Abstract
We explore the possibility of generating large-scale magnetic fields from second-order cosmological perturbations during the pre-recombination era. The key process for this is Thomson scattering between the photons and the charged particles within the cosmic plasma. To tame the multi-component interacting fluid system, we employ the tight coupling approximation. It is shown that the source term for the magnetic field is given by the vorticity, which signals the intrinsically second-order quantities, and the product of the first-order perturbations. The vorticity itself is sourced by the product of the first-order quantities in the vorticity evolution equation. The magnetic fields generated by this process are estimated to be \( \sim 10^{-29} \) G on the horizon scale at the recombination epoch. Although our rough estimate suggests that the current generation mechanism can work even on smaller scales, more careful investigation is needed to make clear whether it indeed works in a wide range of spatial scales.

PACS number: 98.80.–k

1. Introduction
Magnetic fields are known to be present on various scales in the universe [1]. For example, magnetic fields are observed in galaxies and clusters, with intensity \( \sim 1 \mu \)G. Only an upper limit has been given for magnetic fields on cosmological scales, \( < 10^{-9} \) G. Primordial large-scale magnetic fields may be present and serve as seeds for the magnetic fields in galaxies and clusters, which are amplified through the dynamo mechanism after galaxy formation. We
need numerical calculations in order to evaluate precisely a necessary seed magnetic field, however we can estimate order of magnitude of it and it is \( \sim 10^{-21} \) to \( 10^{-31} \) G at 100 Mpc [2]. If sufficiently large, the primordial magnetic field could leave observable imprints on the cosmic microwave background [3].

A number of models have been proposed for generating large-scale magnetic fields in the early universe [4–6]. However, they rely more or less on some unknown physics. In this paper, we discuss magnetogenesis in the pre-recombination era using only the conventional physics that has been established. The generation of magnetic fields in this era has been studied in [7–15]. Now it is widely accepted that large-scale cosmological perturbations, generated from inflation in the early universe, evolve into a variety of structures such as the cosmic microwave background anisotropies and galaxies. However, inflation produces only density fluctuations (scalar perturbations) and gravitational waves (tensor perturbations); vector perturbations, and hence large-scale magnetic fields, are not generated in the context of the usual inflationary scenarios, unless, for instance, modifying the Maxwell theory of electromagnetism. Even if they were generated due to some mechanism, they only decay without any sources. This no-go argument is based on linear perturbation theory and so we will be studying second-order perturbations to overcome this difficulty within inflation and the standard Maxwell theory. We consider a multi-fluid system composed of photons, electrons and protons, which are tightly coupled via Thomson and Coulomb scattering but slightly deviate from each other [16]. Thomson scattering is important for the generation of large-scale magnetic fields in the pre-recombination era, because a rotational current will be produced by the momentum transfer due to the Thomson interaction. We shall see how this process occurs by doing the tight coupling expansion.

The timescales of Thomson scattering, Coulomb scattering and the plasma oscillation at \( z \sim 10^5 \) are \( \tau_T = 10^3 \) s, \( \tau_C = 10^{-3} \) s and \( \omega_p^{-1} = 10^{-9} \) s, respectively [14]. The last two timescales are much smaller than the Thomson timescale, implying that the effects of Coulomb scattering and plasma oscillations are smoothed out within the Thomson timescale. For this reason, we will not take seriously Coulomb scattering and plasma oscillations [11, 14]. And the effect of the synthesis of hydrogen, i.e., the ionization rate, on magnetogenesis may be taken into account carefully [15]. It has been reported that the change of the ionization rate does not affect the generation of magnetic fields on cosmological scales, though the effect can no longer be ignored on scales smaller than AU. Thus, for our current purpose, it is safe to ignore the effect of the synthesis of hydrogen.

This paper is most closely related to the work of [11], which studied how magnetic fields are generated from nonlinear cosmic inhomogeneities using the tight coupling approximation. While the covariant formalism was used in [11], we use in this paper the cosmological perturbation theory and so the two works are complementary to each other. Recently, Takahashi et al took a simplified Newtonian approach to see the detailed physical processes that result in magnetogenesis in the pre-recombination era [14]. The present study may be viewed as the general relativistic extension of [14]. Second-order vector perturbations have also been studied previously in different contexts [17–20]. Although our rough estimate suggests that the current generation mechanism can work, more careful investigation is needed to make clear whether it indeed works in a wide range of spatial scales.

The organization of this paper is as follows. In the following section, we define our key quantities and derive the equations of motion based on second-order cosmological perturbation theory. In section 3, we invoke the tight coupling approximation to solve the relevant equations, giving a compact formula describing the generation of magnetic fields. In section 4, we give a summary of this paper.
2. Basic equations in second-order cosmological perturbation theory

2.1. The energy–momentum equations up to second-order in perturbation theory

We start with defining the metric and the energy–momentum tensor we use. Throughout the paper we rely on the energy–momentum (non)conservation equations and so we explicitly write them down in this section.

The background spacetime is given by the spatially flat Friedmann–Lemaître–Robertson–Walker metric. We write the perturbed metric in the Poisson gauge as

\[ ds^2 = a^2(\eta) \left[ -\left(1 + 2\phi\right) d\eta^2 + 2\chi_{ij} d\eta dx^i dx^j + (1 - 2R) \delta_{ij} dx^i dx^j \right], \]

where \( a \) is the scale factor and \( \eta \) is the conformal time. We study the cosmological perturbations up to second order, and hence we write

\[ \phi = \phi^{(1)} + \phi^{(2)}, \quad \chi_i = \chi_i^{(2)}, \quad R = R^{(1)} + R^{(2)}, \]

where we have dropped the first-order vector perturbations \( \chi_i^{(1)} \) since they are not generated from inflation in the standard scenarios. We also neglect the tensor perturbations (gravitational waves) for simplicity.

We consider a multi-fluid system composed of photons (\( \gamma \)), electrons (\( e \)) and protons (\( p \)). We assume that the energy–momentum tensor for each fluid component is given by that of a perfect fluid (i.e., we neglect anisotropic stresses):

\[ T^{(I)}_{\mu \nu} = (\rho^{(I)} + p^{(I)}) u^{(I)}_\mu u^{(I)}_\nu + p^{(I)} \delta^{(I)}_{\mu \nu} \quad (I = \gamma, p, e), \]

where \( p_I = w_I \rho_I \) (\( w_\gamma = 1/3 \), \( w_p = 0 \), \( w_e = 0 \)) and \( u^{(I)}_\mu \) is the 4-velocity of the fluid satisfying

\[ g^{\mu \nu} u^{(I)}_\mu u^{(I)}_\nu = -1: \]

\[ u^{(I)}_\mu = \frac{1}{a} \left( 1 - \phi + \frac{3}{2} \phi^2 + \frac{1}{2} v_{(I)j} v_{(I)j} \right), \]

\[ u_{(I)\mu} = a \left( -1 - \phi + \frac{1}{2} \phi^2 - \frac{1}{2} v_{(I)j} v_{(I)j} + \chi_i - 2R v_{(I)i} \right). \]

