We discuss a general bipartite-like representation and Schmidt decomposition of an arbitrary pure state of \( N \) indistinguishable fermions, based on states of \( M < N \) and \( (N-M) \) fermions. It is directly connected with the reduced \( M \)- and \( (N-M) \)-body density matrices (DMs), which have the same spectrum in such states. The concept of \( M \)-body entanglement emerges naturally in this scenario, generalizing that of one-body entanglement. Rigorous majorization relations satisfied by the normalized \( M \)-body DM are then derived, which imply that the associated entropy will not increase, on average, under a class of operations which have these DMs as post-measurement states. Moreover, such entropy is an upper bound to the bipartite entanglement entropy generated by a class of operations which map the original state to a bipartite state of \( M \) and \( N-M \) effectively distinguishable fermions. Analytic evaluation of the spectrum of \( M \)-body DMs in some strongly correlated fermionic states is also provided.

I. INTRODUCTION

A remarkable feature of quantum mechanics is the existence of correlations between quantum systems that cannot be emulated by their classical counterpart. Entanglement is the most celebrated manifestation of such correlations and it has been object of intense research in quantum physics, particularly within the field of quantum information theory [1]. Particle indistinguishability is another fundamental feature of quantum mechanics, lying at the heart of condensed matter physics and quantum field theories. An interesting problem combining these two fundamental concepts is that of the study and quantification of correlations between indistinguishable fermions, a topic that has received increasing attention in the last years [2]. Indistinguishability poses a nontrivial difficulty in the study of quantum correlations, because the notion of entanglement is intimately connected with that of local operations, and the latter are possible only if the constituents of the system can be distinguished. Different approaches to this problem have been considered, like mode entanglement [3, 4], extensions based on correlations between observables [5–10] and entanglement beyond symmetrizability [11–21], which is independent of the choice of single particle (sp) basis. The relation between these forms of entanglement has been analysed by different authors [2, 3, 16, 20, 22–24] as well as the question regarding whether symmetrization correlations should be addressed as entanglement [30, 31].

In this paper we explore the generalization of the bipartite formulation devised in [25] for the notion of one-body entanglement, a measure of correlations beyond (anti)symmetrization introduced in [20]. We start by considering operators on the fermion Fock space of the system creating general \( N \)-fermion states, which are used to show that a general \( N \)-fermion state can be always written as a bipartite-like state of \( M < N \) and \( N-M \) fermions. This bipartite representation is connected with the definition of the \( M \) and \( N-M \)-body reduced density matrices (DMs) [27, 28] in a way that closely resembles the case of bipartite states of distinguishable constituents. The ensuing \((M,N-M)\) Schmidt-like decomposition of the state determines the diagonal form of these DMs, entailing they share the same non-zero eigenvalues. Pushing forward this analogy we propose to link the correlations between \( M \) and \( N-M \)-body observables, which we call \( M \)-body entanglement, to the mixedness of the \( M \)-body DM, as formalized by eigenvalue majorization. We introduce a family of entropic measures of such correlations and show that there exists a class of operations not increasing the amount of these correlations in any \( N \)-fermion state. Finally, we prove the existence of a family of quantum maps converting \( N \)-fermion states into bipartite states of effectively distinguishable \( M \) and \( N-M \)-fermions, in the sense of occupying orthogonal sp subspaces. Conversion by means of any of these maps is such that the entanglement entropy of the bipartite target state is bounded from above by the \( M \)-body entropy, assigning the latter a clear operational meaning. Explicit examples of \( M \)-body DMs and their eigenvalues in some physical states are also provided.

II. FORMALISM

We consider a sp space \( \mathcal{H} \) of finite dimension \( D \), spanned by fermion operators \( c_i, c_i^\dagger, i = 1, \ldots, D \) satisfying the anticommutation relations

\[
\{c_i, c_j^\dagger\} = \delta_{ij}, \quad \{c_i, c_j\} = \{c_i^\dagger, c_j^\dagger\} = 0.
\]

We also define the \( M \)-fermion creation operators

\[
C^{(M)}_{\alpha} = c_{i_1}^\dagger \cdots c_{i_M}^\dagger,
\]

where \( i_1 < i_2 < \ldots < i_M \) and \( \alpha = (i_1, \ldots, i_M) \) labels all \( (D)_M = \frac{D!}{M!(D-M)!} \) distinct sets of \( M \) sp states sorted in
increasing order. These operators satisfy
\[ \langle 0 | C^{(M)}_{\alpha} C^{(M)}_{\alpha'} | 0 \rangle = \delta_{MM'} \delta_{\alpha \alpha'}, \]
\[ \sum_{\alpha} C^{(M)}_{\alpha} C^{(M)}_{\alpha} = \left( \frac{\hat{N}}{M} \right), \]
where \( \hat{N} = \sum_{i} c_i^\dagger c_i \) is the fermion number operator and \( \left( \frac{\hat{N}}{M} \right) \) is the operator taking the value \( \left( \frac{N}{M} \right) \) in a state of \( N \) fermions \( \left( \frac{N}{M} \right) | \Psi \rangle = \frac{\hat{N}}{M} | \Psi \rangle \), with \( \left( \frac{N}{1} \right) = \hat{N}, \left( \frac{N}{2} \right) = \frac{\hat{N}^2 - \hat{N}}{2} \), etc. Eq. (4) is a generalization of the number operator, representing the number of “\( M \)-fermion composites”. The states \( C^{(M)}_{\alpha} | 0 \rangle \) are Slater Determinants (SDs) and form, for all \( \alpha \) and \( 0 \leq M \leq D \), an orthonormal basis of the \( 2^M \)-dimensional Fock space associated to \( \mathcal{H} \).

A normalized pure state \( | \Psi \rangle \) of \( N \) fermions \( \hat{N} | \Psi \rangle = N | \Psi \rangle \) can then be expanded in this basis as
\[ | \Psi \rangle = \frac{1}{N!} \sum_{i_1, \ldots, i_N} \Gamma_{i_1 \cdots i_N} c_{i_1}^\dagger \cdots c_{i_N}^\dagger | 0 \rangle, \]
\[ = \sum_{\alpha} \Gamma^{(N)}_{\alpha} C^{(N)}_{\alpha} | 0 \rangle, \]
where \( \Gamma_{i_1 \cdots i_N} \) are the elements of a fully antisymmetric tensor and \( \Gamma^{(N)}_{\alpha} = \langle 0 | C^{(N)}_{\alpha} | \Psi \rangle = \Gamma_{i_1 \cdots i_N} \) (for \( \alpha = (i_1, \ldots, i_N) \), \( i_1 < i_2 < \cdots < i_N \)), with
\[ \sum_{\alpha} | \Gamma^{(N)}_{\alpha} |^2 = \frac{1}{N!} \sum_{i_1, \ldots, i_N} | \Gamma_{i_1 \cdots i_N} |^2 = 1. \]

Thus, \( | \Gamma^{(N)}_{\alpha} |^2 = \langle \Psi | C^{(M)}_{\alpha} C^{(M)}_{\alpha} | \Psi \rangle \) is the probability of finding the \( N \) sp states \( \alpha \) occupied in \( | \Psi \rangle \).

A. The \( (M, N-M) \) representation and the \( M \)-body DM

For \( 0 \leq M \leq N \) we can also rewrite the state \( | \Psi \rangle \) as
\[ | \Psi \rangle = \left( \frac{N}{M} \right)^{-1} \sum_{\alpha, \beta} \Gamma^{(M)}_{\alpha \beta} C^{(M)}_{\alpha} C^{(N-M)}_{\beta} | 0 \rangle, \]
where \( \Gamma^{(M)}_{\alpha \beta} = \Gamma^{(M,N-M)}_{\alpha \beta} \) is given by
\[ \Gamma^{(M)}_{\alpha \beta} = \langle 0 | C^{(N-M)}_{\beta} C^{(M)}_{\alpha} | \Psi \rangle = \Gamma_{i_1 \cdots i_{N-M} j_1 \cdots j_{N-M}}, \]
for \( \alpha = (i_1, \ldots, i_M), \beta = (j_1, \ldots, j_{N-M}) \), and the sum in (8) is over all \( (D)_M \) and \( (N-M)_D \) distinct sets of \( M \) and \( N-M \) sp states respectively, with (7) implying
\[ \sum_{\alpha, \beta} | \Gamma^{(M)}_{\alpha \beta} |^2 = \left( \frac{N}{M} \right). \]

We will denote the expression (8) as the \( (M, N-M) \)-body representation of the \( N \)-fermion state (5). It is a bipartite-like expansion of \( | \Psi \rangle \) in orthogonal \( M \)- and \( (N-M) \)-fermion states, leading to a \( \left( \frac{D}{M} \right) \times \left( \frac{D}{N-M} \right) \) matrix representation \( \Gamma^{(M)} \) of the original tensor \( \Gamma \) in (5). Of course, decompositions \( (M, N-M) \) and \( (N-M, M) \) are equivalent, with
\[ \Gamma^{(N-M)} = (-1)^{M(N-M)} (\Gamma^{(M)})^T, \]
due to the antisymmetry of \( \Gamma \) (\( T \) denotes transpose). Eq. (9) is the trivial \( (N, 0) \) representation.

