(Dated: March 27, 2022)

To support the validity of a factorizable metric ansatz used in string cosmology, we investigate a toy problem in RSI model. For this purpose, we revise the gradient expansion method to conform to the factorizable metric ansatz. By solving the 5-dimensional equations of motion and substituting the results into the action, we obtain the 4-dimensional effective action. It turns out that the resultant action is equivalent to that obtained by assuming the factorizable metric ansatz. Our analysis gives the support of the validity of the factorizable metric ansatz.

I. INTRODUCTION

Results from WMAP strongly support the idea of the inflationary universe. Hence, it is an urgent matter to construct an inflaton potential that agrees with observations based on the fundamental theory such as the string theory. Recent intense researches on inflationary models in string theory have stemmed from the success to construct brane inflation with moduli stabilization [1]. However, almost all studies computing potentials for moduli ansatz for the metric is crucial in the discussion of the validity near each one of the branes. As this factorizable ansatz is challenged by de Alwis [3]. In order to investigate the validity of this ansatz, we present our strategy to attack the issue. In Sec.III, we solve the bulk equations of motion using the revised gradient expansion method. In the Sec.IV, we derive the 4-dimensional effective action and discuss the validity of the factorizable metric ansatz. The final section is devoted to the conclusion.

II. HOW TO JUSTIFY THE METRIC ANSATZ?

We consider an $S_1/Z_2$ orbifold spacetime with the two branes as the fixed points. In the RSI model, the two flat 3-branes are embedded in the 5-dimensional asymptotically anti-deSitter (AdS) bulk with the curvature radius $\ell$ and brane tensions given by $\sigma_+ = 6/(\kappa^2 \ell)$ and $\sigma_- = -6/(\kappa^2 \ell)$. The model is described by the action

$$ S = \frac{1}{2\kappa^2} \int d^3 x \sqrt{-G} \left[ R + \frac{12}{\ell^2} \right] - \frac{6}{\kappa^2 \ell} \int d^4 x \sqrt{-g} + \frac{6}{\kappa^2 \ell} \int d^4 x \sqrt{-g_-} + \frac{2}{\kappa^2} \int d^4 x \sqrt{-g_+ \mathcal{K}_+} - \frac{2}{\kappa^2} \int d^4 x \sqrt{-g_- \mathcal{K}_-} \tag{5} $$

where $\mathcal{K}_\pm$ is the trace part of the extrinsic curvature of the boundary near each one of the branes.

Here, the question is how to obtain the effective action for discussing the cosmology. One often takes the metric

$$ ds^2 = a^2(y)g_{\mu\nu}(x)dx^\mu dx^\nu + \mathcal{G}_{yy}(x)dy^2, \tag{4} $$

with a spacetime dependent metric $g_{\mu\nu}(x)$ as

$$ ds^2 = a^2(y)\eta_{\mu\nu}dx^\mu dx^\nu + dy^2, \quad a(y) = e^{-y/\ell} \tag{3} $$

where we also included the modulus field $\mathcal{G}_{yy}$. The question is the validity of this assumption in the context of the brane cosmology. In this paper, we derive the four dimensional low energy effective action on the brane without using this ansatz. Then, we compare the result with the effective action derived using the factorizable ansatz to examine its validity.
ansatz and substitutes the ansatz into the action to get the 4-dimensional effective action. Let us assume that the metric is factorizable
\[ ds^2 = a^2(y)g_{\mu\nu}(x)dx^\mu dx^\nu + G_{yy}(x)dy^2 \] (6)
and the branes are located at the fixed coordinate points. Substituting this metric into the action and integrating out the result with respect to \( y \), we obtain the 4-dimensional action. However, an inadequate restriction of the functional space in the variational problem yields the wrong result. The correct procedure to obtain the 4-dimensional effective action is first to solve the bulk equations of motion and substitute the results into the original action. To solve the bulk equations, we employ the gradient expansion method. Our analysis using the gradient expansion method shows that the correct metric takes the form
\[ ds^2 = a^2(y)\sqrt{G_{yy}(x)}g_{\mu\nu}(x)dx^\mu dx^\nu + G_{yy}(x)dy^2 \] (7)
which clearly reject the factorizable ansatz.