The energy–momentum tensor of the electromagnetic field is written in terms of the field strength \( F_{\mu \nu} \) as

\[ T^{EM}_{\mu \nu} = F^{\mu \lambda}_{\nu,\lambda} - \frac{1}{4} g^{\mu \nu} F_{\sigma \lambda} F^{\lambda \sigma}. \]

As usual, the field strength is decomposed into the electric and magnetic fields as

\[ E^\mu = F^{\mu \nu} u_{(\gamma)\nu}, \quad B^\mu = \frac{1}{4} \varepsilon^{\mu \nu \lambda} F_{\nu \lambda}, \]

where \( \varepsilon^{\mu \nu \lambda} = \eta^{\mu \nu \lambda \sigma} u_{(\gamma)\sigma} \) with \( \eta_{0123} = 1/\sqrt{-g} \). Here we tacitly adopt the photon frame.
The vorticity, $\omega_i \equiv -\frac{1}{2} \varepsilon^{ijk} u_{(1)j} \nabla_i u_{(1)k}$, is the important quantity in our discussion. The vorticity is given explicitly by \[ \omega_{(1)}(\mathbf{I}) i = -\frac{1}{2} a^2 \varepsilon^{ijk} \partial_j \left[ v_{(1)}(\mathbf{I}) k + \chi_{(1)}^{(2)} k \right] + v_{(1)}^{(1)(1)} v_{(1)}^{(1)(1)} + v_{(1)}^{(1)(1)} v_{(1)}^{(1)(1)} \] where $\varepsilon^{ijk}$ is the three-dimensional flat alternating tensor. Since we are assuming that the first-order vector perturbations vanish, we have $\omega_{(1)}(\mathbf{I}) i = 0$.

During the pre-recombination era photons and charged particles are tightly coupled via Thomson scattering, and charged particles are tightly coupled to each other via Coulomb scattering. The momentum transfer between fluids $\mathbf{I}$ and $\mathbf{J}$ are specified by $\kappa_{IJ}$. The momentum transfer due to Thomson scattering is given by \[ \kappa_{\gamma e} i = -\kappa_{e \gamma} i = -\frac{4}{3} \sigma T n e \rho \gamma \left( u(\gamma) i - u(e) i \right), \] \[ \kappa_{\gamma p} i = -\kappa_{p \gamma} i = -\frac{m_e^2}{m_p^2} \frac{4}{3} \sigma T n p \rho \gamma \left( u(\gamma) i - u(p) i \right), \] where $\sigma_T$, $\rho_\gamma$, $n_e$, $n_p$ and $m_e$, $m_p$ are the Thomson cross section, the energy density of photons, the number density and mass of electrons and protons [11]. Each number density is defined in the rest frame. The difference between frames in the momentum transfer terms appears at third order (in the form of the Lorentz factor) and hence can be neglected. The momentum transfer rate follows from the collision term in the Boltzmann equation. A careful and detailed derivation of equations (14) and (15) (valid at second order) can be found in [14, 21, 22]. The momentum transfer due to Coulomb scattering is written as \[ \kappa_{i e} = -\kappa_{i p} = -e^2 n_p \rho \eta C \left( u(p) i - u(e) i \right), \] where $\eta_C$ is an electric resistivity which comes from Coulomb scattering [14]. To derive the energy conservation law and equations of motion, we compute the divergence of the energy–momentum tensor:

\[ \nabla_i T_{(\mathbf{I})}^{\mu} = -\left[ \rho_i + 3 \mathcal{H} (\rho_i + p_i) \right] + 3 (\rho_i + p_i) \mathcal{H} - (\rho_i + p_i) \partial_i u_{(1)i}, \] \[ \nabla_i T_{(\mathbf{I})}^{\mu} = \left[ (\rho_i + p_i) (v_{(1)i} + \chi_i) \right] + 4 \mathcal{H} (\rho_i + p_i) (v_{(1)i} + \chi_i) + (\rho_i + p_i) \partial_i (\phi - \phi^2) + \partial_i p_i \] \[ - (\phi + 2 \mathcal{H}) \left[ (\rho_i + p_i) (v_{(1)i}) \right] + 4 \mathcal{H} (\rho_i + p_i) v_{(1)i} \] \[ - 3 (\rho_i + p_i) \mathcal{H} v_{(1)i} + (\rho_i + p_i) \partial_i (v_{(1)i} v_{(1)i}), \] where the prime denotes the derivative with respect to $\eta$ and $\mathcal{H} = a'/a$ is the conformal Hubble rate. Note that the energy transfer by Thomson scattering may be ignored\(^4\) [8, 11]. Thus, the equations of motion governing the present 3-fluid system are given by

\[ \nabla_i T_{(\gamma)}^{\mu} = -\kappa_i^{\gamma e} + \kappa_i^{\gamma p}, \] \[ \nabla_i T_{(p)}^{\mu} = en_p E_i + \kappa_i^{\gamma e} + \kappa_i^{p p}, \] \[ \nabla_i T_{(e)}^{\mu} = -en e E_i + \kappa_i^{p p} + \kappa_i^{e e}, \]

\(^4\) More precisely, this approximation is correct up to the first order of cosmological perturbation and we will use only the energy conservation law at the first order to derive the evolution equation for magnetic fields.
where we neglected the Lorentz force from the magnetic field because it will give rise to higher order contributions.

To proceed, it is convenient to define the center-of-mass velocity and the relative velocity as

\[ v(b)i := \frac{v(p)i + \beta v(e)i}{1 + \beta}, \]

\[ \delta v(\gamma J)i := v(J)i - v(\gamma)i, \]  

where \( \beta := m_e/m_p \). Hereafter we will assume charge neutrality: \( n_p = n_e (= n) \) in the rest frame of charged particles. This will be justified because the velocity difference between protons and electrons, \( \delta v(pe)i \), is ignored compared to \( \delta v(\gamma b)i \) in the situation where the Coulomb interaction is very strong.

Now the equation of motion for the photon fluid reads as

\[ \frac{4}{3} \left\{ \rho'_\gamma (v(\gamma)i + \chi_i) + \rho_\gamma (v(\gamma)i + \chi_i)' + 4\mathcal{H}_R (v(\gamma)i + \chi_i) + \frac{1}{4} \delta \rho_\gamma \right\} 
- (\phi + 2\mathcal{R}) \left[ \rho_\gamma v'_i (v(\gamma)i + \chi_i) + 4\mathcal{H}_R v(\gamma)i \right] 
- 5\rho_\gamma \mathcal{R}' v(\gamma)i + \rho_\gamma \partial_i (\phi - \phi^2) + \rho_\gamma \partial_j (v(\gamma)i v'_j) \right\} 
= -\frac{4}{3} a\sigma T n \rho_\gamma \left( 1 - 2\mathcal{R} \right) \left[ (1 + \beta^2) \delta v(\gamma b)i + \frac{1 - \beta^3}{1 + \beta} \delta v(pe)i \right]. \]  

(24)