From the antisymmetry of \( \Gamma \) it also follows that
\[ C^{(M)}_{\alpha} | 0 \rangle = \sum_{\beta} \Gamma^{(M)}_{\alpha \beta} C^{(N-M)}_{\beta} | 0 \rangle, \]
which represents the (unnormalized) state of the remaining \( N-M \) fermions when the \( M \) sp states labelled by \( \alpha \) are occupied in \( | \Psi \rangle \). Eqs. (12) and (3) imply that the \( M \)-body density matrix \( \rho^{(M)} \), whose elements are defined as
\[ \rho^{(M)}_{\alpha \alpha'} := \langle \Psi | C^{(M)}_{\alpha'} C^{(M)}_{\alpha} | \Psi \rangle, \]
can be expressed in terms of \( \Gamma^{(M)} \) as
\[ \rho^{(M)} = \Gamma^{(M)} \Gamma^{(M)^T}, \]
i.e. \( \rho^{(M)}_{\alpha \alpha'} = \sum_{\beta} \Gamma^{(M)}_{\alpha \beta} \Gamma^{(M)^T}_{\beta \alpha'} \), in the same way as the reduced density matrix \( \rho^{A} = Tr_B | \Psi_{AB} \rangle \langle \Psi_{AB} | \) is obtained from a general state \( | \Psi_{AB} \rangle = \sum_{i_A, j_B} G_{ij} | i_A, j_B \rangle \) of a system of two distinguishable components \( \rho^{A}_{i'i'} = \langle i'_{A'} | i_A \rangle \otimes I_B | \Psi_{AB} \rangle \). In particular, \( \rho^{(M)}_{\alpha \alpha} \) is the probability of finding the \( M \) sp states specified by \( \alpha \) occupied in \( | \Psi \rangle \). Eq. (14) is a positive semidefinite \( (\frac{D}{M}) \times (\frac{D}{M}) \) matrix which determines the average of any \( M \)-body operator \( \hat{O}^{(M)} = \sum_{\alpha, \alpha'} C^{(M)}_{\alpha} C^{(M)}_{\alpha'} | \Psi \rangle \langle \Psi | \) through
\[ \langle \Psi | \hat{O}^{(M)} | \Psi \rangle = Tr [ \rho^{(M)} \hat{O}^{(M)} ]. \]
Its trace is given by
\[ Tr [ \rho^{(M)} ] = \left( \frac{N}{M} \right), \]
as implied by (11) or (10). We also notice that
\[ C^{(N-M)}_{\beta} | 0 \rangle = \sum_{\alpha} \Gamma^{(N-M)}_{\beta \alpha} C^{(M)}_{\alpha} | 0 \rangle, \]
Hence, using (11) the partner \((N-M)\)-body DM, of elements \( \rho^{(N-M)}_{\beta \beta'} = \langle \Psi | C^{(N-M)}_{\beta'} C^{(N-M)}_{\beta} | \Psi \rangle \), is
\[ \rho^{(N-M)} = \Gamma^{(N-M)} \Gamma^{(N-M)^T} = (\Gamma^{(M)})^T \Gamma^{(M)^T}, \]
which shows it has the same non-zero eigenvalues (and hence the same trace) as the \( M \)-body DM (14) [36, 38], as discussed in [16] in more detail.
In particular, for $M = 1$, $C^{(1)}_\uparrow = c^\dag_\uparrow$ and we recover from Eq. [5] the $(1, N - 1)$ representation [35]
\[
|\Psi\rangle = \frac{1}{\sqrt{N}} \sum_{i, \alpha} \Gamma^{\uparrow}_\alpha c^\dag_{\alpha i} C^{(N - 1)}_{\alpha i} |0\rangle,
\] (19)
where the $D \times (\frac{D}{N - 1})$ matrix $\Gamma^{(1)}$ determines the one-body DM (also denoted as SDPM) $\rho^{(1)} = \langle \Psi | c^\dag_\uparrow c^\downarrow | \Psi \rangle$ through
\[
\rho^{(1)} = \Gamma^{(1)}(\Gamma^{(1)})^\dag.
\] (20)

We finally remark that Eq. [5] is a particular case of the more general $k$-particle representation of the state [5],
\[
|\Psi\rangle = \frac{M_1! \ldots M_k!}{M!} \sum_{\alpha_1, \ldots, \alpha_k} \Gamma^{M_1 \ldots M_k} C^{(M_1)}_{\alpha_1} \ldots C^{(M_k)}_{\alpha_k} |0\rangle, (21)
\]
where $\Gamma^{M_1 \ldots M_k} = (0)C^{(M_1)}_{\alpha_1} \ldots C^{(M_k)}_{\alpha_k} |\Psi\rangle = \Gamma_{i_1 \ldots i_N}$ for $\alpha_j = (i_1, \ldots, i_{M_j}), \ldots, \alpha_k = (i_{N - M_k+1}, \ldots, i_N)$ and $\sum_{j=1}^k M_j = N$, with $k \leq N$ and sums running over all $(\frac{D}{M})$ sets of $M_j$ sp states. The basic expansion [15] corresponds to $k = N$ and $M_j = 1$ for $j = 1, \ldots, N$.

**B. The $(M, N - M)$ Schmidt representation**

We can now employ the singular value decomposition of the matrix $\Gamma^{(M)}$,
\[
\Gamma^{(M)} = U^{(M)} D^{(M)} V^{(N-M)} \nonumber
\] (22a)
\[
D^{(M)} = \sqrt{\lambda}_\nu^{(M)} \delta_{\nu \nu'}, (22b)
\]
where $U^{(M)}, V^{(N-M)}$ are $D \times (\frac{D}{M})$ and $(\frac{D}{N-M}) \times (\frac{D}{N-M})$ unitary matrices and $D^{(M)} \equiv D^{(M,N-M)}$ a $D \times (\frac{D}{N-M})$ diagonal matrix with non-negative elements. Here $\lambda^{(M)}_\nu$ denote the square of the singular values of $\Gamma^{(M)}$, i.e. the eigenvalues of $\Gamma^{(M)} \Gamma^{(M)*} = \rho^{(M)}$ or equivalently $\Gamma^{(M)*} \Gamma^{(M)} = \rho^{(N-M)}$, which have the same spectrum (except for the number of zero eigenvalues). It then becomes possible to rewrite Eq. [5] in the Schmidt-like diagonal form
\[
|\Psi\rangle = \sqrt{\lambda}_\nu^{(M)} A^{(M)}_\nu B^{(N-M)}_\nu |0\rangle, (23)
\]
where $n_M$ is the rank of $\Gamma^{(M)}$ and
\[
A^{(M)}_\nu = \sum_{\alpha} U^{(M)}_{\alpha} C^{(M)}_{\alpha}, (24)
\]
\[
B^{(N-M)}_\nu = \sum_{\beta} V^{(N-M)}_{\beta} C^{(N-M)}_{\beta}, (25)
\]
are “collective” operators creating, respectively, $M$ and $N - M$ fermions in generally entangled (i.e., non-SD’s for $M \geq 2$) states. Nevertheless, since they are unitarily related to the original operators $C^{(M)}_\alpha$ and $C^{(N-M)}_{\beta}$, they still satisfy, for $1 \leq M \leq N - 1$,
\[
\langle 0 | A^{(M)}_\nu A^{(M)}_{\nu'} | 0 \rangle = \delta_{\nu \nu'} = \langle 0 | B^{(N-M)}_\nu B^{(N-M)}_{\nu'} | 0 \rangle, (26)
\]
\[
\sum_\nu A^{(M)}_\nu A^{(M)}_{\nu} = \left( \begin{array}{c} \sqrt{N} \\ \frac{M}{M} \end{array} \right) = \sum_\nu B^{(N-M)}_\nu B^{(N-M)}_{\nu}, (27)
\]
\[
\langle 0 | B^{(N-M)}_\nu A^{(M)}_{\nu} | \Psi \rangle = \sqrt{\lambda}_\nu^{(M)} \delta_{\nu \nu'}. (28)
\]
Moreover, Eqs. (12), (22) and (24) lead to
\[
A^{(M)}_\nu | \Psi \rangle = \sqrt{\lambda}_\nu^{(M)} B^{(N-M)}_\nu | \Psi \rangle, (29)
\]
such that $B^{(N-M)}_\nu | 0 \rangle$ is the state of remaining $N - M$ fermions when $M$ fermions are measured to be in the “normal” or “natural” state $A^{(M)}_\nu | 0 \rangle$. Eqs. (20) (29) also imply that the normal operators $A^{(M)}_\nu$, $B^{(N-M)}_\nu$ diagonalize the $M$- and $(N - M)$-body DM:
\[
\langle \Psi | A^{(M)}_\nu A^{(M)}_{\nu'} | \Psi \rangle = \langle U^{(M)} \rho^{(M)} U^{(M)*} \rangle_{\nu \nu'} = \lambda^{(M)}_\nu \delta_{\nu \nu'}, (30)
\]
\[
\langle \Psi | B^{(N-M)}_\nu B^{(N-M)}_{\nu'} | \Psi \rangle. (31)
\]
For $M = 1$ we recover from (24) (25) the diagonal representation of the one-body DM $\rho^{(1)} [55], with $A^{(1)}_\nu = \sum_{\nu} U_{\nu} c^\dag_{\nu}$, the operators creating a fermion in the ensuing natural sp orbitals.

In the trivial case $M = N$, $\rho^{(N)}$ has a single non-zero eigenvalue $\lambda^{(N)}_1 = 1$ associated with the operator $A^{(N)}_1 = \sum_\alpha \Gamma^{(N)}_\alpha c^{(N)}_{\alpha}$ creating the state. On the other hand, in an $N$-fermion SD, which can be always written as $|\Psi\rangle = c^\dag_1 \ldots c^\dag_N |0\rangle$ by a suitable choice of the operators $c^\dag_1$, $\rho^{(N)}$ has just $N$ non-zero eigenvalues $\lambda^{(N)}_j = 1$, associated with the $(N - M)$ operators $A^{(N-M)}_\nu = c^\dag_1 \ldots c^\dag_j$,
\[
1 \leq i_1 < \ldots < i_M \leq N, with support on the $N$ occupied sp states, satisfying $\langle \Psi | A^{(N-M)}_\nu A^{(N-M)}_{\nu'} | \Psi \rangle = \delta_{\nu \nu'}.
\]
For instance, the decomposition of an $N = 3$ SD $c^\dag_1 c^\dag_2 c^\dag_3 |0\rangle$ for $M = 1$ is just $|\Psi\rangle = \frac{1}{3} \sum_{i=1}^3 c^\dag_i B^{(2)}_i |0\rangle$, with $B^{(2)}_1 = c^\dag_1 c^\dag_2, B^{(2)}_2 = -c^\dag_1 c^\dag_3, B^{(2)}_3 = c^\dag_2 c^\dag_3$ and $\langle c^\dag_i c^\dag_j \rangle = \delta_{ij} = \langle B^{(2)}_i B^{(2)}_j \rangle$ for $i, j \leq 3$. Similarly for general $N$. Thus, in a SD $\rho^{(M)}$ is idempotent: $\langle \rho^{(M)} \rangle^2 = \rho^{(M)} \forall M$.