However, there is another possibility. One can assume the following factorizable metric
\[ ds^2 = a^2(y)g_{\mu\nu}(x)dx^\mu dx^\nu + dy^2 \] (8)
and the branes are moving in the above coordinates. Namely, the positive and negative tension branes are respectively placed at
\[ y = \phi_+(x), \quad y = \phi_-(x) \] (9)
which are often referred to as the moduli fields. This is another description of the RSI cosmology and often called as moduli approximation in the literature. Although two scalar fields are introduced, one of which is the extra degree of freedom as we will see later in Eq. The physical quantity is the difference of these moduli fields which corresponds to the radion in our previous work. This ansatz leads to the action
\[ S = \frac{\ell}{2\kappa^2} \int d^4x \sqrt{-\gamma} \left\{ a^2(\phi_+) - a^2(\phi_-) \right\} R(g) + \frac{6}{\ell^2} \left\{ a^2(\phi_+)(\partial\phi_+)^2 - a^2(\phi_-)(\partial\phi_-)^2 \right\} \] (10)
In this case, we do not have the result to be compared, because the gradient expansion method is not prepared for this parameterization of the model. Our aim is to examine the validity of this ansatz by conforming the gradient expansion method to the factorizable metric ansatz.

III. REVISED GRADIENT EXPANSION METHOD

The metric we take in solving the bulk equations of motion is the one in the Gaussian normal coordinate system
\[ ds^2 = \gamma_{\mu\nu}(y,x)dx^\mu dx^\nu + dy^2 \] (11)
where the factorized metric is not assumed.

Now we give the basic equations in the bulk. When solving the bulk equations of motion, it is convenient to define the extrinsic curvature on the \( y = \text{constant} \) slicing as \( K_{\mu\nu} = -\frac{1}{2}\partial_y \gamma_{\mu\nu} \). Decomposing this extrinsic curvature into the traceless part and the trace part
\[ K_{\mu\nu} = \Sigma_{\mu\nu} + \frac{1}{4}\gamma_{\mu\nu}K, \quad K = -\frac{\partial}{\partial y} \log \sqrt{-\gamma} \] (12)
we obtain the basic equations which hold in the bulk;
\[ \Sigma^{\mu\nu} - K\Sigma^{\mu\nu} = - \left[ R^{\mu\nu}(\gamma) - \frac{1}{4}\delta^{\mu\nu}R(\gamma) \right] \] (13)
\[ \frac{3}{4}K^2 - \Sigma^{\alpha\beta}\Sigma_{\alpha\beta} = R(\gamma) + \frac{12}{\ell^2} \] (14)
\[ \nabla_\lambda \Sigma^{\mu\lambda} - \frac{3}{4}\nabla_\mu K = 0 \] (15)
where \( \nabla_\mu \) denotes the covariant derivative with respect to the metric \( \gamma_{\mu\nu} \) and \( R^{\mu\nu}(\gamma) \) is the corresponding curvature.

The effective action have to be derived by substituting the solution of Eqs. (13) into the action and integrating over the bulk coordinate \( y \). In reality, it is difficult to perform this general procedure. However, what we need is the low energy effective theory. At low energy, the energy density of the matter, \( \rho \), on a brane is smaller than the brane tension, i.e., \( \rho/|\sigma| \ll 1 \). In this regime, the 4-dimensional curvature can be neglected compared with the extrinsic curvature. Thus, the Anti-Newtonian or gradient expansion method used in the cosmological context is applicable to our problem.

A. Zeroth Order

At zeroth order, we can neglect the curvature term in Eqs. (13)~(15). Moreover, the tension term only induces the isotropic bending of the brane. Thus, an anisotropic term vanishes at this order, \( \Sigma^{\mu\nu} = 0 \). As the result, we obtain
\[ \frac{\partial (\gamma_{\mu\nu})}{\ell} \quad \text{or} \quad \gamma_{\mu\nu} = \frac{1}{\ell^2} \delta^{\mu\nu} \] (16)
Using the definition of the extrinsic curvature
\[ K^{(0)} = \frac{4}{\ell} \quad \text{or} \quad K^{(0)}_{\mu\nu} = \frac{1}{\ell^2} \delta^{\mu\nu} \] (17)
we get the zeroth order metric as
\[ ds^2 = dy^2 + a^2(y)g_{\mu\nu}(x)dx^\mu dx^\nu, \quad a(y) = e^{-y/\ell} \] (18)
where the tensor \( g_{\mu\nu} \) is the constant of integration which weakly depends on the brane coordinates \( x^\mu \).
B. First Order