The equations of motion for the charged particles (20) and (21) are combined to give

\[ m_p (1 + \beta) \left\{ n'(v(b)i + \chi_i) + n(v(b)i + \chi_i)' + 4\mathcal{H}_n (v(b)i + \chi_i) 
- (\phi + 2\mathcal{R}) [n' v'_i (v(b)i + \chi_i) + 4\mathcal{H}_n v(b)i] - 5n \mathcal{R}' v(b)i 
+ n \partial_i (\phi - \phi^2) + \frac{n}{1 + \beta} \partial_j (v(p)i v'_j + \beta v(e)i v'_j) \right\} 
= \frac{4}{3} a\sigma T n \rho_\gamma (1 - 2\mathcal{R}) \left[ (1 + \beta^2) \delta v(\gamma b)i + \frac{1 - \beta^3}{1 + \beta} \delta v(pe)i \right]. \]  

(25)

The equations of motion for the charged particles can be combined in a different way. The manipulation \( m_e n_e \times (20) - m_p n_p \times (21) \) leads to another independent equation:

\[ m_e m_p n \left\{ (n' \delta v(pe)i)' + 4\mathcal{H}_n n \delta v(pe)i - (\phi + 2\mathcal{R}) [(n' \delta v(pe)i)' + 4\mathcal{H}_n \delta v(pe)i] \right. 
- 5n \mathcal{R}' \delta v(pe)i + n \partial_j (v(p)i v'_j + v(e)i v'_j) \right\} 
= e^2 m_p n (1 + \beta) E_i - \frac{4}{3} a\sigma T m_p n^2 \rho_\gamma (1 - 2\mathcal{R}) \left[ (1 - \beta^3) \delta v(\gamma b)i + \frac{1 + \beta^4}{1 + \beta} \delta v(pe)i \right] 
- e^2 m_p n (1 + \beta) \eta \left[ (1 - 2\mathcal{R}) \delta v(pe)i \right]. \]  

(26)

Since the Coulomb interaction is very strong in the regime we consider, we may take the limit \( \delta v(\gamma b)i \gg \delta v(pe)i \rightarrow 0 \). Then equation (26) simply reduces to

\[ E_i = \frac{1 - \beta^3}{1 + \beta} \frac{4\sigma T}{3e} n \rho_\gamma (1 - 2\mathcal{R}) \delta v(\gamma b)i. \]  

(27)
This may be regarded as ‘Ohm’s law’ in some sense. In the standard Ohm’s law, the electric field is proportional to the electric current density $\sim e\delta v_{(pe)i}$. It is recalled that the contribution from the electric current gives us the diffusion term in the evolution equation for the magnetic field and then the source for the magnetic field cannot be induced. However, the electric field is proportional to $\delta v_{(\gamma b)i}$ in the above formula. The current in our ‘Ohm’s law’ is originated from the velocity difference between protons and electrons through the interaction with photons. Indeed, if one takes the same mass limit of $\beta \to 1$ (though it is not realized in the nature), the electric field cannot be generated.

2.2. Magnetic fields

Let us turn to the evolution of the electromagnetic fields. The Bianchi identities, $\nabla_i F_{\mu\nu} = 0$, yield the induction equation

$$ (a^3 B_i')' = -e^{ij} \partial_j \left[ a (1 + \phi) E_k \right] - e^{ij} (a v_j E_k)' . $$

(28)

Using ‘Ohm’s law’ (27), this can be written as

$$ (a^3 B_i')' = \frac{1 - 1}{1 + \beta^3} \frac{4 \sigma_T}{3e} \times e^{jk} a^2 \left[ \partial_j (\rho_\gamma \delta v_{(yb)k}) + \rho_\gamma \partial_j (\phi - 2R) \delta v_{(yb)k} + \frac{1}{a^2} (\rho_\gamma v_j a^2 \delta v_{(yb)k}') \right] . $$

(29)

It is now clear from equation (29) that we need the velocity difference between the photons and the charged particles, $\delta v_{(yb)i}$, to evaluate the generated magnetic field. The velocity difference can be computed as follows. The manipulation $(4 \rho_\gamma / 3)^{-1} \times (24) - [m_p (1 + \beta) n]^{-1} \times (25)$ leads to

$$ \frac{\rho_\gamma'}{\rho_\gamma} (v_{(yb)i} + \chi_i) - \frac{n'}{n} (v_{(yb)i} + \chi_i) + (\delta v_{(yb)i})' + 4 \gamma \delta v_{(yb)i} $$

$$ - (\phi + 2R) \left[ \frac{\rho_\gamma'}{\rho_\gamma} \delta v_{(yb)i} - \frac{n'}{n} v_{(yb)i} + (\delta v_{(yb)i})' + 4 \gamma \delta v_{(yb)i} \right] $$

$$ - 5R' \delta v_{(yb)i} + \frac{1}{4} \partial_j \left[ \rho_\gamma v_j v_{(yb)i} - \partial_j (v_{(yb)i} v_{(yb)i}') \right] $$

$$ = -\alpha (1 - 2R) \delta v_{(yb)i} , $$

(30)

where $\alpha$ is defined as

$$ \alpha := \frac{1 + \beta^2}{1 + \beta} \left[ 1 + \frac{4 \sigma_T \rho_\gamma}{3 m_p} \right] \left[ 4 \beta (1 + \beta^2) (1 + R) \frac{1}{\tau_T} \right] $$

(31)

with

$$ R := \frac{3 m_p (1 + \beta) n}{4 \rho_\gamma} $$

(32)

and

$$ \tau_T := \frac{m_e}{4 \sigma_T \rho_\gamma} . $$

(33)

In deriving the above equation we again used $\delta v_{(pe)i} \ll \delta v_{(yb)i}$. Thus, our remaining task is to solve equation (30) for $\delta v_{(yb)i}$. 
3. Tight coupling approximation

We are to solve equation (30) using the tight coupling approximation (TCA) [16]. In this approximation the timescale of Thomson scattering ($\tau_T = m_e/a \sigma_T \rho_\gamma$) is assumed to be much smaller than the wavelengths of the perturbations ($k^{-1}$). Thus, the small expansion parameter of the TCA is $k \tau_T$, which is dimensionless. During the pre-recombination era, photons, protons and electrons are strongly coupled via Thomson scattering, and hence the TCA will be a good approximation.

At zeroth order in the TCA, all fluid components have the same velocity $v_i$ and the density fluctuations are adiabatic. Following [14], we define the deviation from the adiabatic distribution for baryons by

$$n_b = \bar{n}_b (1 + \Delta_b) .$$

Then, we expand various quantities such as $\Delta_b$ and $v_i$ in terms of the tight coupling parameter $k \tau_T$:

$$\Delta_b = \Delta_b^{(I)} + \Delta_b^{(II)} + \cdots ,$$

$$v_{(\gamma)i} = v_i ,$$

$$v_{(b)i} = v_i + v_{(I)(b)i} + v_{(II)(b)i} + \cdots ,$$

$$\delta v_{(\gamma b)i} = \delta v_{(I)(\gamma b)i} + \delta v_{(II)(\gamma b)i} + \cdots ,$$

where $v_i$ is the common velocity of photons and baryons in the tight coupling limit. Our notation is that Roman and Arabic numerals stand for the order of TCA and that in cosmological perturbation theory, respectively. Here, we adopt the photon frame, so that $\Delta_\gamma^{(I)} = \Delta_\gamma^{(II)} = 0$. In other words, the quantities associated with photons give the ‘background’ in the TCA. Note that we consider cosmological perturbation theory and the TCA simultaneously. The following analysis includes cosmological perturbations up to second-order and the tight coupling expansion up to TCA(II), where TCA($n$) denotes the tight coupling approximation at $n$th order. The notation $X^{(n,m)}$ indicates that $X$ is an $m$th-order quantity in cosmological perturbation theory at TCA($n$).

