Abstract

Background: Acute fatty liver of pregnancy (AFLP) and hemolysis, elevated liver enzymes and low platelets (HELLP) syndrome are two uncommon disorders that mimic each other clinically, but are distinct pathophysiologically. This study aimed to compare maternal and neonatal outcomes between AFLP and HELLP syndrome.

Methods: This retrospective cohort study was performed at a tertiary referral center in Taiwan between June 2004 and April 2020. We used the Swansea Criteria to diagnose AFLP, and the Tennessee Classification System to diagnose HELLP syndrome. Maternal characteristics, laboratory data, complications, and neonatal outcomes were analyzed.

Results: During the study period, 21 women had AFLP and 80 women had HELLP syndrome. There was a higher rate of preeclampsia (95.0% versus 23.8%) in the HELLP syndrome group compared to the AFLP group. However, the AFLP group had more other maternal complications including jaundice (85.7% versus 13.8%), acute kidney injury (61.9% versus 15.0%), disseminated intravascular coagulopathy (66.7% versus 8.8%), and sepsis (47.6% versus 10.0%) compared to the HELLP syndrome group. Nevertheless, higher rates of small for gestational age neonates (57.1% versus 33.3%), neonatal respiratory distress syndrome (39.2% versus 8.3%) and neonatal sepsis (34.2% versus 12.5%) were noted in the HELLP syndrome group.

Conclusions: AFLP is associated with a higher rate of multiple organ dysfunction in mothers, whereas HELLP syndrome is associated with a higher rate of neonatal morbidity.

Background

Liver diseases during pregnancy occur in up to 3% of all pregnant women, and severe forms can cause maternal and perinatal morbidity and mortality. They can be categorized into pregnancy-related and pre-existing liver disorders, of which the former includes hyperemesis gravidarum, intrahepatic cholestasis of pregnancy, preeclampsia with or without severe features, acute fatty liver of pregnancy (AFLP), and hemolysis, elevated liver enzymes and low platelets (HELLP) syndrome.

AFLP and HELLP syndrome, two uncommon disorders that mimic each other clinically but are distinct pathophysiologically, often arise after the third trimester and contribute to half of acute liver failure during pregnancy. AFLP occurs in 1:7000-15,000 of pregnancies, compared to an incidence of 0.2-0.8% for HELLP syndrome. AFLP, defined as the microvesicular fatty infiltration of hepatocytes during pregnancy, was first described by Stander and Cadden in 1934. HELLP syndrome is the combination of hemolysis with microangiopathic blood smears, increased liver enzymes and low platelet counts, and was first termed by Weinstein in 1982. Although still unclear, most previous studies have indicated that the main causes of AFLP are deficiency of fetal long-chain 3-hydroxyacyl coenzyme A dehydrogenase (LCHAD) and defects in fatty acid metabolism during pregnancy. The cause of HELLP syndrome is
thought to be due to abnormal placentation and the subsequent release of factors resulting in placental hypoperfusion, ischemia and systemic microangiopathies.

AFLP and HELLP syndrome should be managed promptly, yet differentiating these two disorders in timely fashion is difficult as they share similar initial clinical presentations and mainly unspecified gastrointestinal discomfort. Most previous studies were review articles that reported maternal conditions of the two disorders individually\(^6-8\) and few studies have compared the two disorders simultaneously in a cohort study\(^9,10\). Since the differential diagnosis between AFLP and HELLP syndrome has not been clearly recognized, we conducted this study to compare the maternal and neonatal outcomes between AFLP and HELLP syndrome, and further discussed the two pregnancy-related liver disorders with regards to their clinical features and laboratory findings.

**Methods**

This retrospective cohort study of pregnant women with liver disorders was performed at Mackay Memorial Hospital, a tertiary referral center in Taiwan, from June 2004 to April 2020. Detailed data were collected from obstetric records and neonatal databases using International Classification of Diseases (the ninth and tenth revisions) diagnosis codes. This study was approved by Mackay Memorial Hospital Institutional Review Board (IRB no. 19MMHIS291e), which advised that formal ethical approval with informed consent was unnecessary, as this study constituted a retrospective study. All personal identifiers were anonymized prior to analysis.

