Case Report

Un-re-sheath-able Misaligned pCONus Device: Case Report of a Unique Complication

Krishna Prasad Bellam Premnath, Gigy Kuruttukulam, Anil Kumar Shivan

Department of Neurointerventions, Rajagiri Hospital, Kochi, Kerala, India

pCONus is a stent like endovascular device which aids in retention of coils within wide necked bifurcation aneurysms. It is retrievable even after complete deployment and is detached electrolytically. pCONus aided coiling of wide necked bifurcation aneurysms has a high technical success rate and a good safety profile. Different complications have been described in literature with the usage of pCONus. This case report describes a yet unreported complication of un-re-sheath-ability of a misaligned deployed pCONus device.

INTRODUCTION

Treatment of wide necked bifurcation aneurysms incorporating part of parent vessel has always been difficult.[1-5] pCONus device is an improvised stent made for coiling wide necked bifurcation aneurysms using the "waffle cone" technique.[2] Studies on pCONus-assisted coiling have demonstrated a high technical success and a desirable safety profile.[1,4] Various technical and long-term complications have been observed.[1,4,5] Technical complication of a un-re-sheath-able misaligned deployed pCONus device has never been described.

KEYWORDS: Aneurysm, endovascular coiling, pCONus device, waffle cone technique

CASE REPORT

A 64-year-old female came with complaints of sudden onset severe headache which had started 3 days earlier. There was no neurological deficit. Plain computed

tomography scan of the brain showed Fisher Grade 1 subarachnoid hemorrhage in the right Sylvian fissure. Digital subtraction angiography through a right femoral access showed a wide necked middle cerebral artery bifurcation aneurysm measuring 7.3 mm × 5.8 mm, neck measuring 4 mm [Figure 1]. A decision to treat the aneurysm endovascularly with pCONus device assistance was made after an interdisciplinary discussion. Under adequate heparinization, the right femoral angiographic sheath was exchanged over a wire for a 7 French long sheath, and a 0.070” 6F Neuron guiding catheter (Penumbra Inc, Alameda, California, USA) was placed coaxially with its tip in the upper cervical segment of the internal carotid artery. A Vasco 0.021” microcatheter (Balt, Montmorency, France) was placed through the guiding catheter with its tip in the center of the aneurysm. A 20 mm long pCONus device with 6 mm crown was delivered through the microcatheter, the crown was deployed within the aneurysm and the microcatheter was pulled back to place the crown at the base of the aneurysm covering the neck. Four tablets of 75 mg prasugrel were administered through a nasogastric tube at this point. The rest of the device was deployed in the middle cerebral artery by unsheathing it. After unsheathing the device, there was prolapse of one of the crown petals into the inferior division of middle cerebral artery [Figure 2]. Repeated attempts at re-sheathing the device with the aim to reposition it by two operators failed. It was decided to proceed with coiling of the aneurysm with this misaligned position of the pCONus device rather than retrieve the device in its deployed state. A Vasco 0.010” microcatheter (Balt, Montmorency, France) was used to intubate the aneurysm through the pCONus device, and the aneurysm was coiled progressively using multiple coils (a three-dimensional [3D] coil followed by soft coils) with frequent repositioning of prolapsing coil loops. After the aneurysm was near-totally filled and there was minimal residual filling, further coil loops prolapsed into the parent vessel relentlessly on repeated trying, and dislodged a loop of an already placed coil into the parent vessel. Further attempts were hence abandoned. After the procedure, there was the minimal residual filling of the aneurysm, and good flow in the middle cerebral artery and its branches [Figure 3]. Nonflow-limiting dissection was seen in the distal internal carotid artery. There was no clinical complication, and the patient was discharged 5 days after the procedure. The patient was kept on dual antiplatelets (prasugrel and aspirin) for 3 months and single antiplatelet (aspirin) thereafter.

Follow-up angiography done at 3 months showed minimal residual filling and stable aneurysm size. There was complete occlusion on follow up angiography performed 6 months later and the dissection in the internal carotid artery had healed without luminal compromise [Figure 4].