At each order in the TCA ($n = I, II$), equation (29) reduces to

$$\left[ (a^3 B')^y \right]^{(n)} = -\frac{1 - \beta^3 4 \sigma_T}{1 + \beta} a^2 \bar{\rho}_\gamma^{(0)} (S^y_B)^{(n)} ,$$

where

$$(S^y_B)^{(n)} = e^{ijk} \left[ \partial_j \delta v_{(\gamma b)k}^{(n,2)} + \frac{1}{\bar{\rho}_\gamma^{(0)}} \partial_j (\delta \bar{\rho}_\gamma^{(1)} \delta v_{(\gamma b)k}^{(n,1)}) + \partial_j (\phi^{(1)} - 2 R^{(1)}) \delta v_{(\gamma b)k}^{(n,1)} + \frac{1}{a^2 \bar{\rho}_\gamma^{(0)}} (a^2 \bar{\rho}_\gamma^{(0)} v_j^{(1)\gamma} \delta v_{(\gamma b)k}^{(n,1)\gamma})' \right] .$$

We shall now evaluate the source term $(S^y_B)^{(n)}$.

3.1. TCA(0)

3.1.1. Energy conservation. At (0, 0) order, equation (17) reads

$$\left( \bar{\rho}_\gamma^{(0)} \right)' + 4 \gamma \bar{\rho}_\gamma^{(0)} = 0 , \quad \left( \bar{\rho}_\gamma^{(0)} \right)' + 3 \gamma \bar{n}^{(0)} = 0 .$$

At the next order in cosmological perturbation theory, i.e., at (0, 1) order, we similarly have
\[- (\delta \bar{\rho}(1)^{\gamma})' - 4\mathcal{H}(\delta \bar{\rho}(1)^{\gamma} + 4\bar{\rho}^{(0)}_\gamma)(\mathcal{R}(1)^{\gamma})' - \frac{4}{3}\bar{\rho}^{(0)}_\gamma \partial_i v^{(1)} = 0, \tag{42}\]
\[- (\delta \bar{n}(1)^{\gamma})' - 3\mathcal{H}(\delta \bar{n}(1)^{\gamma} + 3\bar{n}^{(0)}_\gamma)(\mathcal{R}(1)^{\gamma})' - \bar{n}^{(0)}_\gamma \partial_i v^{(1)} = 0. \tag{43}\]

These equations can be put into
\[
\left(\frac{\delta \bar{\rho}(1)^{\gamma}}{\bar{\rho}^{(0)}_\gamma}\right)' = 4(\mathcal{R}(1)^{\gamma})' - \frac{4}{3}\partial_i v^{(1)}, \quad \left(\frac{\delta \bar{n}(1)^{\gamma}}{\bar{n}^{(0)}_\gamma}\right)' = 3(\mathcal{R}(1)^{\gamma})' - \partial_i v^{(1)}, \tag{44}\]

implying that
\[
\left(\frac{\delta \bar{\rho}(1)^{\gamma}}{\bar{\rho}^{(0)}_\gamma}\right)' = 4\left(\frac{\delta \bar{n}(1)^{\gamma}}{\bar{n}^{(0)}_\gamma}\right)'. \tag{45}\]

### 3.1.2. Vorticity.

We show that the vorticity vanishes at TCA(0). Using equation (41), the momentum conservations for photons and baryons at (0, 1) order are
\[
\left(v^{(1)}_i\right)' + \frac{1}{4} \frac{\partial_i \delta \bar{\rho}(1)}{\bar{\rho}^{(0)}_\gamma} + \partial_i \phi^{(1)} = 0, \quad \left(v^{(1)}_i\right)' + \mathcal{H}v^{(1)}_i + \partial_i \phi^{(1)} = 0. \tag{46}\]

We eliminate \(v^{(1)}_i\) from the above equations and obtain the relation
\[
\mathcal{H}v^{(1)}_i = \frac{1}{4} \frac{\partial_i \delta \bar{\rho}(1)}{\bar{\rho}^{(0)}_\gamma}. \tag{47}\]

At (0, 2) order, we eliminate similarly \(v^{(2)}_i + \chi^{(2)}_i\). The momentum conservation gives
\[
\left(v^{(2)}_i + \chi^{(2)}_i\right) - (\phi^{(1)} + 2\mathcal{R}(1))v^{(1)}_i - \frac{1}{47} \left(-\frac{\delta \bar{\rho}(1)}{\bar{\rho}^{(0)}_\gamma} \delta \bar{\rho}^{(1)} + \frac{\partial_i \delta \bar{\rho}(2)}{\bar{\rho}^{(0)}_\gamma}\right)
+ \frac{1}{47\mathcal{H}^2} \left(-\left(\mathcal{R}(1)\right)' + \frac{1}{3} \partial_i v^{(1)}\right)\frac{\partial_i \delta \bar{\rho}(1)}{\bar{\rho}^{(0)}_\gamma} = 0. \tag{48}\]

Taking the curl of the above equation and using equation (47), we can show that \(\omega^{(2)} = 0\). It indicates that the vorticity is always zero at TCA(0).

### 3.2. TCA(1)

#### 3.2.1. Energy conservation.

To compute \(\delta v^{(I,2)}_{(y)\beta}\), we evaluate \(\Delta^{(I,1)}_b\) using the energy conservation. At \((I, 1)\) order, equation (17) reduces to
\[
-(\bar{n}^{(0)}_\gamma)\Delta^{(I,1)}_b' - 3\mathcal{H}\bar{n}^{(0)}_\gamma\Delta^{(I,1)}_b - \bar{n}^{(0)}_\gamma \partial_i v^{(I,1)}_{(y)\beta} = 0, \tag{49}\]

and hence
\[
\left(\Delta^{(I,1)}_b\right)' + \partial_i v^{(I,1)}_{(y)\beta} = 0, \tag{50}\]

which is integrated to give
\[
\Delta^{(I,1)}_b = \int_\eta^\infty d\eta \partial_i v^{(I,1)}_{(y)\beta}. \tag{51}\]
3.2.2. Vorticity evolution equation. To derive the vorticity evolution equation, we take the curl of the total momentum conservation. The total momentum conservation is

\[
\left( \frac{4}{3} \rho \gamma v_{(\gamma) i} + \rho_b v_{(b) i} + \rho_T \chi_i \right) + 4 \mathcal{H} \left( \frac{4}{3} \rho \gamma v_{(\gamma) i} + \rho_b v_{(b) i} \right)
\]

\[
+ 4 \mathcal{H} \rho_T \chi_i - 5 \mathcal{R} \left[ \left( \frac{4}{3} \rho \gamma v_{(\gamma) i} + \rho_b v_{(b) i} \right) + \frac{1}{3} \partial_i \rho_T \right]
\]

\[- (\phi + 2 \mathcal{R}) \left[ \left( \frac{4}{3} \rho \gamma v_{(\gamma) i} + \rho_b v_{(b) i} \right) + 4 \mathcal{H} \left( \frac{4}{3} \rho \gamma v_{(\gamma) i} + \rho_b v_{(b) i} \right) \right]
\]

\[+ \rho_T \partial_i (\phi - \phi^2) + \sum_I \rho_I (1 + w_I) \partial_j (v_{(I)i} v_{(I)j}) = 0,
\]