Patients with viral hepatitis, autoimmune hepatitis, cholestasis of pregnancy, biliary tract disease and ischemic hepatitis due to postpartum hemorrhage were excluded. We used the Swansea Criteria\(^2\) to diagnose AFLP, and the Tennessee Classification System\(^11\) to diagnose HELLP syndrome (Table 1). AFLP was diagnosed if the patient met six or more of the features in the absence of another explanation. Complete HELLP syndrome was diagnosed if the patient met all of the three laboratory criteria in the absence of another explanation. Patients with one or two of these laboratory criteria were defined as having partial HELLP syndrome.
Table 1
The Swansea Criteria for diagnosis of AFLP and the Tennessee Classification System for diagnosis of HELLP syndrome

| Swansea Criteria | Tennessee Classification System |
|------------------|---------------------------------|
| Vomiting         | AST > 70 IU/L                   |
| Abdominal pain   |                                 |
| Polydipsia or polyuria |                       |
| Encephalopathy   | LDH > 600 IU/L                  |
| Hyperbilirubinemia (> 0.8 mg/dL) |             |
| Hypoglycemia (< 72 mg/dL) |                               |
| Hyperuricemia (> 5.7 mg/dL) | Platelet < 100,000/μL         |
| Leukocytosis (> 11x10⁶/mL) |                               |
| Impaired liver function (AST or ALT > 42 IU/L) | |
| Hyperammonemia (> 66 μg/dL) |                               |
| Impaired renal function (creatinine > 1.7 mg/dL) | |
| Coagulopathy (PT > 14 s or aPTT > 34 s) |                           |
| Ascites or bright liver on ultrasound scan |                       |
| Microvesicular steatosis on liver biopsy |                     |

AFLP: acute fatty liver of pregnancy; HELLP: hemolysis, elevated liver enzymes and low platelets; AST: aspartate transaminase; ALT: alanine aminotransferase; PT: prothrombin time; aPTT: activated partial thromboplastin time; LDH: lactate dehydrogenase.

Maternal characteristics, laboratory data, complications, and neonatal outcomes between the two disorders were analyzed. Chronic hypertension during pregnancy was diagnosed if hypertension (systolic blood pressure ≥ 140 mmHg and/or diastolic blood pressure ≥ 90 mmHg) was first detected at < 20 gestational weeks. Gestational hypertension was diagnosed if new-onset hypertension was detected at ≥ 20 gestational weeks without the presence of proteinuria. Preeclampsia was defined as gestational hypertension combined with proteinuria or new signs of end-organ dysfunction. Preeclampsia with severe features included systolic blood pressure ≥ 160 mmHg or diastolic blood pressure ≥ 110 mmHg, platelet count < 100,000/μL, aspartate transaminase (AST) or alanine aminotransferase (ALT) levels twice the normal concentration, creatinine > 1.1 mg/dL or twice the normal concentration, pulmonary edema, or the new-onset of cerebral or visual disturbances. Pulmonary edema was diagnosed according to clinical and radiological findings. Acute kidney injury (AKI) was defined as an increase in serum creatinine (1.5 times the normal baseline within 7 days or ≥ 0.3 mg/dL within 2 days) or oliguria (urine output < 0.5 mL/kg per hour for 6 hours). Disseminated intravascular coagulopathy (DIC) was
diagnosed if the women met three or more of the following criteria: thrombocytopenia (< 100,000/μL), hypofibrinogenemia (< 300 mg/dL), positive D-dimer level (> 40 μg/dL), and prolonged prothrombin time (> 14 seconds) and activated partial thromboplastin time (> 40 seconds). Postpartum hemorrhage was defined as a blood loss of more than 500 mL within 24 hours after delivery. Sepsis was diagnosed as infection with an acute increase of ≥ 2 Sequential Organ Failure Assessment points. Small for gestational age (SGA) was defined as a birth weight < 10th percentile, based on the national singleton birth weight percentiles in Taiwan. Intracranial hemorrhage was diagnosed by cranial ultrasound. Respiratory distress syndrome (RDS) and transient tachypnea of the newborn were differentiated by chest image, clinical presentation, and the use of surfactant therapy. Persistent pulmonary hypertension of the newborn was diagnosed by evaluating pre- and post-ductal oxygen saturation, chest image, arterial blood gas, and echocardiography.