And for a general pure two-fermion state $|\Psi_2\rangle = \frac{1}{2} \sum_{i < j} \Gamma_{ij} c^\dag_i c^\dag_j |0\rangle$, with $\Gamma_{ij} = -\Gamma_{ji}$, the (non-zero) singular values of $\Gamma^{(1)} = \Gamma$ for the $M = 1$ decomposition (1, 1), and hence the eigenvalues of $\rho^{(1)} = \Gamma \Gamma^\dag$, are always two-fold degenerate [111], such that the natural operators can be paired as $A^{(1)}_\nu = c^\dag_\nu, A^{(1)}_{\nu'} = c^\dag_{\nu'}$ for $\nu = \lambda^{(1)}_\nu$, with $B^{(1)}_\nu = c^\dag_\nu, B^{(1)}_{\nu'} = -c^\dag_{\nu'}$ and $c^\dag_{\nu(\nu')} = \sum_{\nu} U_{\nu \nu'} c^\dag_{\nu}$. Then Eq. (23) leads to
\[
|\Psi_2\rangle = \frac{1}{2} \sum_\nu \sqrt{\lambda}_\nu^{(1)} (A^{(1)}_\nu B^{(1)}_{\nu} + A^{(1)}_{\nu'} B^{(1)}_{\nu'}) |0\rangle (31a)
\]
\[
= \sum_\nu \sqrt{\lambda}_\nu^{(1)} c^\dag_{\nu} c^\dag_{\nu'} |0\rangle, (31b)
\]
where (31b) is the well-known Slater decomposition of a two-fermion state (12, 13), with \( c_i^\dagger c_{i'}^\dagger = \lambda_{i'}^{(1)} \delta_{ii'} \), \( (c_i^\dagger c_{i'}^\dagger) = 0 \) and \( \sum_i \lambda_i^{(1)} = 1 \). For \( D = 4 \) (two fermions in 4 sp levels), there are just two distinct eigenvalues \( \lambda_{i'}^{(1)} \), given by \( \lambda_{i'} = \frac{1 \pm \sqrt{1 - 4C}}{2} \), with \( C = 2 |\Gamma_{12} \Gamma_{34} - \Gamma_{13} \Gamma_{24} + \Gamma_{14} \Gamma_{23}| = 2 \sqrt{\lambda_{i'} \lambda_{i''}} \). The fermionic concurrence (11, 13, 20) and (31b) can be rewritten as \( \sqrt{\lambda_{i'} c_i^\dagger c_i + \sqrt{\lambda_{i''} c_{i''}^\dagger c_{i''}}} |0\rangle \).

C. The eigenvalues of the \( M \)-body DM

While the eigenvalues \( \lambda_i^{(1)} = \langle \Psi | c_i^\dagger c_i | \Psi \rangle \) of the SPDM \( \rho^{(1)} \) always lie in the interval \( [0, 1] \) (as \( c_i^\dagger \) are standard fermion operators), for \( M \geq 2 \) those of \( \rho^{(M)} \) can be greater than 1 when \( |\Psi\rangle \) is not a SD, since the normal operators \( A_0^{(M)} \) will in general no longer be a single product of \( M \) fermion creation operators. These operators may exhibit boson-like features for even \( M \geq 2 \), or in general features of boson + fermion creation operators for odd \( M \geq 3 \).

We first note that any operator \( A^{(M)} = \sum_i \gamma_i c_i^{\dagger} \) creating \( M < N \) fermions can be expanded in the normal operators (24) as \( A^{(M)} = \sum_i \gamma_i c_i^{\dagger} \), with \( \gamma_i = \sum_i U_{ii'}^\dagger \gamma_{i'} \). Hence, using (30),

\[
\langle \Psi | A^{(M)} A^{(M)} | \Psi \rangle = \sum_i \lambda_i^{(1)} |\gamma_i|^2,
\]

with \( \langle 0 | A^{(M)} A^{(M)} | 0 \rangle = \sum_i |\gamma_i|^2 \). Thus for normalized operators satisfying \( \langle 0 | A^{(M)} A^{(M)} | 0 \rangle = 1 \), the largest eigenvalue \( \lambda_{\text{max}}^{(M)} \) of \( \rho^{(M)} \) bounds any such average:

\[
\langle \Psi | A^{(M)} A^{(M)} | \Psi \rangle \leq \lambda_{\text{max}}^{(M)}.
\]

In a SD, \( \lambda_{\text{max}}^{(M)} = 1 \) and \( \langle \Psi | A^{(M)} A^{(M)} | \Psi \rangle \leq 1 \) for all \( M \) and normalized \( A^{(M)} \). This bound can of course be broken in more general fermion states.

For instance, let us define, assuming even sp dimension \( D \), the collective pair creation operator

\[
A^{\dagger} = \frac{1}{\sqrt{D/2}} \sum_{i=1}^{D/2} c_{2i-1}^\dagger c_{2i}^\dagger, \tag{34}
\]

which satisfies \( [A^{\dagger}, N] = -2A^{\dagger} \) and

\[
[A^{\dagger}, A^{\dagger}^\dagger] = -\frac{2}{D} N, \tag{35}
\]

implying \( \langle 0 | A A^{\dagger} | 0 \rangle = 1 \). We then consider the normalized states \( 0 \leq k \leq \frac{D}{2} \)

\[
\langle \Psi_{2k} \rangle = \frac{(A^{\dagger})^k}{k! \sqrt{\frac{2}{D}} \sqrt{\binom{D/2}{k}}} \langle 0 | 0 \rangle, \tag{36}
\]

which contains \( k \) such pairs and hence \( N = 2k \) fermions, and where \( c_{2i-1} = 0 \), \( c_{2i}^\dagger = 1 \), \( c_{2i-1}^\dagger = 0 \), \( c_{2i} = 1 \), and \( N = 2k \) fermions.

When \( \mu \neq \nu \), the two-body DM \( \lambda^{(2)}_{\text{max}} \) has eigenvalues \( \lambda^{(2)}_{\nu} \), with \( \lambda^{(2)}_{\text{max}} \approx D + 1 \), associated with the normal operator \( A^{\dagger} \), which satisfies \( \lambda^{(2)}_{\text{max}} > 1 \) for \( 2 \leq k \leq \frac{D}{2} \). For \( k = 1 \), \( \lambda^{(2)}_{\text{max}} = 1 + (N - 1) \frac{2}{D} \).

All remaining \( \langle D/2 \rangle - 1 \) eigenvalues of \( \rho^{(2)} \) are small and identical to (see Appendix A)

\[
\lambda^{(2)}_{\text{rest}} = \frac{4k(k-1)}{D(D-2)} \leq 1, \tag{40}
\]

such that \( \lambda^{(2)}_{\text{max}} + (\langle D/2 \rangle - 1) \lambda^{(2)}_{\text{rest}} = \lambda^{(2)}_{\text{max}} \) (Eq. (41)). Since \( \langle \Psi | A A^{\dagger} | \Psi \rangle \leq 1 \) in any SD (Eq. (33)), (39) clearly signals as well that \( \langle \Psi_{2k} \rangle \) is not a SD.

The dominant eigenvalue (39) is maximum in the half-filled case \( k = \frac{D}{2} \), where \( \lambda^{(2)}_{\text{max}} \approx D(1 + 2/D)^2/8 \) increases linearly with \( D \) for large \( D \), and can then become arbitrarily large. For \( D \gg k \), \( \lambda^{(2)}_{\text{max}} \approx k = N/2 \) is just the number of pairs, whereas \( \lambda^{(2)}_{\text{min}} \approx (2k/D)^2 \) becomes very small. As seen from (35)–(36), for \( D \to \infty \) at fixed \( N \), \( A^{\dagger} \) becomes a “true” boson \( \{A, A^{\dagger}\} \to 1 \), with \( \langle \Psi_{2k} \rangle \to \langle A^{\dagger} \rangle^k \mid 0 \rangle \) a condensate of \( k \)-bosons.

Eigenvalues of odd \( M \) DM’s can also exceed 1. For instance, in an odd state \( \mid \Psi_{2k+1} \rangle = c_{2k+1}^\dagger \mid \Psi_{2k} \rangle \) where we have enlarged the sp space with one additional state, the largest eigenvalue of the three-body DM \( \rho^{(3)} \) is again given by (39): \( \mid \Psi_{2k+1} \rangle = c_{2k+1}^\dagger A_{CD+1}^{\dagger} \mid \Psi_{2k+1} \rangle = \lambda^{(2)}_{\text{max}} \geq 1 \). It corresponds to the number of pairs times the number of “single fermions” (1). The eigenvalues of \( \rho^{(3)} \) in the even state (35) can also be analytically determined (see Appendix A). Its largest eigenvalue,

\[
\lambda^{(3)}_{\text{max}} = \frac{2k(k-1) - \frac{1}{D} (k-1)^2}{D-2} \tag{41}
\]
while smaller than (39), still satisfies \( \lambda_{\text{max}}^{(3)} > 1 \) for \( 1 + \sqrt{D/2} < k < D/2 \), reaching \( \frac{2D}{k} \) at \( k = \frac{D}{2} \) for \( D \gg 1 \). Fig. 4 depicts \( \lambda_{\text{max}}^{(M)} \) vs. \( k \) for \( M \leq 4 \) in the states (39).