(52)

where \( \rho_b = m_p (1 + \beta)n \). Note that the scattering terms are cancelled out. At TCA(I), this equation is simplified to

\[
[\rho_T (v_i + \chi_i)] + 4 \mathcal{H} \rho_T (v_i + \chi_i) + \rho_T \partial_i (\phi - \phi^2) + \frac{1}{3} \partial_i \rho_T
\]

\[- (\phi + 2 \mathcal{R}) \left[ \left( \rho_T v_i \right) + 4 \mathcal{H} \rho_T v_i \right] - 5 \mathcal{R} \mathcal{R}' v_i + \rho_T \partial_j (v_i v_j) = 0,
\]

(53)

where \( \rho_T \) is defined by

\[
\rho_T := \frac{4}{3} \rho_T + \rho_b = \frac{4}{3} \rho_T (1 + R).
\]

(54)

At (0, 1) order, equation (30) reads

\[
\left( \frac{v^{(1)}_i}{\rho^{(0)}_T} \right)' + \frac{1}{\rho^{(0)}_T} \left[ \phi^{(0)}_T \right]' v^{(1)}_i + \mathcal{H} v^{(1)}_i + \frac{1}{3} \partial_i \rho^{(1)}_T + \partial_i \phi^{(1)} = 0,
\]

(55)

or, equivalently,

\[
\left( \frac{v^{(1)}_i}{\rho^{(0)}_T} \right)' + \mathcal{H} \frac{\mathcal{R}^{(0)}}{1 + \mathcal{R}^{(0)}} v^{(1)}_i = - \frac{1}{4(1 + \mathcal{R}^{(0)})} \frac{\partial_i \rho^{(1)}_T}{\rho^{(0)}_T} - \partial_i \phi^{(1)}.
\]

(56)

Taking the curl of equation (53), we arrive at the vorticity conservation equation (for the photon fluid):

\[
(2 \alpha^2 \rho_T^{(0)} \omega^{(2)}_i)' + 8 \mathcal{A}^2 \mathcal{H} \rho_T^{(0)} \omega^{(2)} = 0,
\]

(57)

where we used equation (56). It is important to note here that there is no source for the vorticity at TCA(I). Therefore, we may assume that \( \omega^{(2)}_i = 0 \) at TCA(I).

3.2.3. Derivation of \( \delta v^{(1)}_{(\gamma b) i} \) and \( \delta v^{(2)}_{(\gamma b) i} \). At (I, 1) order, equation (30) reads

\[
\left[ \frac{\rho^{(0)}_T}{\rho^{(0)}_T} - \frac{\mathcal{R}^{(0)}}{\mathcal{R}^{(0)}} \right] v^{(1)}_i + 1 \frac{\partial_i \rho^{(1)}_T}{\rho^{(0)}_T} = - \frac{1}{\alpha^{(0)}} \frac{\mathcal{H}}{4} \delta v^{(1)}_{(\gamma b) i},
\]

(58)

and so we have

\[
\delta v^{(1)}_{(\gamma b) i} = \frac{1}{\alpha^{(0)}} \left[ \mathcal{H} v^{(1)}_i - \frac{1}{4} \frac{\partial_i \rho^{(1)}_T}{\rho^{(0)}_T} \right],
\]

(59)

where

\[
\alpha^{(0)} = \frac{(1 + \beta^2)(1 + \mathcal{R}^{(0)}) 4 \mathcal{A} \mathcal{H} \rho_T^{(0)}}{3 m_p}.
\]

(60)
At the next order in cosmological perturbation theory, i.e., at \((I, 2)\) order, we have

\[
\left[ \frac{\delta \rho^{(1)}_\gamma}{\bar{\rho}^{(0)}_\gamma} \right] = - \left( \frac{\rho^{(0)}_\gamma}{\bar{\rho}^{(0)}_\gamma} \right)' \frac{\delta \bar{n}^{(1)}_\gamma}{\bar{n}^{(0)}_\gamma} - \left( \frac{\delta \bar{n}^{(1)}_\gamma}{\bar{n}^{(0)}_\gamma} \right)' \bar{\rho}^{(0)}_\gamma
\]

\[
+ \left( \frac{\rho^{(0)}_\gamma}{\bar{\rho}^{(0)}_\gamma} \right)' \left[ \left( \frac{\delta \rho^{(1)}_\gamma}{\bar{\rho}^{(0)}_\gamma} \right)' \frac{\delta \bar{n}^{(1)}_\gamma}{\bar{n}^{(0)}_\gamma} \right] \left( \frac{\delta \rho^{(0)}_\gamma}{\bar{\rho}^{(0)}_\gamma} \right)' \left( \frac{\delta \bar{n}^{(1)}_\gamma}{\bar{n}^{(0)}_\gamma} \right)' \bar{\rho}^{(0)}_\gamma
\]

\[
\left( \frac{\delta \rho^{(1)}_\gamma}{\bar{\rho}^{(0)}_\gamma} \right)' \left( \frac{\delta \bar{n}^{(1)}_\gamma}{\bar{n}^{(0)}_\gamma} \right)' \bar{\rho}^{(0)}_\gamma
\]

\[
\left( \frac{\delta \rho^{(0)}_\gamma}{\bar{\rho}^{(0)}_\gamma} \right)' \left( \frac{\delta \bar{n}^{(1)}_\gamma}{\bar{n}^{(0)}_\gamma} \right)' \bar{\rho}^{(0)}_\gamma
\]

\[
\left( \frac{\delta \rho^{(0)}_\gamma}{\bar{\rho}^{(0)}_\gamma} \right)' \left( \frac{\delta \bar{n}^{(1)}_\gamma}{\bar{n}^{(0)}_\gamma} \right)' \bar{\rho}^{(0)}_\gamma.
\]

where

\[
\delta v^{(I, 2)}(\gamma b) = \frac{1}{\bar{\rho}^{(0)}_\gamma} \rho^{(0)}_\gamma \alpha^{(0)} \left[ \delta \rho^{(1)}_\gamma + \frac{3}{4} (m_\gamma + m_\alpha) \delta \bar{n}^{(1)}_\gamma \right] = \frac{4 + 3 \bar{R}^{(0)}_\gamma \rho^{(0)}_\gamma \delta \bar{n}^{(1)}_\gamma}{4(1 + \bar{R}^{(0)}_\gamma)} \alpha^{(0)} \frac{\delta \rho^{(1)}_\gamma}{\bar{\rho}^{(0)}_\gamma}.
\]