Expeditious delivery was suggested once AFLP was diagnosed, whereas it was suggested if HELLP syndrome developed at ≥ 34 gestational weeks or earlier if there was maternal distress (such as AKI, DIC, eclampsia, and suspected placental abruption), rapidly worsening laboratory values, uncontrolled hypertension, or non-reassuring fetal conditions. A single course of antenatal betamethasone was administered to the women between 23 and 34 weeks of pregnancy to reduce neonatal RDS if the maternal condition allowed, followed by delivery at 24 to 48 hours later.

SPSS version 24.0 (IBM Corporation, Armonk, NY, USA) was used for statistical analyses. The Chi-square or Fisher’s exact test was used for categorical variables, and the Student’s t test or Mann-Whitney U test was used for continuous variables. In addition, regression analysis with an S-curve of birth weight against gestational age at delivery was plotted between the AFLP and HELLP syndrome groups. A P value < 0.05 was considered to be statistically significant.

Results

During the study period, 916 pregnant women were initially diagnosed with liver disorders, of whom 106 pregnant women met the Swansea Criteria or the Tennessee Classification System. After excluding cases with acute hepatitis B flare up (n=1), ischemic hepatitis due to postpartum hemorrhage (n=2), acute cholecystitis (n=1), and intrahepatic cholestasis of pregnancy (n=1), 21 women were diagnosed with AFLP and 80 with HELLP syndrome (including 18 with complete and 62 with partial HELLP syndrome) (Figure 1).

The maternal characteristics are shown in Table 2. The maternal body mass index (BMI) at delivery in the HELLP syndrome group (28.73 ± 5.13 kg/m²) was significantly higher than that in the AFLP group (24.36 ± 3.26 kg/m²) (P = 0.009). Both maternal systolic and diastolic blood pressure levels on admission were significantly higher in the HELLP syndrome group than in the AFLP group (P< 0.001). The rate of twin pregnancy in the AFLP group was significantly higher than that in the HELLP syndrome group (28.6% versus 5.0%, P = 0.005). There were no significant differences in maternal age, gravidity, parity, delivery age, and delivery method between the two groups.
Table 2
Maternal characteristics of the AFLP and HELLP syndrome groups

AFLP: acute fatty liver of pregnancy; HELLP: hemolysis, elevated liver enzymes and low platelets; SBP: systolic blood pressure; DBP: diastolic blood pressure.

aStudent's t test, results are presented as mean ± standard deviation.

bMann-Whitney U test, results are presented as median (interquartile range).

cChi-square of Fisher's exact test, results are presented as number (percentage).

*P < 0.05 was considered to be statistically significant.

