \(x_{2i+1,1}/(a_\sigma^{2} a_\lambda^{m-2} u_\lambda^{m-1})\) generates \(\langle \mathbb{Z}/2 \rangle\).

Let \(s_3 \in H_3(S^{-2\lambda}) = \langle \mathbb{Z}/4 \rangle\) be the generator (unique up to a sign). It is infinitely divisible by \(u_\lambda\): Indeed, we have the commutative diagram

\[\begin{array}{ccc}
H_{-3-2i}(C_4/C_4) &=& \mathbb{Z}/4 \\
\downarrow & & \downarrow \\
H_{-3-2i}(C_4/C_2) &=& \mathbb{Z}/2
\end{array}\]

where the right column is generated by \(s_3, \bar{s}_3\) and the bottom horizontal map is an isomorphism by \(\tilde{n}_G^C(H\mathbb{Z})\) computation in [HHR17] (because \(C_2\) only has one nontrivial irreducible real representation this computation is significantly shorter and easier than the \(C_4\) case, but we will not reproduce it here).

The element \(s_3/u_\lambda^i\) is infinitely divisible (by either the \(C_2\) restriction argument or the usual inclusion of chains argument) and \(s_3/(a_\lambda^i u_\lambda^i)\) generates the top level of \(\langle \mathbb{Z}/4 \rangle\). To get the remaining \(\langle \mathbb{Z}/4 \rangle\) which appear as in the homology \(S^{-n\sigma-m\lambda}\) for even \(n\) we can further multiply by \(u_\sigma^{-n}\) in the middle level, which gives \(s_3/(u_\sigma^{2}\bar{a}_\lambda^i u_\lambda^i)\) as the top level generator. We conclude:

- \(s_3/(u_\sigma^{2}\bar{a}_\lambda^i u_\lambda^i)\) \(\bar{s}_3/(u_\lambda^j a_\lambda^j)\) \(0\) generates \(\langle \mathbb{Z}/4 \rangle\) for \(i, j \geq 0\) and even \(n\).
- \(0\bar{s}_3/(u_\lambda^j a_\lambda^j)\) \(0\) generates \(\langle \mathbb{Z}/2 \rangle\) for \(i, j \geq 0\) and odd \(n\).

9. Proofs Part III: Preparation for \(H_+ (S^{m\lambda-n\sigma})\)

In this section and the next we will compute \(H_+ (S^{m\lambda-n\sigma})\) for \(m, n \geq 1\).

Recall from section 6 that there are three algebraic spectral sequences we can use for this computation. This section is devoted to determining the Mackey functors in their \(E_2\) pages; we will figure out the differentials and extensions in the next section.

We omit the multiplicative presentation of certain generators in the \(E_2\) page of some of our spectral sequences. These generators either don’t survive the spectral sequence, or if they do then we can figure out their multiplicative presentation in the \(E_\infty\) page by comparison with the other spectral sequences.

9.1. The Homological Spectral Sequence. The HSS is

\[E_{p,q}^2 = H_p(S^{m\lambda}, H_q S^{-n\sigma}) \implies H_{p+q}(S^{m\lambda-n\sigma})\]
We compute the $E_2$ page (sans differentials) directly with the chain complex

$$C_*(S^{m\lambda}; H_q S^{-nc}) = C_*(S^{m\lambda}) \otimes H_q(S^{-nc})$$

and get the following results. First,

$$H_*(S^{m\lambda}; H_{-1} S^{-\sigma}) = H_*(S^{m\lambda}; Z_-) = \begin{cases} \mathbb{Z} & \text{if } * = 2m \\ \langle \mathbb{Z} / 2 \rangle & \text{if } 0 \leq * \leq 2m - 2 \text{ and } * \text{ is even} \\ \langle \mathbb{Z} / 2 \rangle & \text{if } 1 \leq * \leq 2m - 1 \text{ and } * \text{ is odd} \end{cases}$$

The multiplicative generators:

- $0|u_{-1}^{-1} \tilde{a}_\lambda^m|u_{-1}^{-1} \tilde{a}_\lambda^m$ generates $\mathbb{Z}_-$
- $0|u_{-1}^{-1} \tilde{a}_\lambda^i|u_{-1}^{-1} \tilde{a}_\lambda^i|0$ generates $\langle \mathbb{Z} / 2 \rangle$ for $0 < i \leq m$

Second, for even $n \geq 2$,

$$H_*(S^{m\lambda}; H_{-n} S^{-nc}) = H_*(S^{m\lambda}; p^* L) = \begin{cases} \mathbb{Z} & \text{if } * = 2m \\ \langle \mathbb{Z} / 4 \rangle & \text{if } 2 \leq * < 2m \text{ and } * \text{ is even} \\ \{0\} & \text{if } * = 0 \end{cases}$$

The multiplicative generators:

- $u_\lambda^m / u_{2\sigma}^{n/2} |u_{-n} \tilde{a}_\lambda^m|u_{-n} \tilde{a}_\lambda^m$ generates $\mathbb{Z}$
- $(a^i_\lambda u_{-n}^{-i}|u_{2\sigma}^{n/2} |u_{-n} \tilde{a}_\lambda^i|u_{-n} \tilde{a}_\lambda^i|0$ generates $\langle \mathbb{Z} / 4 \rangle$ for $0 < i < m$
- $(2a^m_\lambda) / u_{2\sigma}^{n/2} |u_{-n} \tilde{a}_\lambda^m|0$ generates $\mathbb{Q}$.

Third, for odd $n \geq 3$,

$$H_*(S^{m\lambda}; H_{-n} S^{-nc}) = H_*(S^{m\lambda}; p^* L_-) = \begin{cases} \mathbb{Z}_- & \text{if } * = 2m \\ \langle \mathbb{Z} / 2 \rangle & \text{if } 1 \leq * \leq 2m - 1 \text{ and } * \text{ is odd} \\ \langle \mathbb{Z} / 2 \rangle & \text{if } 2 \leq * \leq 2m - 2 \text{ and } * \text{ is even} \\ \{0\} & \text{if } * = 0 \end{cases}$$

The multiplicative generators:

- $0|u_{-n} \tilde{a}_\lambda^m|u_{-n} \tilde{a}_\lambda^m$ generates $\mathbb{Z}_-$
- $0|u_{-n} \tilde{a}_\lambda^i|u_{-n} \tilde{a}_\lambda^i|0$ generates $\langle \mathbb{Z} / 2 \rangle$ for $0 < i < m$
- $w_{n}a^m_\lambda|u_{-n} \tilde{a}_\lambda^m|0$ generates $\mathbb{Q}$.

Finally,

$$H_*(S^{m\lambda}; H_{-2i-1} S^{-nc}) = H_*(S^{m\lambda}; \langle \mathbb{Z} / 2 \rangle) = \langle \mathbb{Z} / 2 \rangle$$

consentrated in degree $* = 0$ and generated by $(w_{2i+1}a^m_\lambda)/a_{\xi}^{n-2i+1}$ for $1 \leq i < (n - 1)/2$. 