This can be solved for \(\delta v^{(I, 2)}(\gamma b)\) to give

\[
\delta v^{(I, 2)}(\gamma b) = \frac{1}{\alpha^{(0)}} \left[ \mathcal{H} \left( v^{(2)} + \chi^{(2)}_i - \frac{\bar{\rho}^{(0)}_\gamma}{\bar{\rho}^{(0)}_\gamma} \right) \left( \frac{\delta \rho^{(1)}_\gamma}{\bar{\rho}^{(0)}_\gamma} \right)' \frac{\delta \bar{n}^{(1)}_\gamma}{\bar{n}^{(0)}_\gamma} \right]
\]

\[
+ \mathcal{H} \delta v^{(I, 1)}_\gamma - \frac{1}{\alpha^{(0)}} \left[ \frac{\partial \delta v^{(1)}_\gamma}{\partial \gamma} \right] \left( \frac{\delta \rho^{(1)}_\gamma}{\bar{\rho}^{(0)}_\gamma} \right)' \frac{\delta \bar{n}^{(1)}_\gamma}{\bar{n}^{(0)}_\gamma} \left( \frac{\delta \rho^{(0)}_\gamma}{\bar{\rho}^{(0)}_\gamma} \right)' \frac{\delta \bar{n}^{(1)}_\gamma}{\bar{n}^{(0)}_\gamma} \left( \frac{\delta \rho^{(0)}_\gamma}{\bar{\rho}^{(0)}_\gamma} \right)'
\]

\[
\left( \frac{\delta \rho^{(0)}_\gamma}{\bar{\rho}^{(0)}_\gamma} \right)' \left( \frac{\delta \bar{n}^{(1)}_\gamma}{\bar{n}^{(0)}_\gamma} \right)' \bar{\rho}^{(0)}_\gamma.
\]

3.3. TCA(I)

3.3.1. Derivation of \(\delta v^{(I, 1)}_\gamma\) and \(\delta v^{(I, 2)}_\gamma\). Equation (30) at order \((I, 1)\) and \((I, 2)\) allows us to obtain the expression for \(\delta v^{(I, 1)}_\gamma\) and \(\delta v^{(I, 2)}_\gamma\), respectively. At first order in cosmological perturbation theory, we have

\[
\delta v^{(I, 1)}_\gamma = - \frac{1}{\alpha^{(0)}} \left[ \left( \frac{\delta \rho^{(1)}_\gamma}{\bar{\rho}^{(0)}_\gamma} \right)' \frac{\delta \bar{n}^{(1)}_\gamma}{\bar{n}^{(0)}_\gamma} + 4 \mathcal{H} \delta v^{(I, 1)}_\gamma = - \bar{\alpha}^{(0)} \delta v^{(I, 1)}_\gamma,
\]

yielding

\[
\delta v^{(I, 1)}_\gamma = - \frac{1}{\bar{\rho}^{(0)}_\gamma} \left( \delta v^{(I, 1)}_\gamma \right)' + \mathcal{H} \delta v^{(I, 1)}_\gamma.
\]

At second order in cosmological perturbation theory, we get

\[
\left( \delta v^{(I, 2)}_\gamma \right)' + \mathcal{H} \delta v^{(I, 2)}_\gamma - \left( \frac{\delta v^{(I, 1)}_\gamma}{\bar{\rho}^{(0)}_\gamma} \right)' \left( \delta v^{(I, 1)}_\gamma \right)' - 2 (\mathcal{H} \delta v^{(I, 1)}_\gamma) - 2 (\mathcal{H} \delta v^{(I, 1)}_\gamma)
\]

\[
+ \left( \delta v^{(I, 1)}_\gamma \right)' \left( \delta v^{(I, 1)}_\gamma \right)' + \left( \delta v^{(I, 1)}_\gamma \right)' \left( \delta v^{(I, 1)}_\gamma \right)' \bar{\rho}^{(0)}_\gamma
\]

\[
\left( \delta v^{(I, 1)}_\gamma \right)' \left( \delta v^{(I, 1)}_\gamma \right)' \bar{\rho}^{(0)}_\gamma.
\]

From this we obtain

\[
\delta v^{(I, 2)}_\gamma = - \frac{1}{\alpha^{(0)}} \left[ \left( \delta v^{(I, 2)}_\gamma \right)' + \mathcal{H} \delta v^{(I, 2)}_\gamma \right] + \bar{\alpha}^{(1)} \left( \delta v^{(I, 1)}_\gamma \right)' + \mathcal{H} \delta v^{(I, 1)}_\gamma - \frac{\alpha^{(1)} \delta v^{(I, 1)}_\gamma}{\alpha^{(0)}} \delta v^{(I, 1)}_\gamma
\]

\[
+ \frac{1}{\alpha^{(0)}} \left[ \left( \delta v^{(I, 1)}_\gamma \right)' + \mathcal{H} \delta v^{(I, 1)}_\gamma \right] \left( \delta v^{(I, 1)}_\gamma \right)' + \mathcal{H} \delta v^{(I, 1)}_\gamma
\]

\[
+ 2 (\mathcal{H} \delta v^{(I, 1)}_\gamma) \delta v^{(I, 1)}_\gamma - \frac{\alpha^{(1)} \delta v^{(I, 1)}_\gamma}{\alpha^{(0)}} \delta v^{(I, 1)}_\gamma + \frac{\alpha^{(1)} \delta v^{(I, 1)}_\gamma}{\alpha^{(0)}} \delta v^{(I, 1)}_\gamma
\]

\[
\left( \delta v^{(I, 1)}_\gamma \right)' \left( \delta v^{(I, 1)}_\gamma \right)' \bar{\rho}^{(0)}_\gamma.
\]

where we used equation (65) and note that

\[
\frac{\alpha^{(1)} \delta v^{(I, 1)}_\gamma}{\alpha^{(0)}} = \frac{\tilde{R}^{(0)}_\gamma}{1 + \tilde{R}^{(0)}_\gamma} \delta v^{(I, 1)}_\gamma = \frac{\tilde{R}^{(0)}_\gamma}{1 + \tilde{R}^{(0)}_\gamma} \int d\eta \frac{\partial \delta v^{(I, 1)}_\gamma}{\partial \gamma}.
\]
3.3.2. Vorticity evolution equation. In order to derive the vorticity evolution equation at TCA(II), we need to consider equation (52) at TCA(I). At \((I, 1)\) order, equation (52) reads

\[
\left( v_i^{(I)} \right)' = -\frac{\gamma \dot{R}^{(0)}}{1 + R^{(0)}} v_i^{(1)} - \frac{1}{4(1 + R^{(0)})} \frac{\partial_j \phi^{(I)}}{\rho^{(0)}} - \partial_j \phi^{(I)} + \frac{\gamma \dot{R}^{(0)}}{1 + R^{(0)}} \left[ \delta v_{(i,1)}^{(I)} \right]' + \gamma \delta v_{(i,1)}^{(I)}[
\]

(69)

where we used equations (41) and (54). We take the curl of equation (52) at \((I, 2)\) order, so that we obtain

\[
(\alpha^2 \omega^{(2i)})' = \frac{2\gamma \dot{R}^{(0)}}{1 + R^{(0)}} \omega^{(2i)} = \frac{1}{2(1 + R^{(0)})} \epsilon^{ijk} \partial_j \alpha^{(I,1)} \delta v_{(y,bk)}^{(I,1)}
\]

(70)

where we used equation (69) and

\[
\epsilon^{ijk} \partial_j \delta v_{(y,bk)}^{(I,2)} = -\frac{2\alpha^2 \gamma}{a^{(0)}} \omega^{(2i)} + 2\epsilon^{ijk} \partial_j R^{(1)} \delta v_{(y,bk)}^{(I,1)} - \epsilon^{ijk} \partial_j v^{(I)}_{(1)} \left[ \delta v_{(y,bk)}^{(I,1)} \right]' + \gamma \delta v_{(y,bk)}^{(I,1)}
\]

(71)

Since the right-hand side of equation (70) contains the source term for the vorticity at TCA(II), the vorticity can be generated at this order.