From (37) it also follows that \( (A^{\dagger})^m A^m |\Psi_{2k}\rangle \propto |\Psi_{2k}\rangle \) for \( m \leq k \). Thus, the largest eigenvalue of the 2m-body DM in the state (36) is associated to the normalized operator \( A^{(2m)\dagger} = m! \sqrt{\left(\frac{D}{m}\right)^m} \) (see also Appendix A):

\[
\lambda_{\text{max}}^{(2m)} = \frac{(A^{\dagger})^m A^m}{m! \sqrt{\left(\frac{D}{m}\right)^m}} |\Psi_{2k}\rangle = \frac{k!}{m! (D/2 - k + m)!} \frac{D/2}{m!} |\Psi_{2k}\rangle,
\]

which generalizes Eq. (39) \( (m = 1 \) case). Thus, \( \lambda_{\text{max}}^{(2m)} > 1 \) for \( m < k < D/2 \), with \( \lambda_{\text{max}}^{(2m)} \approx \binom{k}{m} \) if \( D \gg k \). Similarly, in the odd state \( |\Psi_{2k+1}\rangle = c_{D+1}^\dagger |\Psi_{2k}\rangle \), \( \lambda_{\text{max}}^{(2m+1)} = \lambda_{\text{max}}^{(2m)} \).

The eigenvalues of \( \rho^{(M)} \) can also be all smaller than 1. For instance, in a \( N = D/2 \) GHZ-like fermion state

\[
|\Psi_{D/2}\rangle = \frac{1}{\sqrt{2}} |c_1^\dagger \ldots c_{D/2}^\dagger + c_{D/2+1}^\dagger \ldots c_D^\dagger\rangle |0\rangle,
\]

all nonzero eigenvalues of \( \rho^{(M)} \) are easily seen to be

\[
\lambda_{\nu}^{(M)} = 1/2,
\]

for \( 1 \leq M \leq N - 1 \), \( 2^{(N-M)} \) degenerate. This example shows that distinct \( N \)-fermion states which appear identical at the one-body level, like (39) and (43) for \( N = D/2 \) \( (\rho^{(1)} = \frac{1}{2} I) \), can differ significantly at higher \( M \)-body levels \( \lambda_1^{(2)} = 1/2 \) in (43) while \( \lambda_1^{(2)} = \frac{D}{2} \left(1 + \frac{2}{D}\right) > 1 \) in (39) for \( k = D/4 \) and \( D \geq 8 \).

### III. M-BODY ENTANGLEMENT

#### A. Mixedness of the M-body DM

The Schmidt-like decomposition (23) of an \( N \)-fermion pure state, and the fact that the positive numbers \( \lambda_{\nu}^{(M)} \) represent the non-zero eigenvalues of both the \( M \) and \( (N - M) \)-body DM’s, naturally lead to a notion of \( M \)-body entanglement based on the spread of these eigenvalues. It characterizes the correlations between \( M \) and \( (N - M) \)-body observables in an \( N \)-fermion state. More precisely, given two pure states \( |\Psi\rangle, |\Phi\rangle \) of \( N \) fermions, we will say that \( |\Psi\rangle \) is not less \( (M, N - M) \)-entangled, or simply not less \( M \)-body entangled than \( |\Phi\rangle \), if \( \rho^{(M)} \) is more mixed than \( (\text{or equally mixed as}) \rho^{(M)} \), i.e., if their eigenvalues satisfy the majorization relation

\[
\lambda(\rho^{(M)}) < \lambda(\rho^{(M)}),
\]

where \( \lambda(\rho^{(M)}) \) denotes the spectrum of \( \rho^{(M)} \), sorted in decreasing order. Explicitly, Eq. (45) means that all inequalities (46)

\[
\sum_{\nu=1}^{j} \lambda_{\nu}(\rho^{(M)}) \leq \sum_{\nu=1}^{j} \lambda_{\nu}(\rho^{(M)}), \quad j = 1, \ldots, (D/2) - 1,
\]

are to be satisfied by the sorted eigenvalues \( \lambda_{\nu} \) of \( \rho^{(M)} \) and \( \rho^{(M)} \), with equality for \( j = (D/2) \), implying that those of \( \rho^{(M)} \) are more spread out than those of \( \rho^{(M)} \). Of course, one may likewise employ the partner DM \( \rho^{(N - M)} \) in (46), since they share the same non-zero eigenvalues. For \( M = 1 \) we recover the concept of one-body entanglement, determined by the SPDM \( \rho^{(1)} \) (22, 23).

Eq. (45) is analogous to that satisfied by local reduced states in systems of distinguishable components (where it warrants that \( |\Psi\rangle \) can be converted to \( |\Phi\rangle \) by LOCC operations (12, 13)). Notice, however, that majorization provides a partial ordering, entailing that two states may be incomparable according to previous criterion.

For example, in an \( N \)-fermion SD, \( \rho^{(M)} \) presents just \( 2^{(M)} \) non-zero eigenvalues equal to 1, while in the GHZ-like state (43), all \( 2^{(N-M)} \) non-zero eigenvalues of \( \rho^{(M)} \) are equal to \( 1/2 \) for \( M < N \), implying

\[
\lambda(\rho^{(M)}) < \lambda(\rho^{(M)}),
\]

for \( 1 \leq M \leq N - 1 \). Then the state (43) is more entangled than a SD at any \( M \)-body level \( (1 \leq M \leq N - 1) \).

However, in the pair condensate \( |\Psi_{2k}\rangle \) of Eq. (46) with \( 2 \leq k < D/2 - 1 \), while clearly \( \lambda(\rho^{(1)}_{2k}) < \lambda(\rho^{(1)}_{2k}) \) (Eq. (53)), neither \( \lambda(\rho^{(2)}_{2k}) < \lambda(\rho^{(2)}_{2k}) \) nor \( \lambda(\rho^{(2)}_{2k}) < \lambda(\rho^{(2)}_{2k}) \) are fulfilled, since the largest eigenvalue of \( \rho^{(2)}_{2k+1} \) is greater than 1 whereas remaining \( (D/2 - 1) \) eigenvalues are non-zero and lower than 1 (Eqs. (39)–(40)), with \( (D/2) > (N/2) \) for \( D > N \). Hence, SDs no longer provide the least...
mixed two-body DM. The same occurs with the three-body DM when its largest eigenvalue in the state (36) exceeds 1 (Eq. (21)), in which case \( \lambda(\rho_{2k}) < \lambda(\rho_{SD}) \) and \( \lambda(\rho_{SD}) < \lambda(\rho_{2k}) \).

### B. M-body entropies

Associated with previous definition (45), we may first consider the M-body entropies

\[
E_f^{(M)}(|\Psi\rangle) = S_f(\rho^{(M)}) = S_f(\rho^{(N-M)}),
\]

\[
= \sum_{\nu} f[\lambda_{\nu}(\rho^{(M)})],
\]

where \( S_f(\rho) = \text{Tr} f(\rho) \) is a trace-form entropy (44), with \( f : \mathbb{R}_{\geq 0} \rightarrow \mathbb{R}_{\geq 0} \) a strictly concave non-negative function complying with \( f(0) = 0 \). These entropies will satisfy

\[
E_f^{(M)}(|\Psi\rangle) \geq E_f^{(M)}(|\Phi\rangle)
\]

whenever Eq. (45) is fulfilled (40, 11, 46).

Eq. (38) is particularly suitable for defining a one-body entanglement entropy (24, 32) since \( \lambda_1^{(1)} \in [0,1] \) and standard entropic measures can be employed. For \( M \geq 2 \) it is possible to employ some bosonic-like entropy, obtained for \( f(\lambda) = -\lambda \log \lambda + (1+\lambda) \log(1+\lambda) \) (such that \( \sum_{\nu} f(\lambda_{\nu}) \) represents the von Neumann entropy of independent bosons in the grand canonical ensemble with average occupation numbers \( \lambda_{\nu} \)), which is just an example of an increasing concave function of \( \lambda \) satisfying \( f(0) = 0 \).

A second possibility, strongly motivated by the majorization relations derived in the next subsections, is to consider the entropy of the normalized densities

\[
\rho_n^{(M)} = \rho^{(M)}/(N_M),
\]

which have eigenvalues \( \lambda_n^{(M)}/(N_M) \in [0,1] \) and satisfy \( \text{Tr} [\rho_n^{(M)}] = 1 \). In this case we may employ any entropic measure \( S_f(\rho) = \text{Tr} f(\rho) \) intended for standard probabilities and define an associated M-body entropy as

\[
E_{n_f}^{(M)}(|\Psi\rangle) = S_f(\rho_{n_f}) = S_f(\rho_{n_f}^{(N-M)}).
\]

In particular, the von Neumann entropy \( S(\rho) = -\text{Tr} \rho \log_2 \rho \) leads to \( S(\rho^{(M)}) = S(\rho^{(M)})/N_M + \log_2 N_M \). Other Schur-concave functions (10) of \( \rho^{(M)} \) can also be used. Since at fixed \( N \) Eq. (45) is fully equivalent to

\[
\lambda(\rho_{n_f}) < \lambda(\rho_{\Phi_f}),
\]

as all eigenvalues are just rescaled by the same factor, it will also imply \( E_{n_f}^{(M)}(|\Psi\rangle) \geq E_{n_f}^{(M)}(|\Phi\rangle) \). And any pair of \( N \)-fermion states states incomparable with (45) will remain incomparable with (52), and vice versa.