26
9.2. The Cohomological Spectral Sequence. The CSS is
\[ E_2^{p,q} = H_p(S^{-n\sigma}; H_{q-2m\lambda}) \implies H_{p+q}(S^{m\lambda-n\sigma}) \]

The Mackey functors in the \( E_2 \) page are computed in a similar fashion as the HSS, and are as follows: First, \( H_{-\ast}(S^{-n\sigma}; H_{2m\lambda}) = H_{-\ast}(S^{-n\sigma}; \mathbb{Z}) \) was computed in the previous section. Next,

\[ H_{-\ast}(S^{-n\sigma}; H_{2m\lambda}) = H_{-\ast}(S^{-n\sigma}; \langle \mathbb{Z}/4 \rangle) = \begin{cases} \mathbb{Q} & \text{if } \ast = n \geq 2 \\ \langle \mathbb{Z}/2 \rangle & \text{if } 0 \leq \ast < n \text{ and } \ast \neq 1 \\ \langle \mathbb{Z}/2 \rangle & \text{if } \ast = n = 1 \end{cases} \]

for even \( i \) is even and \( 0 \leq i \leq 2m \). The multiplicative generators:
- \( (2a_{\lambda}^{m-i}u_{\lambda}^i)/u_{\sigma}^{n/2}|u_{\sigma}^{-n}a_{\lambda}^{m-i}a_{\lambda}^i|0 \) generates \( \mathbb{Q} \) for even \( n \geq 2 \).
- \( w_{n}a_{\lambda}^{m-i}u_{\lambda}^i|u_{\sigma}^{-n}a_{\lambda}^{m-i}a_{\lambda}^i|0 \) generates \( \mathbb{Q} \) for odd \( n \geq 3 \).
- \( (w_{2j+1}a_{\lambda}^{m-i}u_{\lambda}^i)/a_{\sigma}^{n-2^j-1}|0|0 \) generates \( \langle \mathbb{Z}/2 \rangle \) in odd degrees.
- \( (2a_{\lambda}^{m-i}u_{\lambda}^i)/a_{\sigma}^{n}|0|0 \) generates \( \langle \mathbb{Z}/2 \rangle \) at degree 0.
- \( 0|u_{\sigma}^{-1}a_{\lambda}^{m-i}a_{\lambda}^i|0 \) generates \( \langle \mathbb{Z}/2 \rangle \).

9.3. The Kunneth Spectral Sequence. The KSS is
\[ E_2^{p,q} = \text{Tor}_{\mathbb{Z}}^{p+1}(H_*S^{m\lambda-(n-1)\sigma}, \mathbb{Z}_- \implies H_{p+q}(S^{m\lambda-n\sigma}) \]

This is the Kunneth spectral sequence for \( S^{m\lambda-(n-1)\sigma} \wedge S^{-\sigma} \) and we have used that \( H_*S^{-\sigma} = \mathbb{Z}_- \) concentrated in degree \( \ast = -1 \). A free resolution of \( \mathbb{Z}_- \) is

\[ 0 \to \mathbb{Z} \xrightarrow{\Delta} \mathbb{Z}_2 \xrightarrow{\nabla} \mathbb{Z}_- \to 0 \]

We list only the nonzero Tor’s below, dropping the subscript \( \mathbb{Z} \) from the notation:
- \( \text{Tor}^0((\mathbb{Z}/4), \mathbb{Z}_-) = \langle \mathbb{Z}/2 \rangle \) and \( \text{Tor}^1((\mathbb{Z}/4), \mathbb{Z}_-) = \langle \mathbb{Z}/2 \rangle \)
- \( \text{Tor}^0((\mathbb{Z}/2), \mathbb{Z}_-) = \mathbb{Q} \)
- \( \text{Tor}^0(Q, \mathbb{Z}_-) = Q \) and \( \text{Tor}^1(Q, \mathbb{Z}_-) = \langle \mathbb{Z}/2 \rangle \)
- \( \text{Tor}^1((\mathbb{Z}/2), \mathbb{Z}_-) = \langle \mathbb{Z}/2 \rangle \)
- \( \text{Tor}^0(\mathbb{Z}_-, \mathbb{Z}_-) = p^*L \)
- \( \text{Tor}^0(p^*L, \mathbb{Z}_-) = p^*L_- \)
- \( \text{Tor}^0(p^*L_-, \mathbb{Z}_-) = p^*L_- \) and \( \text{Tor}^1(p^*L_-, \mathbb{Z}_-) = \langle \mathbb{Z}/2 \rangle \)
- \( \text{Tor}^0(L, \mathbb{Z}_-) = L_- \)
- \( \text{Tor}^0(L_-, \mathbb{Z}_-) = L_+ \) and \( \text{Tor}^1(L_-, \mathbb{Z}_-) = \langle \mathbb{Z}/2 \rangle \)

Note that \( \text{Tor}^*(\mathbb{Z}_-, -) \) vanishes above \( \ast = 1 \) by the resolution of \( \mathbb{Z}_- \). This means that the KSS is concentrated in the first two columns, hence always collapses for dimensional reasons. That said, we still need the HSS to solve the extension problems in the KSS and get the multiplicative generators. We only make a single use of the CSS and that’s for \( n = 1 \).
10. PROOFS PART IV: $H_*(S^{m\lambda-n\sigma})$

We first compute $H_*(S^{m\lambda-n\sigma})$ separately for $n = 1$ through $n = 5$ using the spectral sequences explained in the preceding section. The KSS used to compute $S^{m\lambda-n\sigma}$ works by feeding it the answer of the computation for $n-1$, so we perform our calculations in order of increasing $n$. The general $n$ case follows by induction, exhibiting very similar behavior to the $n = 4$ and $n = 5$ cases, depending on the parity of $n$.

10.1. **The case $n = 1$.** The CSS for $S^{m\lambda-\sigma}$ is concentrated in the first two rows and even columns, hence collapses with no extensions to

$$H_*(S^{m\lambda-\sigma}) = \begin{cases} \mathbb{Z} & \text{if } * = 2m-1 \\ \langle \mathbb{Z}/2 \rangle & \text{if } -1 \leq * < 2m-3 \text{ and } * \text{ is odd} \\ \langle \mathbb{Z}/2 \rangle & \text{if } 0 \leq * < 2m-2 \text{ and } * \text{ is even} \end{cases}$$

The multiplicative generators are also obtained immediately from the CSS and are as follows:

- $0|u_{-1}^{-1}\bar{u}_{\lambda}^m|a_{-1}^{-1}\bar{u}_{\lambda}^m$ generates $\mathbb{Z}$. 
- $0|u_{-1}^{-1}\bar{a}_{\lambda}^i\bar{a}_{\lambda}^m-i|0$ generates $\langle \mathbb{Z}/2 \rangle$ for $0 < i \leq m$
- $(2a_{\lambda}^i u_{-1}^{m-i})/a_{-1}|0|0$ generates $\langle \mathbb{Z}/2 \rangle$ for $0 < i \leq m$

10.2. **The case $n = 2$.** The HSS for $S^{m\lambda-2\sigma}$ similarly collapses with no extensions to give:

$$H_*(S^{m\lambda-2\sigma}) = \begin{cases} \mathbb{Z} & \text{if } * = 2m-2 \\ \langle \mathbb{Z}/4 \rangle & \text{if } 0 \leq * < 2m-2 \text{ and } * \text{ is even} \\ Q & \text{if } * = -2 \end{cases}$$

The multiplicative generators:

- $u_{\lambda}^m/u_{2\sigma}|u_{-1}^{2}\bar{u}_{\lambda}^m|a_{-1}^{2}\bar{u}_{\lambda}^m$ generates $\mathbb{Z}$.
- $(a_{\lambda}^i u_{-1}^{m-i})/u_{-1}^{2}\bar{a}_{\lambda}^i\bar{a}_{\lambda}^m-i|0$ generates $\langle \mathbb{Z}/4 \rangle$ for $0 < i < m$.
- $(2a_{\lambda}^{m})/u_{-1}^{2}\bar{a}_{\lambda}^m u_{-1}^0|0$ generates $Q$.