3.4. Generation of magnetic fields

To evaluate the magnetic fields we substitute \(\delta v_{(y,bk)}^{(1,m)}\) (i.e., equations (59), (63), (65) and (67)) into the source term for magnetic fields (i.e., equation (40)). It is easy to see that the source term at TCA(I) is given by

\[
\left( S_b^{(I)} \right)' = -\frac{2\alpha^2 \gamma}{a^{(0)}} \omega^{(2i)}
\]

(72)

where we used equations (56) and (71). This turns out to be proportional to the vorticity of the photon fluid. Indeed, we find

\[
[\left( a^3 B^i \right)']^{(I)} = 2 \frac{1 - \beta^3}{1 + \beta} \frac{4\sigma}{3e} a^2 \rho_{(0)}^{(0)} \frac{\gamma \dot{R}^{(0)}}{a^{(0)}} \omega^{(2i)}
\]

(73)

If one assumes a vanishing initial vorticity (see the argument around equation (57)), magnetic fields cannot be produced at TCA(I).

The source term which we consider up to TCA(II) is expressed as

\[
\left( S_b^{(I)} \right)' = \left( S_b^{(I)} \right)'^{(I)} + \left( S_b^{(I)} \right)'^{(II)} = -\frac{2\alpha^2 \gamma}{a^{(0)}} \omega^{(2i)} - \epsilon^{ijk} \partial_j \alpha^{(I,1)} \delta v_{(y,bk)}^{(I,1)},
\]

(74)

where \(\alpha^{(0)}, \alpha^{(I,1)}\) and \(\delta v_{(y,bk)}^{(I,1)}\) are given by equations (60), (68) and (59), respectively. Note in passing that \(\delta v_{(y,bk)}^{(I,1)}'\) is computed as

\[
\left( \delta v_{(y,bk)}^{(I,1)} \right)' = \frac{\gamma \dot{R}^{(0)}}{1 + R^{(0)}} \left( \delta v_{(y,bk)}^{(I,1)} \right)' + \frac{1}{a^{(0)}} \left( \left[ \left( \delta v_{(y,bk)}^{(I)} \right)' - \frac{1}{4} \partial_j \left( \delta \phi_{(y,bk)}^{(I)} \right)' \right] \right).
\]

(75)

Hence, we get

\[
(\alpha^3 B^i)' = \frac{1 - \beta^3}{1 + \beta} \frac{4\sigma}{3e} a^2 \rho_{(0)}^{(0)} \left[ \frac{2\alpha^2 \gamma}{a^{(0)}} \omega^{(2i)} + \epsilon^{ijk} \frac{\dot{R}^{(0)}}{1 + R^{(0)}} \partial_j \Delta_{(y,bk)}^{(I,1)} \delta v_{(y,bk)}^{(I,1)} \right].
\]

(76)

where we used equation (68). Intrinsically second-order perturbations appear only as \(\omega^{(2i)}\) in the source term, which is governed by equation (70). We can check that equation (76) is the same as the result obtained in [11]. Note that the vorticity is the general relativistic effect because it vanishes in the limit of \(\gamma \rightarrow 0\). Taking the Newton limit \((\gamma \rightarrow 0)\), only the last
term in the right-hand side of equation (76) remains. At first glance, this result is not the same as one obtained in [14] where the tight coupling approximation was employed in Newtonian theory. This is not surprising because photon’s rest frame is not used as the background of the tight coupling approximation in [14]. Performing an appropriate coordinate transformation, therefore, we can show that our result agrees exactly with [14].

Now we are ready to give an estimate of the magnetic field generated from second-order cosmological perturbations at the recombination epoch. For clarity and simplicity, we focus on the magnetic fields on the horizon scales ($k \sim \mathcal{H}$). We find $R \sim \delta$ by using the first-order Einstein equations and $v \sim (\mathcal{H}/k) \delta \sim \delta$ by using equation (44) on the horizon scales, where $\delta \equiv \delta \tilde{\rho}_\gamma^{(1)}/\tilde{\rho}_\gamma^{(0)}$. Finally, the magnetic field on the horizon scales is estimated to be

$$B \sim \sqrt{B^i B_i} \sim \frac{a^2 m_p^2 k^2}{\sigma T} \left( \frac{\tilde{\rho}_\gamma^{(0)}}{a^4} \right) \delta^2 \sim 10^{-29} \text{ G},$$

where we used $a \sim 10^{-3}$, $k \sim (100 \text{ Mpc})^{-1} \sim 0.64 \times 10^{-40} \text{ GeV}$, $e \sim 0.3$, $m_p \sim 0.94 \text{ GeV}$, $\sigma T \sim 1.7 \times 10^{-4} (\text{ GeV})^{-2}$ and $\tilde{\rho}_\gamma^{(0)} a^4 \approx \rho_{\gamma 0} \sim 2.1 \times 10^{-51} (\text{ GeV})^4$. This result is consistent with the result in [9, 11, 13]. According to [2], this will be amplified enough to explain the present observed magnetic fields.

4. Summary

In this paper, we have derived an analytic formula for the magnetic fields generated from second-order cosmological perturbations in the pre-recombination era. Since first-order vector perturbations are not generated from inflation in the standard scenarios, we must go beyond the linear analysis to generate magnetic fields. Photons and charged particles are strongly coupled via Thomson scattering within the cosmic plasma and hence the system behaves almost as a single fluid. In this single-fluid description magnetic fields are never generated and therefore the tiny deviation from the single-fluid description is crucial here. Using the tight coupling approximation (TCA) to treat the small difference between photons and charged particles, we have seen how magnetic fields are generated from cosmic inhomogeneities. It was found that magnetic fields are not generated at first order in the TCA. Therefore, we conclude that magnetogenesis requires both the second-order cosmological perturbations and the second-order TCA. The resultant magnetic fields are expressed in terms of the vorticity and the product of the first-order perturbations. The latter can be computed by solving the linear Einstein equations, while the former is governed by the vorticity evolution equation, with the source term given by the product of the first-order terms. Finally, we gave an order of magnitude estimate for the magnetic fields generated on the horizon scales around the recombination epoch. The result was $B \sim 10^{-29} \text{ G}$. This magnetic field will be enhanced by the dynamo mechanism during and after galaxy formation to explain the present order of the magnitude of the observed magnetic fields [2]. Although our rough estimate suggests that the current generation mechanism can work even on smaller scales, say Mpc, more careful investigation is needed to make clear whether it indeed works in a wide range of spatial scales.