Table 3 shows the maternal laboratory data of the two groups. The AFLP group had higher frequencies of hypoglycemia (85.0 versus 98.5 mg/dL, P < 0.001), hyperbilirubinemia (4.4 versus 0.9 mg/dL, P < 0.001), impaired liver function (AST: 257 versus 124 IU/L, P = 0.003; ALT: 316 versus 135 IU/L, P = 0.006), impaired renal function (creatinine: 1.80 versus 0.80 mg/dL, P < 0.001), and coagulopathy (prothrombin time: 14.10 versus 9.50 seconds, P < 0.001; activated partial thromboplastin time: 38.50 versus 27.90 seconds, P < 0.001; fibrinogen: 192.96 versus 408.06 mg/dL, P < 0.001) than the HELLP syndrome group. However, the HELLP syndrome group had a significantly lower platelet count (89 x 10^3/μL versus 174 x 10^3/μL, P < 0.001) than the AFLP group. No significant differences were noted in the levels of
hemoglobin, leucocytes, uric acid, ammonia, and lactate dehydrogenase between the two groups. Figure 2 shows hepatic echograms in which AFLP was characterized by increased hepatic echogenicity and obscured periportal vessels.

Table 3

<sup>a</sup>Student’s t test, results are presented as mean ± standard deviation.

<sup>b</sup>Mann-Whitney U test, results are presented as median (interquartile range).

*P < 0.05 was considered to be statistically significant.

Table 4 shows the maternal complications of the two groups. There were significantly higher rates of preeclampsia (95.0% versus 23.8%, P < 0.001) and preeclampsia with severe features (95.0% versus 4.8%,
\( P < 0.001 \) in the HELLP syndrome group compared to the AFLP group. Four patients in the HELLP syndrome group had severe features of preeclampsia but were normotensive, so they were not diagnosed as having preeclampsia. However, the AFLP group had more other complications including jaundice (85.7% versus 13.8%, \( P < 0.001 \)), AKI (61.9% versus 15.0%, \( P < 0.001 \)), DIC (66.7% versus 8.8%, \( P < 0.001 \)), and sepsis (47.6% versus 10.0%, \( P < 0.001 \)) than the HELLP syndrome group. There were no significant differences in rates of pulmonary edema, postpartum hemorrhage, gastrointestinal bleeding, wound hematoma, and placental abruption between the two groups. In addition, postpartum events, length of hospital stay, intensive care unit admission rate, need for blood transfusion or liver transplantation, and maternal mortality were not statistically different between the two groups. One patient with AFLP required a liver transplantation due to a rapid deterioration in liver function. In addition, one of the women died due to HELLP syndrome complicated by posterior reversible encephalopathy syndrome and intracranial hemorrhage.
### Table 4
Maternal complications in the AFLP and HELLP syndrome groups

| Complication                      | AFLP (n=21) | HELLP syndrome (n=80) | P    |
|-----------------------------------|-------------|-----------------------|------|
| Preeclampsia                      | 5 (23.8)    | 76 (95.0)             | < 0.001* |
| Preeclampsia with severe features | 1 (4.8)     | 76 (95.0)             | < 0.001* |

| Postpartum event                  | 1 (4.8)     | 10 (12.5)             | 0.451 |
| Length of hospitalization (days)  | 9 (7)       | 6 (5.75)              | 0.066 |
| ICU admission                     | 4 (19.0)    | 8 (10.0)              | 0.267 |
| Maternal death                    | 0 (0)       | 1 (1.3)               | > 0.99 |

AFLP: acute fatty liver of pregnancy; HELLP: hemolysis, elevated liver enzymes and low platelets; AKI: acute kidney injury; DIC: disseminated intravascular coagulopathy; PPH: postpartum hemorrhage; ICU: intensive care unit.

*Note:*

- **a**Mann-Whitney U test, results are presented as median (interquartile range).
- **b**Chi-square of Fisher’s exact test, results are presented as number (percentage).
- *P* < 0.05 was considered to be statistically significant.
The neonatal outcomes are shown in Table 5. The birth weight of the HELLP syndrome group was significantly lower than that of the AFLP group (1686.05 ± 735.10 versus 2235.54 ± 591.72 g, \( P = 0.001 \)). The rate of SGA neonates was significantly higher in the HELLP syndrome group (57.1% versus 33.3%, \( P = 0.031 \)). In addition, higher rates of RDS (39.2% versus 8.3%, \( P = 0.004 \)) and sepsis (34.2% versus 12.5%, \( P = 0.041 \)) were noted in the HELLP syndrome group. There were no significant differences in birth age, Apgar scores, sex, stillbirth, intracranial hemorrhage, transient tachypnea of the newborn, persistent pulmonary hypertension of the newborn, neonatal intensive care unit admission rate, and neonatal mortality between the two groups. Six neonates died in the HELLP syndrome group, of whom five were due to prematurity, and one was due to sepsis.