10.3. **The case $n = 3$.** The KSS for $S^{m\lambda-3\sigma} \land S^{-\sigma}$ collapses with no extensions to give:

$$H_*(S^{m\lambda-3\sigma}) = \begin{cases} \mathbb{Z} & \text{if } * = 2m-3 \\ \langle \mathbb{Z}/2 \rangle & \text{if } -2 \leq * < 2m-3 \text{ and } * \text{ is even} \\ \langle \mathbb{Z}/2 \rangle & \text{if } -1 \leq * < 2m-3 \text{ and } * \text{ is odd} \\ Q & \text{if } * = -3 \end{cases}$$

The multiplicative generators:

- $0|u_{-1}^{-3}\bar{u}_{\lambda}^m|a_{-1}^{-3}\bar{u}_{\lambda}^m$ generates $\mathbb{Z}$. 
- $(2a_{\lambda}^i u_{-1}^{m-i})/(a_{-1} u_{-1}^{2\sigma})|0|0$ generates $\langle \mathbb{Z}/2 \rangle$ for $0 < i \leq m$.
- $0|u_{-1}^{-3}\bar{a}_{\lambda}^i\bar{a}_{\lambda}^m-i|0$ generates $\langle \mathbb{Z}/2 \rangle$ for $0 < i < m$
- $w_{-3} a_{\lambda}^m u_{-1}^{-3}\bar{a}_{\lambda}^m|0$ generates $Q$.

The generator of $\langle \mathbb{Z}/2 \rangle$ is not immediately obtained from the three spectral sequences. Instead, our argument uses the result of the next subsection for $H_*(S^{m\lambda-4\sigma})$, the computation of which does not use the expression for the $\langle \mathbb{Z}/2 \rangle$
generator so our reasoning is not circular. Given the computation of \( H_*(\mathcal{S}^{m\lambda-4\sigma}) \) we have on top level:

\[
\begin{array}{c}
H_{2m-4}(\mathcal{S}^{m\lambda-4\sigma}) \\
\downarrow \overset{a_\sigma}{\longrightarrow}
\end{array}
\begin{array}{c}
H_{2m-4}(\mathcal{S}^{m\lambda-2\sigma}) \\
\downarrow \overset{a_\sigma}{\longrightarrow}
\end{array}
\begin{array}{c}
\mathbb{Z} u^m_m/u^2_{2\sigma} \\
\overset{a_\sigma}{\longrightarrow}
\mathbb{Z}/2 \\
\overset{a_\sigma}{\longrightarrow}
\mathbb{Z}/4(a_{\lambda}u_{\lambda}^{m-1})/u_{2\sigma}
\end{array}
\]

The composite \( a_\sigma^2 \) sends the generator in \( \mathbb{Z} \) to twice the generator in \( \mathbb{Z}/4 \) by the Gold Relation, hence the second map \( a_\sigma \) must be the canonical inclusion \( \mathbb{Z}/2 \to \mathbb{Z}/4 \); we conclude that the middle generator is \((2a_{\lambda}u_{\lambda}^{m-1})/(a_{\sigma}u_{2\sigma})\).

Similarly, we can prove that the other \langle \mathbb{Z}/2 \rangle\)'s in \( H_*(\mathcal{S}^{m\lambda-3\sigma}) \) are generated by \((2a_{\lambda}u_{\lambda}^{m-1})/(a_{\sigma}u_{2\sigma})\) (but now in the argument above use \( \mathbb{Z}/4 \) in the place of \( \mathbb{Z} \)).

10.4. The case \( n = 4 \). For \( \mathcal{S}^{m\lambda-4\sigma} \) the HSS has only one possibly nontrivial differential \langle \mathbb{Z}/4 \rangle \to \langle \mathbb{Z}/2 \rangle \) and whether it’s 0 or not determines whether \( H_{-3} \) is \langle \mathbb{Z}/2 \rangle \) or 0. But the KSS collapses and gives \( H_{-3} = \langle \mathbb{Z}/2 \rangle \), so the aforementioned differential has to be trivial. So now the HSS gives

\[
H_{*}(\mathcal{S}^{m\lambda-4\sigma}) = \begin{cases} 
\mathbb{Z} & \text{if } * = 2m-4 \\
\langle \mathbb{Z}/4 \rangle & \text{if } -2 \leq * < 2m-4 \text{ and } * \text{ is even} \\
\langle \mathbb{Z}/2 \rangle & \text{if } * = -3 \\
\mathbb{Q} & \text{if } * = -4
\end{cases}
\]

- \( u^m_m/u^2_{2\sigma}, u^{-4}_\sigma \tilde{u}_\lambda^m, u^{-4}_\sigma \tilde{u}_\lambda^m \) generates \( \mathbb{Z} \).
- \( (u^{m-i}_\lambda\lambda a^m_\lambda)/u^2_{2\sigma}, u^{-4}_\sigma \tilde{u}_\lambda^{m-i} \tilde{a}_\lambda^i \) \( 0 \) generates \( \langle \mathbb{Z}/4 \rangle \) for \( 0 < i < m \).
- \( (w_3 a^m_\lambda)/a_{\sigma} \) \( 0 \) generates \( \langle \mathbb{Z}/2 \rangle \).
- \( (2a^m_\lambda)/u_{2\sigma}, u^{-4}_\sigma \tilde{a}_\lambda^m \) \( 0 \) generates \( \mathbb{Q} \).

10.5. The case \( n = 5 \). For \( \mathcal{S}^{m\lambda-5\sigma} \) the HSS has only one possibly nontrivial differential (for \( m \geq 2 \) and comparison with the KSS shows that differential vanishes. In degree \(-3\) for \( m > 1 \) we have an extension of \langle \mathbb{Z}/2 \rangle \) and \langle \mathbb{Z}/2 \rangle \) in all three spectral sequences, and the answer can be either \( \mathbb{Q} \) or \langle \mathbb{Z}/2 \rangle \oplus \langle \mathbb{Z}/2 \rangle \). To see which one it is, we use the multiplicative generators: \langle \mathbb{Z}/2 \rangle \) is generated on top level by \( (w_3 a^m_\lambda)/a^2_{\sigma} \) while \langle \mathbb{Z}/2 \rangle \) is generated on middle level by \( u_{\sigma}^{-5} \tilde{u}_\lambda^{m-1} \tilde{a}_\lambda \) and the question is whether we have the equality:

\[
\text{Tr}_2^2(u_{\sigma}^{-5} \tilde{u}_\lambda^{m-1} \tilde{a}_\lambda) \overset{?}{=} (w_3 a^m_\lambda)/a^2_{\sigma}
\]

The left hand side is computed by Frobenius to be \( w_5 u_{\lambda} a_{\lambda}^{m-1} \) so we ask if

\[
w_5 a_{\lambda}^{m-1} u_{\lambda} \overset{?}{=} (w_3 a^m_\lambda)/a^2_{\sigma}
\]

Multiplication by \( a^2_{\sigma} \) is an isomorphism hence we equivalently want to check

\[
a^2_{\sigma} w_5 a_{\lambda}^{m-1} u_{\lambda} \overset{?}{=} w_3 a^m_\lambda
\]

But by the Gold Relation the left hand side is 0 as \( 2w_5 = 0 \), while in the right hand side we have the generator of \( \mathbb{Z}/2 \). This means that the extension has to be trivial i.e. \langle \mathbb{Z}/2 \rangle \oplus \langle \mathbb{Z}/2 \rangle \).
For $m = 1$ we have an extension of $\langle \mathbb{Z}/2 \rangle$ and $\mathbb{Z}_-$ that resolves to $\langle \mathbb{Z}/2 \rangle \oplus \mathbb{Z}_-$ for the same reason. The answer is:

$$H_*(\mathbb{S}^{m\lambda-5\sigma}) = \begin{cases} 
\mathbb{Z}_- & \text{if } * = 2m - 5 \text{ and } m \geq 2 \\
\langle \mathbb{Z}/2 \rangle & \text{if } -1 \leq * < 2m - 5 \text{ and } * \text{ is odd} \\
\langle \mathbb{Z}/2 \rangle & \text{if } -4 \leq * < 2m - 5 \text{ and } * \text{ is even} \\
\langle \mathbb{Z}/2 \rangle \oplus \langle \mathbb{Z}/2 \rangle & \text{if } * = -3 \text{ and } m \geq 2 \\
\langle \mathbb{Z}/2 \rangle \oplus \mathbb{Z}_- & \text{if } * = -3 \text{ and } m = 1 \\
Q & \text{if } * = -5 
\end{cases}$$

- $0|u_0^{-5} a_i^m|\bar{a}_\lambda^5 \bar{b}_\lambda^m$ generates all instances of $\mathbb{Z}_-$.
- $0|u_0^{-5} a_i^{m-i} \bar{a}_\lambda^i 0$ generates all instances of $\langle \mathbb{Z}/2 \rangle$ for $0 < i \leq m - 1$.
- $(2a_i^j u_{\lambda}^{m-i})/(a_i u_{2\sigma}^2)|0|0$ generates $\langle \mathbb{Z}/2 \rangle$ for $0 < i \leq m$.
- $(w_3 a_i^n)/a_i^2|0|0$ generates the $\langle \mathbb{Z}/2 \rangle$ that appear as summands at $-3$.
- $w_3 a_i^n|u_0^{-5} \bar{a}_\lambda^m|0$ generates $Q$ at $-5$.