On the other hand, Eq. (52) can also be used to compare the mixedness of reduced DMs \( \rho_n^{(M)} \) for states with distinct \( N \), as \( \rho_n^{(M)} \) has fixed trace, implying

\[
\lambda(\rho_n^{(M)}) < \lambda(\rho_{n_f}) \Rightarrow E_{n_f}^{(M)}(|\Psi\rangle) \geq E_{n_f}^{(M)}(|\Phi\rangle) \quad (53)
\]

We finally remark that the converse of Eq. (45) does not hold in general: Only if the entropic inequality \( E_{n_f}^{(M)}(|\Psi\rangle) \geq E_{n_f}^{(M)}(|\Phi\rangle) \) holds for all concave functions \( f \) (and not just a particular choice) it can be ensured that \( \lambda(\rho^{(M)}) < \lambda(\rho_{\Phi_f}) \) (44). And this implies \( \lambda(\rho^{(M)}) < \lambda(\rho^{(M)}) \) only when \( \rho^{(M)} \) and \( \rho_{\Phi_f}^{(M)} \) have the same trace, i.e. \( |\Psi\rangle \) and \( |\Phi\rangle \) the same fermion number. For states with distinct \( N \) Eq. (45) is to be replaced by (52).

### C. Operations not increasing the M-body entropy

Let us now determine the basic operations which do not increase the M-body entropy (21). We first note that one-body unitary transformations

\[
|\Psi\rangle \rightarrow U|\Psi\rangle, \quad U = \exp[-i \sum_{i,j} H_{ij} c_i^\dagger c_j],
\]

where \( H^\dagger = H \), lead to unitary transformations of all M-body DMs, thus leaving their eigenvalues and hence M-body entanglement unchanged: Since \( U|\Psi\rangle = \sum_{i,j} U_{ij}^* \Psi_i \) with \( U = \exp[-i H] \), then \( \rho^{(M)} \rightarrow U\rho^{(M)}U^\dagger \) and \( \rho^{(M)} \rightarrow U^{(M)}\rho^{(M)}U^{(M)}\). Theorem 1: The quantum operation described by the Kraus operators

\[
M_j^{(1)} = \frac{c_j}{\sqrt{N}}, \quad j = 1, \ldots, D
\]

which satisfy \( \sum_{j=1}^D M_j^{(1)*} M_j^{(1)} = \mathbb{1}_N = \mathbb{1}_X \) within the subspace of states with definite fermion number \( N \), does not increase, on average, the mixedness of the normalized M-body DMs \( \rho^{(M)} = \rho^{(M)}/(N_M) \) for \( 1 \leq M \leq N - 1 \), and implies the majorization relation

\[
\lambda(\rho_{n_f}^{(M)}) < \sum_j p_j \lambda(\rho_{\Phi_f}^{(M)}),
\]

between the spectrum of the initial and post-measurement normalized M-body DMs.
In \( \rho_{\alpha i}^{(M)} = \rho^{(M)} / \langle M \rangle \) are the normalized \( M \)-body DMs determined by the post-selected states

\[
\rho_j = p_j^{-1} M_j^{(1)} \rho M_j^{(1)\dagger} = \frac{c_j \rho c_j^\dagger}{\langle c_j^\dagger c_j \rangle},
\]

(58)

while \( p_j \) is the probability of outcome \( j \):

\[
p_j = \text{Tr} [\rho M_j^{(1)\dagger} M_j^{(1)}] = \frac{\langle c_j^\dagger c_j \rangle}{N},
\]

(59)

with \( \sum_{j=1}^{D} p_j = 1 \). This measurement, with \( D \) distinct outcomes, corresponds for instance to the detection of a single fermion through its momentum or sp energy (labelled by \( j \)), with \( p_j \) the ensuing state of remaining fermions. Notice that Eq. (57) implies

\[
S_f(\rho_{\alpha i}^{(M)}) \geq S_f(\sum_j p_j \lambda(\rho_{ji}^{(M)})) \geq \sum_j p_j S_f(\rho_{ji}^{(M)}),
\]

(60)

for any Schur-concave function of \( \rho_{\alpha i}^{(M)} \), including in particular the entropies (51). Thus, Theorem 1 implies that the entropy \( S_f(\rho_{\alpha i}^{(M)}) \) of the normalized \( M \)-body DMs will not increase, on average, after such operation. For pure states this means that the \( M \)-body entropy (51) will on average not increase, and will in general decrease, after such measurement:

\[
E^{(M)}_{n_f}(\langle \Psi \rangle) \geq \sum_j p_j E^{(M)}_{n_f}(\langle \Psi_j \rangle),
\]

(61)

where \( \langle \Psi_j \rangle = M_j |\Psi_j\rangle / \sqrt{p_j} = c_j |\Psi_j\rangle / \langle c_j^\dagger c_j \rangle \) is the state after outcome \( j \). For mixed states \( \rho \) with definite \( N \), Eq. (61) implies a similar inequality

\[
E^{(M)}_{n_f}(\rho) \geq \sum_j p_j E^{(M)}_{n_f}(\rho_j),
\]

(62)

for the convex-roof extension of (51), the \( M \)-body entanglement of formation \( E^{(M)}_{n_f}(\rho) = \min \sum_i q_i E^{(M)}_{n_f}(\langle \Psi_i \rangle) \), where the minimum is over all representations (55) of \( \rho \) as convex mixture of pure states with definite \( N \). Eq. (62) follows from (61) by using the representation of \( \rho \) minimizing \( E^{(M)}_{n_f}(\rho) \), such that \( E^{(M)}_{n_f}(\rho) = \sum_i q_i E^{(M)}_{n_f}(\langle \Psi_i \rangle) \geq \sum_j q_j E^{(M)}_{n_f}(\langle \Psi_j \rangle) \geq \sum_j p_j E^{(M)}_{n_f}(\rho_j) \), where \( p_j = \sum_i q_i p_{ij} \) and \( p_{ij} = \langle \Psi_i | c_j^\dagger c_j \Psi_i \rangle / N \).

Proof of Eq. (57): Let \( \rho \) be the state of an \( N \) fermion system upon which the operation defined by the operators (56) is performed. After outcome \( j \) is obtained, the elements of the \( M \)-body DM \( \rho_j \) determined by the ensuing state (58) are, for \( M \leq N-1 \),

\[
\rho_j^{(M)} \alpha \alpha' = p_j^{-1} \text{Tr} M_j^{(1)} \rho M_j^{(1)\dagger} C^{(1)}_{\alpha \alpha'} C^{(M)}_{\alpha},
\]

(63)

where the last line holds because operators \( C^{(1)}_{\alpha \alpha'} \) and \( M_j^{(1)} \) either commute or anticommute. Then

\[
\sum_j p_j \rho_j^{(M)} \alpha \alpha' = \text{Tr} [\rho C^{(1)}_{\alpha \alpha'} \frac{N}{N} C^{(M)}_{\alpha}] = \frac{N-M}{N} \rho_{\alpha \alpha'},
\]

(65)

\( \forall \alpha, \alpha' \), implying \( \sum_j p_j \rho_j^{(M)} = \frac{N-M}{N} \rho^{(M)} \) and hence

\[
\rho^{(M)}/(N-1) M = \sum_j p_j \rho_j^{(M)}/(N-1) M,
\]

(66)

for the normalized \( M \)-body densities, i.e.,

\[
\rho_n^{(M)} = \sum_j p_j \rho_j^{(M)}.
\]

(67)

This equation implies the majorization relation (57) since

\[
\lambda(\sum_i A_i) < \sum_i \lambda(A_i),
\]

(68)

for any set of hermitian matrices \( A_i \) of the same dimension.

In (33) we have shown that one-body entanglement, i.e., the one quantified by the mixedness of the SPDM \( \rho^{(1)} \), is also non increasing under measurements of the occupancy of a fixed sp state. Such measurement, with just two-possible outcomes (1 or 0), is described by the number conserving projection operators \( \mathcal{P}_j = c_j^\dagger c_j \), \( \mathcal{P}_j = c_j^\dagger c_j = 1 - \mathcal{P}_j \) and leads to the majorization relation (32)

\[
\lambda(\rho^{(1)}) < n_j \lambda(\rho^{(1)}_j) + (1-n_j) \lambda(\rho^{(1)}_{\bar{j}}),
\]

(69)

between the spectra of the initial and post-selected SPDMs, where \( n_j = (\langle \Psi | c_j^\dagger c_j | \Psi \rangle) \) and \( \rho^{(1)}_j, \rho^{(1)}_{\bar{j}} \) are the SPDM’s determined by the post-selected states \( |\Psi_j\rangle = c_j^\dagger c_j |\Psi\rangle / \sqrt{n_j} \) and \( |\Psi_{\bar{j}}\rangle = c_j^\dagger c_j |\Psi\rangle / \sqrt{1-n_j} \). For an \( N \)-fermion state \( |\Psi\rangle \) an identical relation obviously holds for the normalized DMs \( \rho_n^{(1)} = \rho^{(1)}/N, \rho_n^{(1)} = \rho^{(1)}/N \).

However, Eq. (69) does not hold, in general, for \( \rho^{(M)} \) with \( M \geq 2 \), implying that \( M \)-body entanglement will not necessarily decrease after such measurement. A simple analytic example is provided in Appendix B. Essentially, measurement of the occupancy of a sp state reduces the available sp space for “collective pairs” in a state like (36), implying a lower maximum eigenvalue \( \lambda_1^{(M)} \) in the post-measurement states and hence violation of the inequality (69) by \( \rho^{(M)} \) with \( M \geq 2 \). This result is expected as these measurements do not necessarily increase our knowledge of the \( M \)-body DM for \( M \geq 2 \).