Our iteration scheme is to write the metric $\gamma_{\mu\nu}$ as a sum of local tensors built out of $g_{\mu\nu}$, with the number of derivatives increasing with the order of iteration, that is, $O((\ell/L)^n)$, $n = 0, 1, 2, \ldots$. Here, $L$ represents the characteristic length scale of the 4-dimensional curvature. Hence, we seek the metric as a perturbative series

$$\gamma_{\mu\nu}(y, x) = a^2(y) [g_{\mu\nu}(x) + f_{\mu\nu}(y, x) + \cdots] . \quad (19)$$

The effective action can be constructed with the knowledge of the leading order metric $f_{\mu\nu}(y, x)$. Other quantities can be also expanded as

$$K^\mu_\nu = \frac{1}{\ell} \delta^\mu_\nu + \frac{1}{\ell} \Sigma^\mu_\nu + \cdots ,$$

$$\Sigma^\mu_\nu = 0 + \frac{1}{\ell} \delta^\mu_\nu + \cdots . \quad (20)$$

The first order solutions are obtained by taking into account the terms neglected at zeroth order. At first order, Eqs. (13) – (15) become

$$(1) \Sigma_{\mu\nu, y} = -\left[ R_{\mu\nu}(\gamma) - \frac{1}{4} \delta^\mu_\nu R(\gamma) \right] , \quad (21)$$

$$\frac{6}{\ell} (1) K = \left[ R(\gamma) \right] , \quad (22)$$

$$(1) \Sigma^\mu_\nu + \lambda \frac{3}{4} (1) K = 0 . \quad (23)$$

where the superscript (1) represents the order of the derivative expansion and $|$ denotes the covariant derivative with respect to the metric $g_{\mu\nu}$. Here, $[R_{\mu\nu}(\gamma)]$ means that the curvature is approximated by taking the Ricci tensor of $a^2(y)g_{\mu\nu}(x)$ in place of $R_{\mu\nu}(\gamma)$. It is also convenient to write it in terms of the Ricci tensor of $g_{\mu\nu}$, denoted by $R_{\mu\nu}(g)$.

Substituting the zeroth order metric into $R(\gamma)$, we can write Eq. (22) as

$$\frac{1}{\ell} K = \frac{\ell}{6a^2} R(g) . \quad (24)$$

Hereafter, we omit the argument of the curvature for simplicity. Simple integration of Eq. (21) also gives the traceless part of the extrinsic curvature as

$$(1) \Sigma^\mu_\nu = \frac{\ell}{2a^2} \left( R_{\mu\nu} - \frac{1}{4} \delta^\mu_\nu R \right) + \frac{\chi^\mu_\nu(x)}{a^4} , \quad (25)$$

where $\chi^\mu_\nu$ is the constant of integration which satisfies

$$\chi^\mu_\mu = 0 , \quad \chi^\mu_{\nu|\mu} = 0 . \quad (26)$$

Here, the latter condition came from Eq. (24). In our previous work [2, 3], we find this term corresponds to the dark radiation at this order. Due to the traceless property, $\chi^\mu_\nu$ is not relevant to the derivation of the effective action.

From Eqs. (21) and (25), the correction to the metric $g_{\mu\nu}$ at this order can be obtained as

$$f_{\mu\nu}(y, x) = -\frac{\ell^2}{2a^2} \left( R_{\mu\nu} - \frac{1}{6} g_{\mu\nu} R \right) - \frac{\ell^2}{2a^2} \chi_{\mu\nu} + C_{\mu\nu}(x) , \quad (27)$$

where $C_{\mu\nu}$ is the constant of integration which will be fixed later in Eq. (15).

IV. EFFECTIVE ACTION

Now, up to the first order, we have

$$g_{\mu\nu}(y, x) = a^2(y) [g_{\mu\nu}(x) + f_{\mu\nu}(y, x)] . \quad (28)$$

In the following, we will calculate the bulk action, $S_{\text{bulk}}$, the actions for each brane, $S_{\pm}$ and the Gibbons-Hawking term, $S_{\text{GH}}$, separately. After that, we collect all of them and obtain the 4-dimensional effective action.