The multiplicative generator $(2a_i^j u_{\lambda}^{m-i})/(a_i u_{2\sigma}^2)$ is proven just like we did with $H_*(\mathbb{S}^{m\lambda-3\sigma})$ (i.e. we use the result for $H_*(\mathbb{S}^{m\lambda-6\sigma})$ and multiply by $a_i^2$).

10.6. The general case. We proceed by induction on $n$.

The computation of $H_*(\mathbb{S}^{m\lambda-n\sigma})$ for even $n \geq 6$ is exactly like that for $n = 4$:

The HSS has unknown differentials that are trivial by comparison with the KSS and there are no extension problems.

The computation of $H_*(\mathbb{S}^{m\lambda-n\sigma})$ for odd $n \geq 5$ is exactly like that for $n = 5$:

The differentials in the HSS vanish by comparison with the KSS and we have extension problems for $\langle \mathbb{Z}/2 \rangle, \langle \mathbb{Z}/2 \rangle$ and $\mathbb{Z}_- \langle \mathbb{Z}/2 \rangle$ that both resolve to trivial extensions for the same reason as the $n = 5$ case.

The results are displayed in subsections 5.5 and 5.6.

11. Proofs Part V: Preparation for $H_*(\mathbb{S}^{n\sigma-m\lambda})$

In this section and the next we will compute $H_*(\mathbb{S}^{n\sigma-m\lambda})$ for $n, m \geq 1$. As before, there are three spectral sequences of Mackey functors we will use, and this section is devoted to determining their $E_2$ terms sans differentials. We omit the multiplicative presentation for certain generators as in subsection 9.

11.1. The Homological Spectral Sequence. The HSS is

$$E^2_{p,q} = H_p(\mathbb{S}^{n\sigma}; H_q S^{-m\lambda}) \Rightarrow H_{p+q}(\mathbb{S}^{n\sigma-m\lambda})$$

For $n \geq 1$,

$$H_*(\mathbb{S}^{n\sigma}; H_{-2m}(S^{-m\lambda})) = H_*(\mathbb{S}^{n\sigma}; L) = \begin{cases} 
L^i & \text{if } * = n; \text{ even} \\
\mathbb{Z}_-^i & \text{if } * = n; \text{ odd} \\
\langle \mathbb{Z}/2 \rangle & \text{if } 2 \leq * < n \text{ and } * \text{ is even} 
\end{cases}$$

The multiplicative generators:

- $(2u_2 u_0^{n/2})/u_0^{m}|(2u_0^n)/a_i^m|\bar{a}_\lambda^i \bar{a}_\lambda^{-m}$ generates $L^i$.
- $0|(2u_0^n)/a_i^m|\bar{a}_\lambda^i \bar{a}_\lambda^{-m}$ generates $\mathbb{Z}_-$.
For $1 \leq i \leq m - 1$, 

$$H_\ast(S^{n\sigma}; H_{-2i-1}(S^{-m\lambda})) = H_\ast(S^{n\sigma}; \langle \mathbb{Z} / 4 \rangle) = \begin{cases} Q^\sharp & \text{if } \ast = n \neq 1 \\ \langle \mathbb{Z} / 2 \rangle & \text{if } 0 \leq \ast < n \text{ and } \ast \neq 1 \\ \langle \mathbb{Z} / 2 \rangle & \text{if } \ast = n = 1 \end{cases}$$

The multiplicative generators:

- $(u_{2\sigma}^{n/2} s_3)/(a_{\lambda}^{m-i} u_{\lambda}^{i-2})0$ generates $Q^\sharp$ for $\ast = n$ even.
- The middle level generator of $Q^\sharp$ for $\ast = n$ odd is $(u_{\sigma}^{n} s_3)/(a_{\lambda}^{m-i} u_{\lambda}^{i-2})$.
- $0|(a_{\sigma}^{n-2} u_{2\sigma}^{n/2} s_3)/(a_{\lambda}^{m-i} u_{\lambda}^{i-2})0$ generates $\langle \mathbb{Z} / 2 \rangle$.
- $(a_{\sigma}^{n-2} u_{2\sigma}^{n/2} s_3)/(a_{\lambda}^{m-i} u_{\lambda}^{i-2})0$ generates $\langle \mathbb{Z} / 2 \rangle$ for $0 \leq \ast < n$ even.

11.2. The Cohomological Spectral Sequence. The CSS is

$$E_2^{p,q} = H_{-p}(S^{-m\lambda}; H_{-q}S^{n\sigma}) \Rightarrow H_{-p-q}(S^{n\sigma-m\lambda})$$

and for odd $n$,

$$H_{-\ast}(S^{m\lambda}; H^n(S^{n\sigma})) = H_{-\ast}(S^{m\lambda}; \mathbb{Z}_\ast) = \begin{cases} L_- & \text{if } \ast = 2m \\ \langle \mathbb{Z} / 2 \rangle & \text{if } 3 \leq \ast < 2m \text{ and } \ast \text{ is odd} \\ \langle \mathbb{Z} / 2 \rangle & \text{if } 2 \leq \ast < 2m \text{ and } \ast \text{ is even} \end{cases}$$

The multiplicative generators:

- $\mathrm{Tr}_2((2u_{2\sigma}^{n})/(a_{\lambda}^{m})/(2u_{\sigma}^{n})/(a_{\lambda}^{m})\bar{u}_{\lambda}^{m}$ generates $L_-$
- $0|(u_{\sigma}^{n} s_3)/(a_{\lambda}^{m} \bar{u}_{\lambda}^{m})0$ generates $\langle \mathbb{Z} / 2 \rangle$

Finally, $H_{-\ast}(S^{-m\lambda}; \langle \mathbb{Z} / 2 \rangle) = \langle \mathbb{Z} / 2 \rangle$ concentrated in degree 0. So $H_{-\ast}(S^{-m\lambda}; H_iS^{n\sigma})$ is generated by $(a_{\sigma}^{n-2} u_{2\sigma}^{n})/(a_{\lambda}^{n})$ for $0 \leq i < n/2$.

11.3. The Kunneth Spectral Sequence. The KSS is

$$E_2^{p,q} = \mathrm{Tor}_{\mathbb{Z}}^{p+2}(H_{i}S^{n\sigma-(m-1)\lambda}, L) \Rightarrow H_{p+q}(S^{n\sigma-m\lambda})$$

This is the Kunneth spectral sequence for $S^{n\sigma-(m-1)\lambda} \wedge S^{-\lambda}$ and we have used that $H_i S^{-\lambda} = L$ concentrated in degree $\ast = -2$. A free resolution of $L$ is

$$0 \rightarrow \mathbb{Z} \xrightarrow{\sum g_{x}} \mathbb{Z}_{C_4} \xrightarrow{\rho} \mathbb{Z}_{C_4} \xrightarrow{\lambda} L \rightarrow 0$$

where $x \in \mathbb{Z}[C_4]$ corresponds to a generator of $C_4$ (recall that $\mathbb{Z}_{C_4}$ is the fixed point Mackey functor on $\mathbb{Z}[C_4]$).