An S-curve regression model was used to analyze birth weight against gestational age at delivery between the AFLP and HELLP syndrome groups, and the coefficients of determination (\( R^2 \)) were 0.836 and 0.582, respectively (Figure 3). It showed a gradual diverging trend of the two curves towards a higher birth weight in the AFLP group and lower birth weight in the HELLP syndrome group.
Table 5
Neonatal outcomes of the AFLP and HELLP syndrome groups

|                           | AFLP         | HELLP syndrome | P   |
|---------------------------|--------------|----------------|-----|
| Birth age (weeks)         | 34.57 (3.43) | 33.93 (6.86)   | 0.137 |
| Birth weight (g)          | 2235.54 ± 591.72 | 1686.05 ± 735.10 | 0.001* |
| Apgar score (1 min)       | 8 (5)        | 7 (3)          | 0.540 |
| Apgar score (5 min)       | 9 (3)        | 9 (1)          | 0.512 |
| Male                      | 17/27 (63.0) | 45/84 (53.0)   | 0.393 |
| SGA                       | 9/27 (33.3)  | 48/84 (57.1)   | 0.031* |
| Stillbirth                | 3/27 (11.1)  | 5/84 (6.0)     | 0.400 |

**Discussion**

AFLP: acute fatty liver of pregnancy; HELLP: hemolysis, elevated liver enzymes and low platelets; SGA: small for gestational age; ICH: intracranial hemorrhage; RDS: respiratory distress syndrome; TTN: transient tachypnea of the newborn; PPHN: persistent pulmonary hypertension of the newborn; NICU: neonatal intensive care unit.

*Student's t test, results are presented as mean ± standard deviation.

*Mann-Whitney U test, results are presented as median (interquartile range).

*Chi-square of Fisher's exact test, results are presented as number (percentage).
In this study, the women with AFLP were associated with hypoglycemia, hyperbilirubinemia, AKI, DIC and sepsis, whereas those with HELLP syndrome were associated with hypertension on admission, preeclampsia and low platelet counts. We also demonstrated a significantly higher rate of twin pregnancy in the AFLP group. However, more neonatal complications were noted in the HELLP syndrome group, such as SGA, RDS, and neonatal sepsis. Accordingly, clinical and laboratory evidence of hypoglycemia, hyperbilirubinemia, hypofibrinogenemia, AKI, DIC and sepsis may help to differentiate AFLP from HELLP syndrome.

AFLP and HELLP syndrome differed in the magnitude of systemic involvement. Multiple organ dysfunction was more likely to occur in the patients with AFLP. Hypoglycemia results from impaired hepatic glycogenolysis, and AFLP with hepatic steatosis can inhibit bilirubin clearance resulting in hyperbilirubinemia and jaundice\(^\text{19}\). AKI can be caused by defective renal fatty acid oxidation, and fatty degeneration in renal tubules\(^\text{20}\) while severe hepatic impairment can also lead to hepatorenal syndrome. The major cause of coagulopathy resulting in DIC is the reduction in hepatic production of fibrinogen and other procoagulant proteins\(^\text{19}\). Compared to the women with AFLP, those with HELLP syndrome had a higher BMI at delivery, which is consistent with previous studies that obesity is one of the risk factors of HELLP syndrome\(^\text{21}\).

Even with the various maternal complications associated with AFLP, neonatal morbidities in the AFLP group were not as high as those in the HELLP syndrome group. This may be because the toxic unoxidized fatty acids due to LCHAD deficiency in the AFLP group were transferred to the mother through the placenta instead of accumulating in the fetus, thereby not increasing neonatal morbidities compared to the HELLP syndrome group.