In order to calculate the bulk action, we need the determinant of the induced metric on each brane. The induced metric on each brane is written by

$$g_{\mu\nu}(\phi_{\pm}, x) = a^2 g_{\mu\nu}(x) + a^2 f_{\mu\nu}(\phi_{\pm}, x) + \partial_\mu \phi_{\pm} \partial_\nu \phi_{\pm} . \quad (31)$$

The determinant of the induced metric can be calculated as

$$\sqrt{-g_{\pm}} = a^4 (\phi_{\pm}) \sqrt{-g} \left[ 1 + \frac{1}{a^4} (\partial \phi_{\pm})^2 - \frac{\ell}{6a^2} R + C_{\mu\nu} \right] \left[ 1 + \frac{C_{\mu\nu}}{2} \right] , \quad (32)$$

where we have used the equation $R = -20/\ell^2$ which holds in the bulk. Notice that the Ricci scalar came from $\text{tr} f_{\mu\nu}$ in $\sqrt{-g}$. Next, let us calculate the action for the brane tension. The induced metric on each brane is written by

$$g_{\mu\nu}(\phi_{\pm}, x) = a^2 g_{\mu\nu}(x) + a^2 f_{\mu\nu}(\phi_{\pm}, x) + \partial_\mu \phi_{\pm} \partial_\nu \phi_{\pm} \quad (31)$$

The determinant of the induced metric can be calculated as

$$\sqrt{-g_{\pm}} = a^4 (\phi_{\pm}) \sqrt{-g} \left[ 1 + \frac{1}{a^4} (\partial \phi_{\pm})^2 - \frac{\ell}{6a^2} R + C_{\mu\nu} \right] \left[ 1 + \frac{C_{\mu\nu}}{2} \right] , \quad (32)$$

where $C_{\mu\nu}$ is the constant of integration which will be fixed later in Eq. (15).
where \((\partial \phi_\pm)^2\) means \(\partial^\mu \phi_\pm \partial_\mu \phi_\pm\). Thus, the action for each brane becomes

\[
S_\pm = \mp \frac{6}{\kappa^2 \ell} \int d^4x \sqrt{-g_\pm} \frac{1}{\ell} \left[ a^2(\phi_\pm) + \frac{a^2(\phi_\pm) (\partial \phi_\pm)^2}{4} \right] + \frac{\ell}{2} a^2(\phi_\pm) R \left[ 1 + \frac{C_\mu^\mu}{2} \right].
\]

Note that the Ricci scalar came from \(\text{tr} f_{\mu\nu} \), \(\sqrt{-g_\pm}\), and \(\text{tr} f_{\mu\nu,\gamma} \) into the 5-dimensional action Eq. (33). We get the 4-dimensional effective action

\[
S = S_{\text{bulk}} + S_+ + S_- + S_{\text{GH}}
\]

\[
= \frac{\ell}{2\kappa^2} \int d^4x \sqrt{-g} \left[ \left\{ a^2(\phi_+) - a^2(\phi_-) \right\} R + \frac{6}{\ell^2} \left\{ a^2(\phi_+) (\partial \phi_+)^2 - a^2(\phi_-) (\partial \phi_-)^2 \right\} \right] \times \left[ 1 + \frac{C_\mu^\mu}{2} \right].
\]

Note that the Ricci scalar came from \(\text{tr} f_{\mu\nu} \) in \(\sqrt{-g_\pm}\), \(\text{tr} f_{\mu\nu,\gamma} \) in \(K_\pm\).

To support the validity of the factorizable metric ansatz used in string cosmology, we investigated a toy
problem in RSI model. For this purpose, we have revised the gradient expansion method to conform to the the factorizable metric ansatz. We have solved the 5-dimensional equations of motion and substituted the results into the action. Consequently, we have obtained the 4-dimensional effective action which is equivalent to that obtained by assuming the factorizable metric ansatz. Hence, our calculation supports the factorizable metric ansatz.

In the higher order analysis including Kaluza-Klein corrections, the factorizable metric ansatz cannot be correct anymore. However, in string cosmology, what we want is the leading order action. Then the factorizable metric ansatz becomes useful method when discussing the cosmology without solving the bulk equations of motion at least at the leading order.

Finally, we should mention the limitation of our approach. Although we have shown the validity of the factorizable ansatz in 5-dimensions, the issue is still unclear in the case of higher codimension. This is because the higher codimension objects is difficult to treat in a relativistic manner. To give a more strong support of the factorizable metric ansatz, we need to settle this issue.