We list only the nonzero Tor’s below, dropping the subscript $\mathbb{Z}$ from the notation:

- $\mathrm{Tor}^0(L, \mathbb{Z}_-) = L_-$
- $\mathrm{Tor}^2(L, \langle \mathbb{Z} / 4 \rangle) = \langle \mathbb{Z} / 4 \rangle$

31
The existence of $\text{Tor}^2$ terms means that the KSS can now have potentially nonvanishing differentials and more complicated extension problems. As a result the computations in the next section are slightly more involved compared to those in section 10.

Still, this is slightly better than the worst case scenario that is nonvanishing $\text{Tor}^3$. In general, for finite cyclic $G$ the abelian category of $\mathbb{Z}$-Mackey functors has projective dimension 3 ([BSW17]).

12. Proofs Part VI: $H_*(S^{n\sigma-m\lambda})$

The computation of $H_*(S^{n\sigma-m\lambda})$ depends heavily on the parity of $n$ and we distinguish three cases: even $n$, $n = 1$ and odd $n \geq 3$.

In the even $n$ case, we compute $H_*(S^{n\sigma-m\lambda})$ for $m = 1, 2, 3$ separately before we can perform induction. The case $n = 1$ is straightforward enough to do for all $m$ at once, while for odd $n \geq 3$ we again compute the special cases $m = 1, 2, 3$ and then induct on $m$.

We make use of all three spectral sequences HSS, CSS and KSS and play them off against each other.

12.1. The case of even $n$ and $m = 1$. The HSS for $S^{n\sigma-\lambda}$ collapses with no extensions (for dimensional reasons) to give

$$H_*(S^{n\sigma-\lambda}) = \begin{cases} L^2 & \text{if } * = n - 2 \\ \langle \mathbb{Z} / 2 \rangle & \text{if } 0 \leq * \leq n - 4 \text{ and } * \text{ is even} \end{cases}$$

The multiplicative generators for $L^2$ and $\langle \mathbb{Z} / 2 \rangle$ are obtained immediately from the HSS and CSS respectively and they are:

- $(2u_{2^r}^2u_{2^s}^{-1}) / u_\lambda | (2u_{2^r}^2) / u_\lambda | \overline{a}_\lambda \overline{a}_\lambda^{-1}$ generates $L^2$.
- $(a_{2^r}^{2^i}u_{2^s}) / a_\lambda | 0 | 0$ generates $\langle \mathbb{Z} / 2 \rangle$ for $0 \leq i < n / 2 - 1$.

Note that by the Gold relation, the mod 2 reduction of $(2u_{2^r}^2) / u_\lambda$ is $(a_{2^r}^{2^i}u_{2^s}^{-1}) / a_\lambda$.

12.2. The case of even $n$ and $m = 2$. The KSS for $S^{n\sigma-2\lambda}$ collapses giving the answer with the exception of degree $n - 4$ for $n \geq 4$. There is an extension problem of $L, \langle \mathbb{Z} / 2 \rangle$ in all three spectral sequences and there are only two possibilities for
that extension:
\[
0 \to L \to L \oplus \langle \mathbb{Z} / 2 \rangle \to \langle \mathbb{Z} / 2 \rangle \to 0
\]
\[
0 \to L \to L^2 \to \langle \mathbb{Z} / 2 \rangle \to 0
\]
By the CSS, the extension is \(L^2\) iff \((2u_{2\sigma}^{n/2}/u_\lambda^2)\) exists and its mod 2 reduction is \((u_\sigma^4u_{2\sigma}^{n/2-2}/a_\lambda^2)\). If this were true, then we would have the following commutative diagram:

\[
\begin{array}{ccc}
\mathbb{Z} & \xrightarrow{u_\lambda^2} & \mathbb{Z}(u_{2\sigma}^{n/2}) \\
\xrightarrow{a_\lambda^2} & & \xrightarrow{a_\lambda^2} \\
& \mathbb{Z}/4(u_{2\sigma}^{n/2}a_\lambda^2) & \xrightarrow{u_\lambda^2} \\
& \xrightarrow{a_\lambda^2} & \mathbb{Z}/2(a_\sigma^4u_{2\sigma}^{n/2-2})
\end{array}
\]

Note that in the lower part of the diagram, since \(a_\lambda^2u_\lambda = 0\) by the Gold Relation, the \(u_\lambda^2\) map is trivial. So we have

\[
\begin{array}{ccc}
\mathbb{Z} & \xrightarrow{\text{mod 4}} & \mathbb{Z}/4 \\
\xrightarrow{\text{mod 2}} & & \xrightarrow{0} \\
& \mathbb{Z}/2 & \xrightarrow{0}
\end{array}
\]

which clearly doesn’t commute.

Therefore the extension has to be \(L \oplus \langle \mathbb{Z} / 2 \rangle\), which means that \((2u_{2\sigma}^{n/2}/u_\lambda^2)\) does not exist. As we remarked above, this only happens for \(n \geq 4\); for \(n = 2\) we only have an \(L\) so there is no extension and the elements \((2u_{2\sigma}/u_\lambda^2)\) and \(a_\sigma^2/a_\lambda^3\) do not exist.

In conclusion we have

\[
H_\ast(S^{n\sigma-2\lambda}) = \begin{cases} 
\mathbb{Q}^\ast & \text{if } * = n - 3 \\
L \oplus \langle \mathbb{Z} / 2 \rangle & \text{if } * = n - 4 \text{ and } n \geq 4 \\
L & \text{if } * = -2 \text{ and } n = 2 \\
\langle \mathbb{Z} / 2 \rangle & \text{if } 0 \leq * < n - 4 \text{ and } * \text{ is even}
\end{cases}
\]

- \(u_{2\sigma}^{n/2}s_3|u_\lambda^2s_3|0\) generates \(\mathbb{Q}^\ast\)
- \((4u_{2\sigma}^{n/2})/u_\lambda^2|(2u_\sigma^2)/\bar{u}_\lambda^2|\bar{u}_\sigma^n\bar{u}_\lambda^{-2}\) generates all instances of \(L\) (both as a summand and nonsummand).
- \((a_{2\sigma}^{n-2}u_{2\sigma}/a_\lambda^3)|0|0\) generates all instances of \(\langle \mathbb{Z} / 2 \rangle\) for \(0 \leq i < n/2 - 1\)

12.3. The case of even \(n\) and \(m = 3\). The KSS for \(S^{n\sigma-3\lambda}\) collapses with an usual extension problem of \(L\) and \(\langle \mathbb{Z} / 2 \rangle\) at \(n - 6\) and \(n \geq 6\). The answer is \(L^2\) iff \((2u_{2\sigma}^{n/2}/u_\lambda^3)\) exists, but if it did then \((2u_{2\sigma}^{n/2}/u_\lambda^2)\) would also exist, contradicting...
the computation of $S^{n\sigma - 2\lambda}$ in the preceding subsection. We conclude:

$$H_*(S^{n\sigma - 3\lambda}) = \begin{cases} 
Q^2 & \text{if } * = n - 3 \\
\langle \mathbb{Z} / 4 \rangle & \text{if } * = n - 5 \\
L \oplus \langle \mathbb{Z} / 2 \rangle & \text{if } * = n - 6 \text{ and } n \geq 6 \\
L & \text{if } * = n - 6 \text{ and } n = 2, 4 \\
\langle \mathbb{Z} / 2 \rangle & \text{if } 0 \leq * \leq n - 4 \text{ and } * \text{ is even and } * \neq n - 6
\end{cases}$$

- $(u^{n/2}_1 s_3)/a_\lambda|(u^n s_3)/a_\lambda|0$ generates $Q^2$
- $u^{n/2}_2 (s_3/u_\lambda)|(u_\sigma s_3)/a_\lambda|0$ generates $\langle \mathbb{Z} / 4 \rangle$
- $(a^{22}_\sigma u_\lambda^{n/2 - 1} - a^3_\lambda)/0|0$ generates all instances of $\langle \mathbb{Z} / 2 \rangle$ for $2 \leq i \leq n/2$.
- $(4u_\sigma^{n/2})/u^3_\lambda|(2u_\sigma)/a^3_\lambda|\tilde{u}_\lambda^2 \tilde{u}_\lambda^{-3}$ generates all instances of $L$.