As would be anticipated, HELLP syndrome was more likely to occur in the patients with preeclampsia and a low platelet count. Although the relationship between HELLP syndrome and preeclampsia is still controversial, HELLP syndrome is usually considered to be a severe form or a variant of preeclampsia\(^\text{11}\). In addition, HELLP is related to endothelial injury and microangiopathic platelet consumption, which results in thrombocytopenia\(^\text{7}\).

Twin pregnancy has been reported to be a risk factor for both AFLP and HELLP syndrome\(^\text{9}\). However, in this head-to-head comparison study, the rate of twin pregnancy in the AFLP group was significantly higher than that in the HELLP syndrome group. Most previous studies have indicated that fetal LCHAD deficiency\(^\text{4}\) and other types of deficiencies in fetoplacental mitochondrial oxidation, such as short-chain acyl-coenzyme dehydrogenase deficiency and carnitine palmitoyltransferase deficiency are related to the development of AFLP\(^\text{22,23}\). Accordingly, it has been hypothesized that twice the amount of upstream metabolites accumulate in the circulation of mothers with twins due to these enzyme deficiencies, resulting in a lower threshold to express clinical symptoms and signs in patients with AFLP.

Another important finding of this study is the significantly higher rate of SGA neonates born to the mothers with HELLP syndrome. Although twin pregnancy is known to be a key factor leading to SGA, we
found a higher rate of twin pregnancy in the AFLP group rather than the HELLP syndrome group. This could be explained by the abnormal placentation in patients with HELLP syndrome. Alterations in platelet activation, increases in pro-inflammatory cytokines, and segmental vasospasm with vascular endothelial damage could impair nutritional exchange through the feto-placental unit and subsequently result in SGA\(^3,5\). In addition, higher rates of neonatal RDS and sepsis were also noted in the HELLP syndrome group. A correlation between SGA and RDS has been reported, possibly because intrauterine lung development can be adversely affected by SGA due to reduced substrate supply, fetal hypoxemia and hypercortisolism\(^24\). The possible mechanism of increased sepsis in SGA neonates is the delayed immune system development, which results in a higher rate of neonatal infection\(^25\).

The strengths of this study include that this was a head-to-head comparison study of both maternal and neonatal outcomes. Moreover, the data were collected from one medical center, which could minimize management bias in different institutions. Nevertheless, there are several limitations to this study. First, the data were collected from one medical center, and thus the case numbers were limited even a near 17-year span. Second, advances in maternal and neonatal care in the recent two decades may have resulted in different maternal and neonatal outcomes.

**Conclusions**

Both AFLP and HELLP syndrome affect liver function yet differ in the magnitude of systemic involvement. Multiple organ dysfunction was more likely to occur in the patients with AFLP. However, more neonatal morbidities were noted in the HELLP syndrome group. These results may help us to differentiate between the two pregnancy-related liver disorders, and when explaining the management and prognosis during shared decision making with patients.

**Declarations**

**Ethics approval and consent to participate:**

This study was approved by Mackay Memorial Hospital Institutional Review Board (IRB no. 19MMHIS291e), which advised that formal ethical approval with informed consent was unnecessary, as this study constituted a retrospective study. All personal identifiers were anonymized prior to analysis.

**Consent for publication:**

Not applicable

**Availability of data and materials:**
The datasets used and/or analysed during the current study are available from the corresponding author on reasonable request

**Competing interests:**

The authors declare that they have no competing interests

**Funding:**

The authors declare that they have no funding for the research

**Authors’ contributions:**

SX Ang is the first author who collects data and composes the main part of this article. FJ Sun provides professional guide on statistical analysis while CP Chen and CY Chen are in charge of the final review and amendment. All authors read and approved the final manuscript.

**Acknowledgements:**