**DISCUSSION**

Wide necked bifurcation aneurysms have always posed a challenge for endovascular treatment. Various strategies available for endovascular treatment of
bifurcation aneurysms include coiling using 3D coils, balloon-assisted coiling using a single complaint or two balloons, stent-assisted coiling with two stents in Y or T configuration or single stent using “shelf” technique or waffle cone technique, barrel stent-assisted coiling, intraaneurysmal flow diversion using WEB device, and pCONus-assisted coiling.\[1,3,5-7\] TriSpan and PulseRider devices which are designed specifically for wide necked bifurcation aneurysms are not widely used.\[4\] 3D coils have their limitations if the aneurysm is shallow, where even their shape alone is not enough to prevent prolapse into the parent vessel.\[5\] Balloon- or stent-assisted techniques require cannulation of the efferent vessels from the neck region of the aneurysm which is many a time technically very challenging.\[1,5\] The technique of cannulating an efferent vessel by creating of loop in the aneurysm and straightening the loop either with the “wire anchor loop traction” method or using a balloon, stent or a coil for anchoring is hazardous due to traction forces exerted on the aneurysm wall, especially if ruptured.\[1,8-10\] Simultaneous placement of multiple devices and catheters as required in balloon- or stent-assisted coiling may cause hemodynamic compromise resulting in cerebrovascular events.\[5\] In addition, balloons have a propensity to cause dissection if overinflated and there is a possibility of coil prolapse on balloon deflation.\[5,11\] Placement of double balloon or double stents for coiling of wide-necked bifurcation aneurysms is laden with significant complication rates.\[11,12\]

Deployment of a stent with its distal end within an aneurysm instead of bridging the neck is called the “waffle cone technique” and has been successfully applied using Neuroform, Enterprise, and Solitaire AB stents.\[3,13-15\]

The pCONus device is a nitinol stent with distal radially flared four loops (petals) which are to be positioned at the base of the aneurysm and an additional six polyamide fibers at the distal diameter of the stent forming a barrier preventing coil prolapse into the parent vessels. The device is compatible with a 0.021″ microcatheter, is retrievable even after complete deployment, and is detached electrolytically. pCONus-assisted coiling is technically easier and superior to double stent-assisted coiling since there is no necessity to cannulate the efferent vessels and there is less intravascular metal placement.\[5\] There is, however, an argument that there may be a detrimental effect on the hemodynamics due to flow diversion toward the aneurysm.\[17,18\] A study on intraaneurysmal flow kinetics using DSA optical flow imaging after deployment of pCONus device has shown no adverse increase in aneurysmal flow; on the contrary, it has shown a minimal reduction.\[16\] An added advantage of the device is that, in the case of aneurysm regrowth, the petals still remain at the neck of the aneurysm and facilitate coil retention within the aneurysm.\[5\]

The usage of pCONus device for ruptured aneurysms requires dual antplatelets which might confer additional risk to the procedure, however, has been used successfully in multiple studies.\[1,4,5\] Thromboembolic complications, both transient (5%-20%) and permanent (2.5%-10.5%) have been documented in various studies.\[1,4,5,9,20\] Failed detachment of a pCONus device has been reported, where the device was retrieved without re-sheathing into the microcatheter resulting in a nonflow-limiting dissection.\[1\] Prolapse of a petal of the pCONus device can occur when the device sizing is improper (choosing smaller crown
size than appropriate), if the aneurysm is eccentric to the parent vessel, or if excessive traction is applied to the pCONus device after it is deployed at the aneurysm neck. The pCONus device is compatible and has been used with a 0.021” microcatheter. Un-re-sheath-ability of a deployed pCONus device is of serious concern in case the device is misaligned with one or more of its distal petals prolapsing into the parent vessels. In such cases, aneurysm can be coiled without an additional device if the first deployed 3D coil is supported within the aneurysm optimally by the device; if not, an additional balloon or a stent placed within the branch harboring the prolapsed petal can be used to support coil retention within the aneurysm. Metal coverage of pCONus of <5%[1] would not cause any difficulty in placement of an additional stent or a balloon, and there is a description of placement of two stents through a pCONus device for a successful treatment of a basilar artery aneurysm.[6] Removal of the misaligned pCONus device in its deployed state using gentle traction is another option, as has been described once in a case of failed detachment of the device by Fischer et al.,[1] but was not performed in this case fearing the risk of endothelial damage to the aneurysm neck and parent vessel which might result in a dissection, which in unfortunate circumstances could be flow limiting or occluding. Probably, the usage of a 0.027” inner diameter microcatheter is likely to avoid this complication. To the best of our knowledge, un-re-sheath-ability of a misaligned pCONus device has not been described yet in literature; and such a complication is of serious concern if the misaligned device does not support coil retention within the aneurysm.

Declaration of patient consent

The authors certify that they have obtained all appropriate patient consent forms. In the form the patient(s) has/have given his/her/their consent for his/her/their images and other clinical information to be reported in the journal. The patients understand that their names and initials will not be published and due efforts will be made to conceal their identity, but anonymity cannot be guaranteed.