12.4. **The general case of even $n$.** We proceed by induction, with the case of $H_* S^{n\sigma - m\lambda}$ for $m \geq 4$ being treated exactly the same as for $m = 3$. The answer is given in subsection 5.7.

12.5. **The case of $n = 1$.** By comparing the HSS (collapses with one extension) and CSS (has differentials but no extensions) we get:

$$H_*(S^{\sigma - m\lambda}) = \begin{cases} 
L_- & \text{if } * = 1 - 2m \text{ and } m \geq 2 \\
\mathbb{Z}^- & \text{if } * = -1 \text{ and } m = 1 \\
\langle \mathbb{Z} / 2 \rangle & \text{if } -2m + 2 \leq * \leq -2 \text{ and } * \text{ is even} \\
\langle \mathbb{Z} / 2 \rangle & \text{if } -2m + 3 \leq * \leq -3 \text{ and } * \text{ is odd}
\end{cases}$$

- $(a_\sigma s_3)/u^{m - 2}_\lambda|(2u_\sigma)/(u_\sigma)/a^m_\lambda|\tilde{u}_\lambda \tilde{u}_\lambda^{-m}$ generates $L_-$ for $m \geq 2$
- $0|(2u_\sigma)/\tilde{u}_\lambda^2 \tilde{u}_\lambda^2$ generates $\mathbb{Z}^-$ for $m = 1$
- $0|(u_\sigma s_3)/(u^{m - i}_\lambda \tilde{u}_\lambda^{-i - 2})|0$ generates $\langle \mathbb{Z} / 2 \rangle$ for $2 \leq i \leq m$.
- $(a_\sigma s_3)/(a^{m - i}_\lambda \tilde{u}_\lambda^{-i - 2})|0|0$ generates $\langle \mathbb{Z} / 2 \rangle$ for $2 \leq i < m$

Therefore,

$$\text{Tr}_2^d ((2u_\sigma)/a^2_\lambda) = a_\sigma s_3$$

We also note that while $a_\sigma/a_\lambda$ does not exist, the element $a^2_\sigma/a_\lambda$ does exist by the $n = 2$ computation.

12.6. **The case of odd $n \geq 3$ and $m = 1$.** The HSS for $S^{n\sigma - \lambda}$ collapses with no extensions to give:

$$H_*(S^{n\sigma - \lambda}) = \begin{cases} 
\mathbb{Z}^+ & \text{if } * = n - 2 \\
\langle \mathbb{Z} / 2 \rangle & \text{if } 0 \leq * \leq n - 3 \text{ and } * \text{ is even}
\end{cases}$$

- $(2u^n_\sigma)/\tilde{u}_\lambda|\tilde{u}_\lambda b_\lambda^{-1}|0$ generates $\mathbb{Z}^+$. 
- $(a^{n - 2}_\sigma u_\lambda)/a_\lambda|0|0$ generates $\langle \mathbb{Z} / 2 \rangle$ for $0 \leq i \leq (n - 3)/2$
12.7. The case of odd $n \geq 3$ and $m = 2$. For $S^{n \sigma - 2 \lambda}$ the HSS and CSS comparison reveals:

$$H_*(S^{n \sigma - 2 \lambda}) = \begin{cases} Q^\sharp & \text{if } * = n - 3 \\ \langle Z / 2 \rangle & \text{if } * = n - 4 \\ \langle Z / 2 \rangle \oplus \langle Z / 2 \rangle & \text{if } * = n - 5 \text{ and } n \geq 5 \\ \langle Z / 2 \rangle & \text{if } * = n - 5 \text{ and } n = 3 \\ L_- & \text{if } * = n - 6 \\ \langle Z / 2 \rangle & \text{if } 0 \leq * \leq n - 7 \text{ and } * \text{ is even} \end{cases}$$

- $(a^3_\sigma u_{2 \sigma}^{(n-3)/2} / a^3_\lambda | u^2_\sigma s_3 | 0)$ generates $Q^\sharp$.
- $a_\sigma u_{2 \sigma}^{(n-1)/2} s_3 (2u^0_\sigma / \bar{a}_\lambda^2 | \bar{a}_\lambda^{-2})$ generates $L_-$.
- $(a^0_\sigma - 2i u_{2 \sigma}^i) / a^2_\lambda | 0 | 0)$ generates $\langle Z / 2 \rangle$ for $0 \leq i \leq (n - 5) / 2$.

So $a^3_\sigma / a^3_\lambda$ exists and

$$\bar{s}_3 = \text{Res}_2^4(a^3_\sigma / a^3_\lambda) / u^3_\sigma$$

12.8. The case of odd $n \geq 3$ and $m = 3$. For $S^{n \sigma - 3 \lambda}$ comparison of the KSS and HSS gives the answer with the exception of an extension problem of $\langle Z / 2 \rangle$ and $\langle Z / 2 \rangle$ for $n \geq 5$. There are two possible extensions, $Q^\sharp$ and $\langle Z / 2 \rangle \oplus \langle Z / 2 \rangle$, and to determine which one it is, we use the multiplicative generators: The middle level generator of $\langle Z / 2 \rangle$ is $u^0_\sigma(\bar{s}_3 / \bar{a}_\lambda)$ and the top level generator of $\langle Z / 2 \rangle$ is $(a^0_\sigma u_{2 \sigma}^{(n-5)/2} / a^3_\lambda)$ so it all rests on whether or not

$$\text{Res}_2^4(a^3_\sigma / a^3_\lambda) \equiv u^3_\sigma(\bar{s}_3 / \bar{a}_\lambda)$$

But we already know that $a^3_\sigma / a^3_\lambda$ and $a^0_\sigma / a_\lambda$ both exist, the latter generating the top level of a $\langle Z / 2 \rangle$ thus having trivial restriction. Therefore

$$\text{Res}_2^4(a^3_\sigma / a^3_\lambda) = \text{Res}_2^4(a^3_\sigma / a^3_\lambda) \text{ Res}_2^4(a^0_\sigma / a_\lambda) = 0$$

can't be the generator $u^0_\sigma(\bar{s}_3 / \bar{a}_\lambda)$ and the extension is trivial. We conclude:

$$H_*(S^{n \sigma - 3 \lambda}) = \begin{cases} Q^\sharp & \text{if } * = n - 3 \\ \langle Z / 2 \rangle & \text{if } * = n - 4 \\ \langle Z / 2 \rangle \oplus \langle Z / 2 \rangle & \text{if } * = n - 5 \text{ and } n \geq 5 \\ \langle Z / 2 \rangle & \text{if } * = n - 5 \text{ and } n = 3 \\ L_- & \text{if } * = n - 6 \\ \langle Z / 2 \rangle & \text{if } 0 \leq * \leq n - 7 \text{ and } * \text{ is even} \end{cases}$$

- $(a^3_\sigma u_{2 \sigma}^{(n-3)/2} / a^3_\lambda | u^0_\sigma s_3 | \bar{a}_\lambda | 0)$ generates $Q^\sharp$.
- $(a_\sigma u_{2 \sigma}^{(n-1)/2} s_3 / a_\lambda | 0 | 0)$ generates $\langle Z / 2 \rangle$ at degree $n - 4$.
- $(a^0_\sigma - 2i u_{2 \sigma}^i) / a^2_\lambda | 0 | 0)$ generates all instances of $\langle Z / 2 \rangle$ for $0 \leq i \leq (n - 5) / 2$.
- $0(\bar{u}^0_\sigma s_3 / \bar{a}_\lambda | 0)$ generates all instances of $\langle Z / 2 \rangle$.
- $(a_\sigma u_{2 \sigma}^{(n-1)/2} s_3 / u_\lambda | (2u^0_\sigma / a^2_\lambda | u^0_\sigma \bar{a}_\lambda^{-3})$ generates $L_-$.