D. \( M \)-body density operators and generalized majorization relations

To each \( M \)-body DM we can associate an \( M \)-body density operator (DO)

\[
\hat{\rho}^{(M)} = \sum_{\alpha} \rho^{(M)}_{\alpha \alpha'} C^{(M)}_{\alpha} |0\rangle \langle 0| C^{(M)}_{\alpha'},
\]

(70)
which is the unique mixed state of $M$ fermions satisfying
\[ \text{Tr} \left[ \rho^{(M)}_{\alpha\alpha'} C^{(M)}_{\alpha} \right] = \delta_{\alpha\alpha'} \quad (71) \]
for all $\alpha, \alpha'$. Due to Eq. $(2)$. The normal decomposition $(23)$–$(30)$ provides its diagonal representation:
\[ \rho^{(M)} = \sum_{\nu} \lambda_{\nu}^{(M)} A^{(M)}_{\nu} |0\rangle \langle 0 | A^{(M)}_{\nu}^{\dagger} \] (72)

Now consider again the measurement $(36)$ applied on a general mixed state $\rho$ of $N$ fermions. If the result is unknown, the post-measurement state (without post-selection) $\rho' = \sum_{j} p_{j} \rho_{j}$ is the $N-1$ fermion state
\[ \rho' = \sum_{j} M_{j}^{(1)} \rho M_{j}^{(1)} \dagger \quad = \frac{1}{N} \sum_{j} c_{j} \rho_{j} \] (73)
Using Eq. $(65)$ for $M = N - 1$ we obtain
\[ \text{Tr} \left[ \rho' C^{(N-1)}_{\alpha} C^{(N-1)}_{\alpha'} \right] = \frac{1}{N} \rho^{(N-1)}_{\alpha\alpha'} \quad (74) \]
for all $\alpha, \alpha'$, implying $\rho' = \rho^{(N-1)}_{\alpha} / N$, the normalized $(N-1)$-body DO $\text{Tr} \rho^{(N-1)} = 1$. In summary,
\[ \rho^{(N-1)} = \sum_{j} c_{j} \rho_{j} \] (75)
The $(N-1)$-body DO is then just proportional to the post-measurement state $(73)$, with the operation in $(75)$ playing the role of a partial trace. Expressions similar or equivalent to $(75)$ have been previously derived in refs. $(27)$, $(36)$, $(38)$, with $(38)$ discussing its extension to states with no fixed fermion number.

These results, together with Eqs. $(57)$–$(62)$, can be extended to $L$-body measurements, in which $L$ fermions are annihilated. Such measurement can be obtained by applying previous measurement $L$ times, i.e., by composing it with itself $L$ times, and is described by the Kraus operators
\[ M_{\beta}^{(L)} = \frac{C^{(L)}_{\beta}}{\sqrt{\binom{N}{L}}} = \frac{c_{\beta 1} \cdots c_{\beta L}}{\sqrt{\binom{N}{L}}} \] (76)
which, due to Eq. $(1)$ satisfy
\[ \sum_{\beta} M^{(L)\dagger}_{\beta} M^{(L)}_{\beta} = \frac{1}{L} \sum_{\beta} C^{(L)\dagger}_{\beta} C^{(L)}_{\beta} = 1_{N} \] (77)
within the subspace of $N$-fermion states. Then,
\[ \text{Tr} \sum_{\beta} C^{(L)\dagger}_{\beta} \rho C^{(L)}_{\beta} C^{(M)\dagger}_{\alpha} C^{(M)}_{\alpha} = \binom{N-M}{L} \rho^{(M)}_{\alpha\alpha'} \] (78)
for all $\alpha, \alpha'$ for $M \leq N - L$. Hence, for $L = N - M$ it implies
\[ \rho^{(M)} = \sum_{\beta} C^{(N-M)\dagger}_{\beta} \rho C^{(N-M)}_{\beta} \] (79)
which generalizes Eq. $(74)$. The sum in $(80)$ is the post-measurement state (without post-selection) of the $L=(N-M)$-fermion measurement $(70)$.

For general $L \leq N$, this measurement has $\binom{N}{L}$ distinct outcomes $\beta$, with probabilities
\[ p_{\beta} = \text{Tr} \rho C^{(L)\dagger}_{\beta} C^{(L)}_{\beta} = \rho^{(L)}_{\beta} / \binom{N}{L} \] (81)
satisfying $\sum_{\beta} p_{\beta} = 1$, and post-selected states
\[ \rho_{\beta} = p_{\beta}^{-1} C^{(L)\dagger}_{\beta} \rho C^{(L)}_{\beta} = \rho^{(L)}_{\beta} / \rho^{(L)}_{\beta} : \] (82)
which generalize Eqs. $(58)$–$(59)$. From Eq. $(78)$ we then obtain, for the ensuing conditional $M$-body DMs of elements $(\rho^{(M)}_{\alpha\alpha'}) = \text{Tr} \rho_{\beta} C^{(M)\dagger}_{\alpha} C^{(M)}_{\alpha'}$, the expression
\[ \sum_{\beta} p_{\beta} \rho^{(M)}_{\beta} = \frac{\binom{N-M}{L}}{\binom{N}{L}} \rho^{(M)} \] (83)
for $M \leq N - L$. Eq. $(83)$ is equivalent to
\[ \sum_{\beta} p_{\beta} \rho^{(M)}_{\beta} / \binom{N-M}{L} = \rho^{(M)} / \binom{N}{L} \] (84)
and hence to
\[ \rho^{(M)}_{\beta} = \sum_{\beta} p_{\beta} \rho^{(M)}_{\beta} \] (85)
for the normalized $M$-body DMs. Eq. $(85)$ then implies the general majorization relation
\[ \lambda(\rho^{(M)}_{\beta}) < \sum_{\beta} p_{\beta} \lambda(\rho^{(M)}_{\beta}) \] (86)
between the initial and post-measurement conditional normalized $M$-body DMs, which generalizes Eq. $(61)$ to the measurement described by the operators $(76)$. The associated entropies satisfy
\[ S_{f}(\rho^{(M)}_{\beta}) \geq \sum_{\beta} p_{\beta} S_{f}(\rho^{(M)}_{\beta}) \] (87)
For pure states this implies that the entanglement entropies $(61)$ will not increase, on average, after these measurements. The same occurs with the associated entanglement of formation for initial mixed states.

E. Mapping to bipartite systems

In the previous sections it was proposed to link the mixedness of either $\rho^{(M)}$ or $\rho^{(N-M)}$, as reduced DM’s of a given $N$-fermion state, to the amount of correlations between $M$-body and $N-M$-body observables on such state. In this section we will show this relation is operationally justified by the existence of a class of quantum maps converting states of indistinguishable fermions into
states of effectively distinguishable fermions, in such a way that entanglement in the target state is bounded by the entropy (51) of the normalized M-body DM.

Let $|\Psi\rangle$ be an N-fermion state with support in a sp subspace $\mathcal{H}$ of dimension $D \geq N$ and let $\mathcal{H}_A$ be a sp subspace of dimension $D_A \geq M$ orthogonal to $\mathcal{H}$, such that $(c_{i_A}, c_{j}) = (c_{i_A}, c_{j})^\dagger = 0$ for $i_A (j)$ labelling sp states in $\mathcal{H}_A (\mathcal{H})$ (entailing $(i_A | j) = (0 | c_{i_A} c_{j}^\dagger) = 0$ for $i_A, j$). They are of course subspaces of a complete sp space $\mathcal{H}_T$ such that $\mathcal{H} \oplus \mathcal{H}_A \subset \mathcal{H}_T$. Consider now a CPTP map $T^r_M$ described by Kraus operators

$$T^r = \frac{1}{\sqrt{(M)}} \sum_{\mu, \alpha} T^r_{\mu \alpha} C^{(M)}_\mu | C^{(M)}_\alpha ,$$

where $C^{(M)}_\mu = (c_{i_A}^\dagger, \ldots, c_{i_M A}^\dagger)$ creates M fermions in $\mathcal{H}_A$ while $C^{(M)}_\alpha$ annihilates M fermions in $\mathcal{H}$, and $T^r$ is a $(D_A^r) \times (D_A^r)$ matrix. Assuming $\mathcal{H}_A$ initially “empty” and the condition $\sum_r T^r T^r = 1$, they will satisfy

$$\sum_r T^r T^r = \frac{1}{\sqrt{(M)}} \sum_{\mu, \alpha, \alpha', r} T^r_{\mu \alpha} C^{(M)}_\mu | C^{(M)}_{\alpha'} \alpha C^{(M)}_{\alpha'} \alpha C^{(M)}_{\alpha} = \mathbb{I}_N$$

by virtue of Eq. (4), within the Fock space $\mathcal{F}_N(\mathcal{H})$ of N fermion states with support in $\mathcal{H}$. Its action on an N-fermion state $|\Psi\rangle \in \mathcal{F}_N(\mathcal{H})$ is, using Eqs. (8) and (12),

$$T^r |\Psi\rangle = \frac{1}{\sqrt{(M)}} \sum_{\mu, \alpha, \alpha', r} T^r_{\mu \alpha} C^{(M)}_\mu | C^{(M)}_{\alpha'} \alpha C^{(M)}_{\alpha'} \alpha C^{(M)}_{\alpha} | 0 \rangle$$

$$= \sum_n \Gamma^r_{\mu \beta} C^{(M)}_\mu | C^{(N-M)}_{\alpha} \alpha | 0 \rangle ,$$

where $\Gamma^r = T^r |\Gamma^{(M)} | \Gamma^{(M)} = 1$ due to Eq. (10).