This work is the general relativistic version of [14], including the effects of the cosmic expansion and metric perturbations. The qualitative conclusion derived in this paper confirms the basic results obtained from the fully nonlinear, covariant analysis of [11]. However, our formulation here is based on cosmological perturbation theory, which will be more useful for actual calculations, e.g., of the spectrum of the magnetic fields.

We have not included the effect of anisotropic stresses of photon fluids and the recombination process, though they will be equally important for magnetogenesis on small
scales [12, 13, 15]. Taking into account these effects and computing the power spectrum of the generated magnetic fields require detailed numerical calculations, which are left for forthcoming publications.

Appendix. Consistency with [11]

We show that our result can be identified to that obtained by using the covariant approach [11]. The final result in [11] is

$$
\dot{\mathcal{B}} = -\frac{2}{3} \frac{m_p}{e} \frac{R}{4(1 + R)^2} \frac{1 - \beta^3}{1 + \beta^2} e^{\nu b c \Delta_{(1)}} D_b \rho_{\nu} D_c \rho_{\nu} \rho_{\nu} - \frac{m_p}{e} \frac{R}{2(1 + R)} \frac{1 - \beta^3}{1 + \beta^2} \rho_{\nu} \rho_{\nu} \rho_{\nu} \varepsilon_{\mu \nu \rho \sigma} D^{(1)}(\Delta_{(1)}) D_{\mu} \rho_{\nu} D_{\rho} \rho_{\sigma} \rho_{\sigma} \rho_{\sigma}.
\tag{A.1}
$$

Here $\Delta_{(1)}$ is baryon’s density fluctuation at TCA(I), $\theta \equiv \nabla au^a$ is the volume expansion rate, $\sigma_{ab} \equiv h_{ab} \nabla_a u^a$ is the shear, $\dot{A}_a \equiv h_a^b u^c \nabla_b A_{(1)}$, $f \equiv u^a \nabla_a f$, and $D_a \equiv h_a^b \nabla_b$ for a scalar function.

Equation (A.1) is the nonlinear result. For purpose of comparison we expand equation (A.1) in terms of cosmological perturbations up to second order. We use the perturbed metric (1), and photon’s 4-velocity is defined by equations (4) and (5). Using our notation, the $i$th component of equation (A.1) is

$$
\dot{B}_{(2)i} + \frac{2}{3} \theta^{(0)} B_{(2)i} = -\frac{m_p}{e} \frac{R^{(0)}}{4(1 + R^{(0)})^2} \frac{1 - \beta^3}{1 + \beta^2} e^{\mu \nu \sigma} D_{\mu} \Delta_{(1)}^{(i)} \frac{D_{\nu} \rho_{\nu}^{(1)}}{\rho_{\nu}^{(0)}} - \frac{m_p}{e} \frac{R^{(0)}}{2(1 + R^{(0)})} \frac{1 - \beta^3}{1 + \beta^2} \dot{\rho}_{\nu}^{(0)} \rho_{\nu}^{(0)} \varepsilon_{\mu \nu \rho \sigma} \omega^{(2)i}.
\tag{A.5}
$$

We neglect the shear which is higher order in cosmological perturbations. First, we calculate the left-hand side. Using equation (A.2) and $\theta^{(0)} = 3 \mathcal{H}/a$, we find

$$
\dot{B}^{(2)i} + \frac{2}{3} \theta^{(0)} B^{(2)i} = h^i_{\mu} u^\nu_{(j)} \nabla_{(j)} B^{(2)i} + 2 \frac{\mathcal{H}}{a} B^{(2)i} = u^\nu_{(j)} \nabla_{(j)} B^{(2)i} + 2 \frac{\mathcal{H}}{a} B^{(2)i}.
\tag{A.5}
$$
Second, we calculate the second term in the right-hand side. Using equations (41) and (A.2), we obtain

\[
\frac{m_p}{e} \left[ \frac{\bar{R}(0)}{2(1 + \bar{R}(0))} \right] \left( 1 - \beta^3 \frac{\rho_y^{(0)}}{\bar{R}^{(0)}} \right) \left( 1 - \beta^3 \frac{\bar{R}^{(0)}}{2(1 + \bar{R}(0))} \right) \omega^{(2)i} = \frac{m_p}{e} \left[ \frac{\bar{R}^{(0)}}{2(1 + \bar{R}(0))} \right] \left( 1 - \beta^3 \frac{\rho_y^{(0)}}{\bar{R}^{(0)}} \right) \left( 1 - \beta^3 \frac{\bar{R}^{(0)}}{2(1 + \bar{R}(0))} \right) \omega^{(2)i} = - \frac{m_p}{e} \left[ \frac{\bar{R}^{(0)}}{2(1 + \bar{R}(0))} \right] \left( 1 - \beta^3 \frac{\rho_y^{(0)}}{\bar{R}^{(0)}} \right) 2\mathcal{H} \omega^{(2)i}. \quad (A.7)
\]

Third, we calculate the first term in the right-hand side. Using equation (A.4) we get

\[
\frac{m_p}{e} \left[ \frac{\bar{R}(0)}{4(1 + \bar{R}(0))^2} \right] \left( 1 - \beta^3 \frac{\rho_y^{(0)}}{\bar{R}^{(0)}} \right) \epsilon^{ijk} \delta_v \Delta_b^{(t,1)} \left( \bar{v}^{(1)} \right) = - \frac{m_p}{e} \left[ \frac{\bar{R}^{(0)}}{4(1 + \bar{R}(0))^2} \right] \left( 1 - \beta^3 \frac{\rho_y^{(0)}}{\bar{R}^{(0)}} \right) \epsilon^{ijk} \delta_v \Delta_b^{(t,1)} \left( \bar{v}^{(1)} \right). \quad (A.8)
\]

Finally, we substitute equations (A.6)–(A.8) to equation (A.5), and then we get

\[
(a^3 B^{(2)i})' = \frac{m_p}{e} \left[ \frac{\bar{R}(0)}{4(1 + \bar{R}(0))^2} \right] \left( 1 - \beta^3 \frac{\rho_y^{(0)}}{\bar{R}^{(0)}} \right) \epsilon^{ijk} \delta_v \Delta_b^{(t,1)} \left( \bar{v}^{(1)} \right) + \frac{m_p}{e} \left[ \frac{\bar{R}^{(0)}}{4(1 + \bar{R}(0))^2} \right] \left( 1 - \beta^3 \frac{\rho_y^{(0)}}{\bar{R}^{(0)}} \right) 2a^4 \mathcal{H} \omega^{(2)i}. \quad (A.9)
\]

Using equation (60), equation (A.9) can be recast in

\[
(a^3 B^{(2)i})' = \frac{1 - \beta^3}{1 + \beta^3} \frac{4\mathcal{H}}{3e} a^2 \rho_y^{(0)} \left( 2a^2 \mathcal{H} \omega^{(2)i} + \epsilon^{ijk} \frac{\bar{R}^{(0)}}{a^{(0)}} \delta_v \Delta_b^{(t,1)} \delta_i^{(t,1)} \delta_j^{(t,1)} \delta_k^{(t,1)} \right). \quad (A.10)
\]

This result is the same as equation (76).