12.9. The general case of odd $n \geq 3$. We proceed by induction, with $H_*S^{n \sigma - m \lambda}$ for $m \geq 4$ being treated exactly like the $m = 3$ case. The answer is given in subsection 5.8.
13. Appendix - The relations

In this appendix we prove that the secondary relations (the Frobenius relations combined with the additive structure and the presentation of the generators given in section 5) and the four "extra" relations

\[ a_\sigma^2 u_\lambda = 2u_2 a_\lambda \]  
(1)
\[ x_{1,1} \frac{a_\sigma}{a_\sigma^2} = \frac{w_3}{a_\lambda} \]  
(2)
\[ x_{1,1} \frac{a_\sigma}{a_\lambda} = \frac{2s_3}{a_\sigma} \]  
(3)
\[ x_{1,1} \frac{a_\sigma}{u_\lambda} = \frac{a_\sigma s_3}{u_2 a_\sigma} \]  
(4)

can be used to generate all other relations in \( \pi^C_4(HZ) \). The first extra relation is the Gold relation and the final two follow from the definition of \( s_3 \). The second is actually redundant (we only use it as a convenient way to pass between \( x_{1,1} \) and \( w_3 \)) and follows from the Gold in this way: First,

\[ \frac{w_3}{a_\sigma} \frac{2u_2 a_\sigma}{a_\lambda} = \frac{x_{1,1}}{a_\sigma^2} \]  
(5)

To see this, note that multiplication by \( a_\sigma^2 \) is an isomorphism so equivalently:

\[ \frac{2u_2 a_\sigma}{a_\lambda} = x_{1,1} \]

This is proven by appealing to the Frobenius relation:

\[ w_3 \frac{2u_2 a_\sigma}{a_\lambda} = \text{Tr}_4^2(u_\sigma^{-1}) \frac{2u_2 a_\sigma}{a_\lambda} = \text{Tr}_4^2 \left( u_\sigma^{-1} \frac{2u_2 a_\sigma}{a_\lambda} \right) = \text{Tr}_4^1(\bar{a}_\sigma^{-1} \bar{a}_\lambda^{-1}) = x_{1,1} \]

Next note that

\[ a_\lambda \cdot \frac{2u_2 a_\sigma}{u_\lambda} = a_\sigma^2 \]  
(6)

as multiplying by \( u_\lambda \) is an isomorphism (the map \( \mathbb{Z}/2 \rightarrow \mathbb{Z}/2, a_\sigma^2 \mapsto a_\sigma^2 u_\lambda = 2u_2 a_\lambda \) is an isomorphism). By (5) and (6),

\[ w_3 = \frac{x_{1,1}}{a_\sigma^2} a_\lambda \]

So the map \( a_\lambda \) is an isomorphism \( \mathbb{Z}/2 \rightarrow \mathbb{Z}/2, x_{1,1}/a_\sigma^2 \mapsto w_3 \), hence we can write

\[ \frac{x_{1,1}}{a_\sigma^2} = \frac{w_3}{a_\lambda} \]

To prove that the secondary relations and the four extra relations are enough to generate all others, it is enough to compute the product of any two generators \( a \in H^C_k(S^{n+\sigma+m\lambda}) \) and \( b \in H^C_k(S^{n'+\sigma+m'\lambda}) \) as a linear combination of the generators in \( H^C_{k+k'}(S^{(n+n')\sigma+(m+m')\lambda}) \), using only the relations above.

What follows is an exhaustive list of all these products that need to be computed and the results of the computations. The proofs are rather brief; consult subsection 4.2 for the strategy employed. To keep the length of the list reasonable, we have made the following omissions:
1 We omit products where one factor is a transfer, as these reduce to the $C_2$ case by the Frobenius relation:

$$\text{Tr}_2^4(x) y = \text{Tr}_2^4(x \text{Res}_4^2 y)$$

2 We omit products that are trivial for degree reasons.

3 We omit products where both factors are in $H_k S^{n} t + m$ for $k, n, m \geq 0$. This part is polynomially generated by the Euler and orientation classes modulo the Gold relation (1).

4 We omit products that can immediately be computed through the following fact: If $x/y, z/w$ and $(xz)/(yw)$ all generate the homology groups they live in, then

$$\frac{x z}{y w} = \frac{x z}{y w}$$

Note that this applies only when we have cyclic homology in the degrees of $x/y, z/w$ and $(xz)/(yw)$.

With all that said, we are ready to present the list (we only label the relations/equations that we reference later in the proofs of other relations):

- The following relations compute the product of $a_\sigma$ with the other generators:

  $$a_\sigma \cdot \frac{s_3}{u_2^i u_\lambda} = \frac{x_{1,1}}{u_2^i u_\lambda} a_\sigma$$

  $$a_\sigma \cdot \frac{2s_3}{u_2^i u_\lambda} = \frac{2a_\sigma}{a_\sigma u_2^i u_\lambda}$$

  $$a_\sigma \cdot \frac{2a_\sigma}{a_\sigma} = \frac{2a_\sigma}{a_\sigma}$$

  $$a_\sigma \cdot \frac{2u_2^i}{u_\lambda} = \frac{2a_\sigma}{a_\sigma u_2^i} u_\lambda$$

  $$a_\sigma \cdot \frac{2u_2^i}{u_\lambda} = \frac{2a_\sigma}{a_\sigma u_2^i} u_\lambda$$

  $$a_\sigma \cdot \frac{2u_2^i}{u_\lambda} = \frac{2a_\sigma}{a_\sigma u_2^i} u_\lambda$$

Note: If $i = 0$ in the first equation or $j = 0$ in the 2nd-4th equations then we get a negative exponent in a denominator. When this happens that means the product is 0.

**Proof.** After clearing denominators (multiplying by the denominators in the right hand side), all but the third equation reduce to the Gold relation. The third instead reduces to (3). \(\square\)

- The following relations compute the product of $u_2^i$ with the other generators:

  $$u_2^i \cdot \frac{2s_3}{a_\sigma} = \frac{a_\sigma s_3}{a_\sigma i + 1}$$

  $$u_2^i \cdot \frac{2a_\sigma}{a_\sigma} = a_\sigma a_\sigma i - 1 u_\lambda$$

**Proof.** Both reduce to the Gold as usual. For the second equation, multiplication by $a_\sigma$ is an isomorphism as can be seen directly from the right hand side. \(\square\)
• The following relations compute the product of $a_\lambda$ with the other generators:

\[
\frac{2s_3}{a_\sigma u_{2\sigma}^i u_{2\sigma}^j a_\lambda} = \frac{x_{1,1}}{u_{2\sigma}^i u_{2\sigma}^j} \quad \frac{2u_{2\sigma}^i}{u_\lambda} = a_\sigma^2 u_{2\sigma}^{i-1}
\]

(8)

Proof. Both reduce to the Gold after clearing denominators. □

• The following relations compute the product of $u_\lambda$ with the other generators:

\[
\begin{align*}
\frac{2s_3}{a_\sigma u_{2\sigma}^i a_\lambda} &= 0 \\
\frac{2s_3}{u_\lambda} &= 0 \\
\frac{a_\lambda u_3}{a_\lambda^i u_{2\sigma}^i} &= 0, \ i \geq 3
\end{align*}
\]