As a direct consequence of expression (91) we can derive the following important result: If $\lambda(\rho_A^r)$ and $\lambda(\rho^{(M)}_n)$ denote again the eigenvalue vectors (sorted in decreasing order) of $\rho_A^r$ and $\rho^{(M)}_n = \rho^{(M)} / (N_M)$ respectively, then the following majorization relation holds:

$$\lambda(\rho^{(M)}_n) \prec \sum_r p_r \lambda(\rho_A^r) ,$$

where the vector of smaller dimension is assumed to be completed with zeros to match the dimensions.

**Proof.** From Eqs. (91) and (12) we obtain

$$p_r \rho_A^r = \frac{1}{(M)} T^r \Gamma^{(M)} \Gamma^{(M)} | T^r = T^r \rho^{(M)} | T^r .$$

We can also write

$$\rho^{(M)}_n = \sum_r \sqrt{\rho^{(M)}_n | T^r \rho^{(M)}_n |} = \sum_r p_r \lambda(\rho_A^r) ,$$

which implies, using again (68),

$$\lambda(\rho^{(M)}_n) \prec \sum_r \lambda \left( \sqrt{\rho^{(M)}_n | T^r \rho^{(M)}_n |} \right) = \sum_r p_r \lambda(\rho_A^r)$$

since the nonzero eigenvalues of $(\sqrt{\rho^{(M)}_n | T^r \rho^{(M)}_n |})$ are the same as those of $T^r \rho^{(M)}_n | T^r = p_r \rho_A^r$. \qed

In particular, Eq. (92) implies that the average bipartite entanglement entropy between $A$ and $B$ of the final states, defined by $\sum_r p_r E_f (|\Phi_{AB}\rangle)$ with $E_f (|\Phi_{AB}\rangle) = S_f (|\rho_A^\tau\rangle) = S_f (|\rho_B^\tau\rangle)$, will never exceed the M-body entropy (51), which provides, therefore, an upper bound to the generated bipartite entanglement:

$$E_f (|\Psi\rangle) = S_f (\rho^{(M)}_n) \geq \sum_r p_r S_f (\rho_A^r) .$$

A second immediate corollary of (92) is that we can derive a condition for the conversion of a pure N-fermion state $|\Psi\rangle$ into a bipartite state $|\Phi_{AB}\rangle$ of $M$ and $N - M$ fermions in orthogonal sp spaces, i.e., with $M$ fermions occupying sp states in $\mathcal{H}_A$, and $N - M$ fermions in $\mathcal{H}_A$.

The map is implemented with outcome $r$, we can look at the reduced state of the fermionic modes in $\mathcal{H}_A$ in the state $|\Phi_{AB}\rangle$ (which will contain $M$ fermions), $\rho_A^r = \text{Tr}_B (|\Phi_{AB}\rangle | \Phi_{AB}\rangle)$, such that $|\Phi_{AB}\rangle O_A |\Phi_{AB}\rangle = \text{Tr} \rho_A^r O_A$ for any number conserving operator $O_A$ depending just on operators $c_{i_A}^\dagger$, $c_{i_A}$ with support in $\mathcal{H}_A$. Using (59) we obtain $\rho_A^r = \sum_{\mu, \mu'} (\rho_A^r)_{\mu \mu'} C^{(M)}_\mu | 0 \rangle (0 | C^{(M)}_{\mu'})$ with

$$\rho_A^r = \Gamma^r \Gamma^{r^*} / p_r .$$

Similarly $\rho_B^r = \Gamma^T \Gamma^{r^*} / p_r$.
We have therefore identified a class of quantum maps that could be used to transform a pure state $|\Psi\rangle$ of $N$ indistinguishable fermions into another state $|\Phi_{AB}\rangle$ which contains a definite number of fermions in two orthogonal sp subspaces, such that $M$ fermions can be effectively “distinguished” from the remaining $N - M$ due the orthogonality (for instance, $M$ fermions confined in a spatial region well separated from that of the remaining $N - M$ fermions, or in orbitals orthogonal to those occupied in $|\Psi\rangle$). The conversion is such that the entanglement between these two sets of particles in the target state is bounded from above, on average, by the entanglement between these two sets of particles in the target state is bounded from above, on average, by the amount of correlations between the indistinguishable particles in $|\Psi\rangle$.

As a trivial example, consider a two-fermion state

$$|\Psi\rangle = \left(\alpha c_{1}^\dagger c_{2}^\dagger + \beta c_{3}^\dagger c_{4}^\dagger\right)|0\rangle. \quad (97)$$

As mentioned in [11] any two-fermion state with support in a sp subspace of dimension 4 (i.e., occupying just 4 sp levels) can be written in this way [11, 12, 20]. Its SPDM $\rho^{(1)}$ is diagonal in this basis, with $\langle c_{i}^\dagger c_{i}\rangle = \delta_{ij}f_i$ and $f_i = |\alpha|^2$ for $i = 1, 2$, $f_i = |\beta|^2$ for $i = 3, 4$ and $f_i = 0$ otherwise, such that its nonzero eigenvalues are $\lambda(\rho^{(1)}) = (|\alpha|^2, |\alpha|^2, |\beta|^2, |\beta|^2)$, with $|\alpha|^2 + |\beta|^2 = 1$. Consider now the simple map $T = \sum_{i} c_{i}^\dagger c_{i}$, where $c_i$ annihilates a fermion in $H_i (i = 1, \ldots, D)$ while $c_{i}^\dagger$ creates a fermion in $H_A$, initially empty (and of dimension $D_A \geq D$). Then $T^\dagger T = 1_2$ in $F_2(\mathcal{H})$ and

$$T|\Psi\rangle = \frac{1}{\sqrt{2}}\left[\alpha(c_{1}^\dagger c_{2}^\dagger - c_{2}^\dagger c_{1}^\dagger) + \beta(c_{3}^\dagger c_{4}^\dagger - c_{4}^\dagger c_{3}^\dagger)\right]|0\rangle \quad (98)$$

is a normalized two-fermion state with one fermion in $H_A$ and one in $H_c$. It leads to reduced states $\rho_{A}(B)$ with spectrum $\lambda(\rho_{A}(B)) = (|\alpha|^2, |\alpha|^2, |\beta|^2, |\beta|^2)/2$ identical to that of $\rho^{(1)}/2$, thus saturating the inequalities of the majorization relation (92). We note that even if $\beta = 0$, in which case $|\Psi\rangle$ is a SD, $T|\Psi\rangle$ is no longer a SD and has therefore non-zero one-body entanglement, in agreement with the result that bipartite entanglement with fixed fermion number or number parity at each side requires one-body entanglement [32].

In contrast, for $T^\dagger T = \sum_{r} c_{r}^\dagger c_{r}$, $r = 1, \ldots, D$, still $\sum_{r} T^\dagger T = 1_2$ in $F_2(\mathcal{H})$ but $T^\dagger |\Psi\rangle$ is either 0 or proportional to a state $c_{1}^\dagger c_{2}^\dagger |0\rangle$ with $c_{0}^\dagger |0\rangle \in \mathcal{H}$, and no direct $A - B$ entanglement is generated, thus trivially satisfying Eq. (92).

IV. CONCLUSIONS

We have examined a general bipartite-like representation and Schmidt decomposition of arbitrary $N$-fermion states, which expresses it in terms of general $M$- and $(N-M)$-fermion creation operators. It is directly connected to the reduced $M$ and $(N-M)$-body DMs, which share the same non-zero eigenvalues, formally resembling the standard case of distinguishable components. It naturally leads to the concept of $M$-body entanglement, determined by the mixedness of the $M$ or $(N-M)$-body DMs, which generalizes one-body entanglement and characterizes the correlations between $M$- and $(N-M)$-body operators. Such entanglement is of course independent of the choice of sp basis (it is not a mode-entanglement) and in fact also of the choice of $M$-fermion creation operators, as long as they satisfy Eqs. (26)–(27).

The full set of $M$-body DM’s $\rho^{(M)} (1 \leq M \leq N/2)$ provides a detailed characterization of the structure of correlated $N$-fermion states. We have explicitly seen that correlated states which look similar at the level of the one-body DM, can lead to very distinct $M$-body DMs, as in the case of the states (13) and (30). In the latter, emergence of bosonic-like features is signaled by the appearance of an eigenvalue larger than 1 in the $M$-body DM for $M \geq 2$. On the other hand, all SDs (i.e. all free- or independent-fermion states) lead to idempotent $M$-body DMs (i.e. with eigenvalues 1 or 0) $\forall M$. The eigenvalues of $\rho^{(M)}$ determine the average of $M$-body operators and its largest eigenvalue provides an upper bound to all averages $(A^{(M)}) A^{(M)}$ (Eq. (53)) determined by “collective” operators $A^{(M)}$ creating a normalized state of $M$ fermions.

Finally, we have investigated some operational implications of $M$-body entanglement. By demonstrating the majorization relation (77), we have shown that the entropy (71) of the normalized $M$-body DM will not increase (and will in general decrease) under single fermion measurements determined by the Kraus operators (56). This result can be extended to general $L$-fermion measurements based on the operators (76) (Eqs. (56)–(77)), which have the reduced $M$-body DMs as post-measurement states. Moreover, by proving the majorization relation (92), we have shown that that such $M$-body entropy also provides an upper bound to the average bipartite entanglement entropy between $M$ and $N - M$ effectively distinguishable fermions generated by the mapping determined by the operators (58). Present results then provide the basis for a general theory of many-body entanglement beyond anti-symmetrization in fermion systems.