Proof. The first two relations are deduced as follows:

\[
\begin{align*}
\frac{2s_3}{a_\sigma u_{2\sigma}^i a_\lambda} &= 0 \cdot \frac{x_{1,1}}{a_\sigma^2 u_{2\sigma}^i a_\lambda^i} \iff u_\lambda \frac{2s_3}{u_{2\sigma}} = 0 \iff 2a_\sigma = 0 \\
\frac{2s_3}{u_\lambda} &= 0 \cdot \frac{a_\lambda u_3}{a_\lambda^{i+2} u_{2\sigma}^i} \iff a_\lambda^2 u_\lambda \frac{u_3}{u_{2\sigma}} = 0 \iff \text{Gold}
\end{align*}
\]

For the last relation, if $j \geq 2$ the homology group in the degree of the product is 0 so we may assume $j = 1$ and further that $i = 3$ (we can factor higher powers of $a_\sigma$ out of the quotient). Then,

\[
\frac{a_\lambda^3}{a_\lambda} = 0 \cdot a_\sigma u_{2\sigma}^i \iff a_\sigma^3 u_\lambda = 0 \iff \text{Gold}
\]

□

• The remaining relations involving $s_3$ are:

\[
\begin{align*}
\frac{s_3}{u_{2\sigma}^i a_\lambda} &= \frac{2a_\lambda}{a_\sigma u_{2\sigma}^i a_\lambda} = \frac{x_{1,1}}{u_{2\sigma}^i u_{2\sigma}^j} \\
2s_3 &= \frac{2a_\lambda}{a_\sigma} = 0 \\
\frac{2s_3}{a_\sigma u_{2\sigma}^i a_\lambda} &= \frac{s_3}{a_\sigma u_{2\sigma}^i a_\lambda} = 2 \cdot \frac{s_3}{u_{2\sigma}^i a_\sigma}
\end{align*}
\]

Proof. The first reduces to (4) as usual. The second reduces to the relation we just proved, while the final one reduces to (7):

\[
\begin{align*}
\frac{2s_3}{a_\sigma u_{2\sigma}^i a_\lambda} &= \frac{2a_\lambda}{a_\sigma} = \frac{x_{1,1}}{a_\sigma u_{2\sigma}^i a_\lambda} \iff 2s_3 \frac{2a_\lambda}{a_\sigma} = 0 \\
\frac{2s_3}{a_\sigma u_{2\sigma}^i a_\lambda} &= \frac{s_3}{u_{2\sigma}^i a_\lambda} = \frac{2s_3}{a_\sigma u_{2\sigma}^i} \iff 2s_3 \frac{2a_\lambda}{a_\sigma} = 2s_3
\end{align*}
\]

□
• The remaining relations involving \(x_{1,1}\) are:

\[
\begin{align*}
\frac{x_{1,1}}{a_\sigma u_{2 \sigma} a_\lambda^k} \cdot 2u_{2 \sigma} &= 2 \frac{s_3}{u_{2 \sigma} a_\lambda^k} \\
\frac{x_{1,1}}{a_\sigma u_{2 \sigma} a_\lambda^k} \cdot 2u_{2 \sigma} &= \frac{x_{1,1}}{a_\sigma u_{2 \sigma} a_\lambda^k}
\end{align*}
\]

\textit{Proof.} For the first relation we perform a denominator exchange:

\[
\begin{align*}
\frac{x_{1,1}}{a_\sigma u_{2 \sigma} a_\lambda^k} \cdot 2u_{2 \sigma} &= 2 \frac{s_3}{u_{2 \sigma} a_\lambda^k} \iff \frac{x_{1,1}}{a_\sigma u_{2 \sigma} a_\lambda^k} 2u_{2 \sigma} = 2s_3 \iff \frac{s_3}{u_{2 \sigma}} 2u_{2 \sigma} = s_3
\end{align*}
\]

\(\Box\)

• The remaining relations involving \(w_3\) are:

\[
\begin{align*}
\frac{w_3}{a_\sigma u_{2 \sigma} a_\lambda^k} \cdot a_\sigma^3 &= \frac{x_{1,1}}{a_\sigma u_{2 \sigma} a_\lambda^k} \\
\frac{w_3}{a_\sigma u_{2 \sigma} a_\lambda^k} \cdot 2u_{2 \sigma} &= \frac{x_{1,1}}{a_\sigma u_{2 \sigma} a_\lambda^k}
\end{align*}
\]

\textit{Proof.} For the first relation we may assume \(i \geq 1\) (otherwise we have a transfer) and then the equality is implied by (2). The second relation is implied by (5).

\(\Box\)

• The remaining relation involving \(u_\lambda/a_{2 \sigma}\) is:

\[
\frac{u_\lambda}{a_{2 \sigma} a_\lambda} a_\sigma^3 = 0
\]

\textit{Proof.} Follows immediately from the Gold.

\(\Box\)

• The remaining relations involving \((2a_\lambda)/a_\sigma\) are:

\[
\begin{align*}
\frac{2a_\lambda}{a_\sigma} \frac{2a_\lambda}{a_\sigma} &= 2 \frac{a_\lambda u_\lambda}{u_{2 \sigma}} \\
\frac{2a_\lambda}{a_\sigma} \frac{a_\sigma^3}{a_\lambda} &= 0 \\
\frac{2a_\lambda}{a_\sigma} \frac{2u_{2 \sigma}}{u_\lambda} &= 0
\end{align*}
\]

\textit{Proof.} For the first two:

\[
\begin{align*}
\frac{2a_\lambda}{a_\sigma} \frac{2a_\lambda}{a_\sigma} = 2 \frac{a_\lambda u_\lambda}{u_{2 \sigma}} \iff \frac{2a_\lambda}{a_\sigma} \cdot \left(\frac{2a_\lambda}{a_\sigma} \cdot \frac{2a_\lambda}{a_\sigma} \right) = 2a_\lambda u_\lambda \iff (7)
\end{align*}
\]

\[
\frac{2a_\lambda}{a_\sigma} \frac{a_\sigma^3}{a_\lambda} = 0 \cdot a_\sigma^2 \iff 2a_\lambda \cdot \frac{a_\sigma^3}{a_\lambda} = 0 \cdot a_\sigma^3
\]

39
For the third we may assume $j = 1$ and then
\[
\frac{2a^i_\sigma}{u_{2\sigma}} \cdot \frac{2u_{2\sigma}}{u_\lambda} = 0 \cdot a_\sigma a^{-1}_\lambda \iff \frac{2a^i_\lambda}{u_\lambda} \cdot \frac{2u_{2\sigma}}{u_\lambda} = 0 \cdot a_\sigma a^{-1}_\lambda \iff (8)
\]

\[\square\]

• The remaining relations involving $2u_{2\sigma}/u_\lambda$ are:
\[
\frac{2u_{2\sigma}^j}{u_\lambda} \cdot \frac{2u_{2\sigma}^i}{u_\lambda} = \frac{4u_{2\sigma}^{i+j}}{u_\lambda^2} + \frac{a_{\sigma}^i u_{2\sigma}^{i+j-2}}{a_{\lambda}^2}
\]
\[
\frac{a_{\sigma}^i}{a_{\lambda}^k} \cdot \frac{2u_{2\sigma}^j}{u_\lambda} = \frac{a_{\sigma}^{i+2} u_{2\sigma}^{j-1}}{a_{\lambda}^{k+1}}
\]

Proof. We explained how to get the first relation at the end of subsection 4.2.
For the second, note that the element in the left-hand side is 2-torsion so no torsion-free generator can appear in the right-hand side. Thus we have
\[
\frac{a_{\sigma}^i}{a_{\lambda}^k} \cdot \frac{2u_{2\sigma}^j}{u_\lambda} = \frac{a_{\sigma}^{i+2} u_{2\sigma}^{j-1}}{a_{\lambda}^{k+1}} \iff a_\sigma a_\lambda \frac{2u_{2\sigma}^j}{u_\lambda} = a_\sigma a_\lambda \iff (8)
\]

\[\square\]