Appendix A: Eigenvalues of $\rho^{(M)}$ in the states $|\Psi_{2k}\rangle$

We first derive here the eigenvalues of the first three $M$-body DM’s in the states $|\Psi_{2k}\rangle$. Since fermions are created in pairs $c_{2i-1}^\dagger c_{2i}^\dagger$ with equal probability, the elements of the one-body DM in these states are easily seen to be

$$
\langle \Psi_{2k}|c_i^\dagger c_j|\Psi_{2k}\rangle = \delta_{ij} N/D,
$$

(A1)

implying $\rho^{(1)} = \frac{N}{D} \mathbb{1}$. Thus, it is the maximally mixed SPDM compatible with the total fermion number $N$, being hence diagonal in any sp basis with a single $D$-fold degenerate eigenvalue $N/D$.

On the other hand, the elements of the two-body DM are blocked in two submatrices. The first one, comprising the contiguous pair creation operators $c_{2i-1}^\dagger c_{2i}^\dagger$ that form the operator $A^1$ of Eq. (32), has elements

$$
\langle \Psi_{2k}|c_{2i-1}^\dagger c_{2i}^\dagger|\Psi_{2k}\rangle = \alpha \delta_{ij} + \beta (1-\delta_{ij}),
$$

(A2)

where, using $k=N/2$ and assuming $D$ even,

$$
\alpha = \frac{D^2/2-1}{D}, \quad \beta = \frac{D^2/2-1}{D(D-2)}.
$$

Hence, since this $D \times D$ block is just $(\alpha-\beta) \mathbb{1} + M$, with $M$ a rank one matrix with all elements equal to $\beta$, it has just two distinct eigenvalues: a nondegenerate eigenvalue

$$
\lambda^{(2)}_{\text{max}} = \alpha + (\frac{D}{2} - 1)\beta = k(1-2(k-1)/D),
$$

(A3)

which is precisely that associated with the collective uniformly weighted pair creation operator $A^1$:

$$
\langle \Psi_{2k}|A^1 A|\Psi_{2k}\rangle = \lambda^{(2)}_{\text{max}},
$$

(A4)

and a $(D/2-1)$-fold degenerate smaller eigenvalue

$$
\lambda^{(2)}_{\text{rest}} = \alpha - \beta = \frac{4k(k-1)}{D(D-2)}.
$$

(A5)

The other block comprises the remaining $(D/2) - D$ pair creation operators $c_i^\dagger c_j^\dagger$ involving two distinct pairs and is directly diagonal, with elements $\frac{D^2/2-1}{D} = \lambda^{(2)}_{\text{rest}}$. Thus, the final result is one large nondegenerate eigenvalue $\lambda^{(2)}_{\text{max}} \geq 1$, plus $(D/2) - 1$ smaller identical eigenvalues $\lambda^{(2)}_{\text{rest}} < 1$, satisfying

$$
\lambda^{(2)}_{\text{max}} + \left(\frac{D}{2} - 1\right) \lambda^{(2)}_{\text{rest}} = \left(\frac{N}{2}\right).
$$

(A6)

The same procedure can be applied to determine the eigenvalues of the three-body DM $\rho^{(3)}$. For creation of three fermions with two of them in one of the contiguous pairs $(2i-1, 2i)$, we obtain

$$
\langle \Psi_{2k}|c_{2i-1}^\dagger c_{2i}^\dagger c_k^\dagger c_k c_{2i-1}|\Psi_{2k}\rangle = \delta_{jk} [\gamma \delta_{il} + \eta (1-\delta_{il})]
$$

(A7)

where $k \neq 2l, k \neq 2l-1, j \neq 2i, j \neq 2i-1$, and

$$
\gamma = \frac{D^2/2-3}{D^2}, \quad \eta = \frac{D^2/2-2}{D^2}.
$$

Hence, we obtain $D$ identical $(\frac{D}{2} - 1) \times (\frac{D}{2} - 1)$ blocks, each of which has a large non-degenerate eigenvalue

$$
\lambda^{(3)}_{\text{max}} = \gamma + (\frac{D}{2} - 2)\eta = \frac{2k(k-1)(1-2(k-1)/D)}{D^2}
$$

(A8)

$$
= \langle \Psi_{2k}|A^{(3)\dagger}_1 A^{(3)}_1|\Psi_{2k}\rangle,
$$

(A9)

where $A^{(3)\dagger}_1 = \frac{1}{\sqrt{D(D-2)(D-4)}} \sum_{i,j,k} c_i^\dagger c_{2i}^\dagger c_{2j}^\dagger$, and $D-2$ smaller identical eigenvalues

$$
\lambda^{(3)}_{\text{rest}} = \gamma - \eta = \frac{8k(k-1)(k-2)}{D(D-2)(D-4)},
$$

(A10)

associated to orthogonal operators $A^{(3)\dagger}_2$. On the other hand, remaining $(\frac{D}{3} - 1)$ triplets $c_i^\dagger c_j^\dagger c_k^\dagger$ belonging to distinct pairs lead to a diagonal block in $\rho^{(3)}$ with identical diagonal elements $\frac{D^2/2-3}{D^2} = \lambda^{(3)}_{\text{rest}}$. Therefore, there are $D$ eigenvalues equal to $\lambda^{(3)}_{\text{max}}$ plus $(\frac{D}{3} - D)$ eigenvalues equal to $\lambda^{(3)}_{\text{rest}}$, satisfying

$$
D\lambda^{(3)}_{\text{max}} + \left(\frac{D}{3} - D\right) \lambda^{(2)}_{\text{rest}} = \left(\frac{N}{3}\right).
$$

(A11)

It should be noticed that while $\lambda^{(3)}_{\text{rest}} \leq 1$, $\lambda^{(3)}_{\text{max}} \geq 1$ for $1 + \sqrt{D/2} \leq k \leq D/2$, reaching its maximum for $k \approx D/3$ for $D \geq 6$, where $\lambda^{(3)}_{\text{max}} \approx 2D/27$.

For obtaining the largest eigenvalue $\lambda^{(2m)}$ of the $M = 2m$-body DM algebraically, we may directly note that it will arise from a $(\frac{D}{m}) \times (\frac{D}{m})$ block containing products of $m$ distinct pairs $c_{2i-1}^\dagger c_{2i}^\dagger$ and $c_{2j} c_{2j-1}$. All elements $\langle \Psi_{2k}|c_{2i-1}^\dagger c_{2i}^\dagger c_{2j}^\dagger c_{2j-1}|\Psi_{2k}\rangle$ will be positive with all rows of this block having the same sum owing to symmetry. Its largest eigenvalue will then be equal to this sum (as verified in [A3]) for $m=1$ and is associated to the uniform eigenvector $\alpha (1, 1, \ldots, 1)$, i.e., to the collective operator $A^{(2m)\dagger} \propto (A^1)^m$, of Eq. (39), implying Eq. (42).

Appendix B: Behavior of $\rho^{(2)}$ under single mode occupancy measurement

We will now prove that in the states $|\Phi_k\rangle$, measurement of the occupancy of one sp mode through the operators $P_k = c_k c_k$ and $P_k^\dagger = c_k^\dagger c_k^\dagger$, will break the analogous of Eq. (69) for $\rho^{(2)}$. We will prove in fact that the largest eigenvalue $\lambda^{(2)}_{k}$ of $\rho^{(2)}$ is greater than that of $\rho^{(2)}_k$ and $\rho^{(2)}_k$, implying

$$
\lambda^{(2)}_{\text{max}} > p_k \lambda^{(2)}_{k} + (1-p_k) \lambda^{(2)}_{1k},
$$

(B1)
which breaks the first majorization inequality.

Proof: If sp state \( k \) is measured to be occupied, which will occur with probability \( p_k = N/D \), the associated contiguous pair \((k, k + 1)\) (\( k \) odd) or \((k - 1, k)\) (\( k \) even) becomes “freezed” and the maximum eigenvalue \( \lambda_{k_{\text{max}}}^{(2)} \) of the ensuing DM \( \hat{\rho}_k^{(2)} \) will arise from the remaining \( N - 2 \) fermions occupying the other \( D - 2 \) sp states. Consequently, using Eq. (A3) for \( D \to D - 2 \) and \( k = N/2 \to N/2 - 1 \),

\[
\lambda_{k_{\text{max}}}^{(2)} = \frac{N - 2}{2(D - 2)}(D + 2 - N) < \frac{N}{2D}(D + 2 - N) = \lambda_{\text{max}}^{(2)}
\]

where the inequality holds for \( N < D \). Similarly, if state \( k \) is found to be empty, a similar reasoning leads to

\[
\lambda_{k_{\text{max}}}^{(2)} = \frac{N}{2(D - 2)}(D - N) < \frac{N}{2D}(D + 2 - N) = \lambda_{\text{max}}^{(2)}
\]

where the inequality holds for \( N > D \). These two results imply Eq. (B1) and hence violation of the majorization relation similar to (B3) for \( M = 2 \). Analogous results can be obtained for \( M = 3 \) in the same states (B6).

For completeness, we also verify that for the measurement (B5) in the same states (B6), the first inequality

\[
\frac{\lambda_{\text{max}}^{(2)}}{N/2} \leq \sum_k \frac{p_k \lambda_{k_{\text{max}}}^{(2)}}{N/2(k+1)}, \tag{B2}
\]

in (B7) for the largest eigenvalues of the initial and post-measurement normalized two-body DMs, does hold: Using again Eq. (A3) for \( \lambda_{k_{\text{max}}}^{(2)} \) (with \( k = N/2 \)) and \( \lambda_{k_{\text{max}}}^{(2)} \) (with \( k = N/2 - 1 \) and \( D \to D - 2 \)), with \( p_k = \frac{|\psi_k|^2}{N} = \frac{1}{D} \), we obtain, in agreement with (B2),

\[
\frac{1}{D} \sum_k \frac{(N - 2)(D + 2 - N)}{2(D - 2)((N - 1)/2)} = \frac{(D + 2 - N)}{D(N - 1)} \geq \frac{(D + 2 - N)}{D(N - 1)} = \frac{\lambda_{\text{max}}^{(2)}}{N/2}.
